THE TREATMENT OF DELIRIUM TREMENS

KARL M. BOWMAN, M.D.
HERMAN WORTIS, M.D.
AND
SYLVAN KEISER, M.D.
NEW YORK

Beyond the fact that delirium tremens occurs in habitually severe and chronic alcoholism and that it frequently follows injuries, operations and acute infections, little is known of the actual etiologic factors at play. Since this syndrome was adequately and accurately described as long ago as 1813,[1] it seems remarkable that no real attempt has been made to study the physiologic and chemical changes which accompany it. The more recent therapies,[2] which have included various means of dehydration and repeated spinal drainage, are all based on the observation that at autopsy persons with delirium tremens frequently show cerebral edema. Such therapy, however, takes no account of the generalized dehydration and manifest toxicity which all these patients show and, furthermore, ignores many pathophysiologic phenomena which not only exist in these patients but are probably of at least equal importance.

In the prodromal period of delirium tremens the patient often experiences a disgust for alcohol sufficient to cause abstinence for several days. The acute gastritis and hepatitis which so many patients have often makes it impossible for them to retain anything by mouth, including alcohol. It is this type of abstinence which has often been mistakenly considered a cause rather than a result of delirium tremens. The studies of Piker[3] showed conclusively that between 75 and 90 per cent of patients have delirium tremens while still drinking. The administration of alcohol, therefore, either to prevent delirium tremens or as a subsequent therapeutic measure has no basis in fact and, furthermore, often presents an unsurmountable psychologic barrier in the further treatment of such patients. As additional proof of the minor importance of abstinence in the production of delirium tremens it is noteworthy that in only a few of the 10,000 alcoholic addicts admitted each year does delirium tremens develop in the ward. It is our impression that, even in these few, toxic and infectious factors play a far more important part in the production of the delirium.

Restraints are gradually being abolished in the treatment of delirious patients.[4] It is our belief that mechanical restraints are usually not necessary in the treatment of delirium tremens unless the nursing personnel is too limited to protect the patient from possible injury. Then it may be necessary to use hand restraints for a short period until the patient is quiet. Otherwise, if the patient is restrained for a longer period, much of the dehydration and exhaustion which occur follows his thwarted attempts to free himself.

Sedative medication is usually necessary, but here again a warning must be issued—particularly against the use of morphine. Not only does this drug raise the intracranial pressure[5] but it frequently masks the signs of an associated intracerebral or intra-abdominal injury. It has been aptly said that morphine not only puts the patient to sleep but also puts the physician to sleep. If after a thorough physical examination it is felt that sedative medication must be given in the interests of either the patient or the ward, paraldehyde, 2 or 3 fluidrachms (7 to 11 cc.) given by mouth or rectum, in repeated doses if necessary, is the drug of choice. In agreement with Piker and Cohn[6] we believe that paraldehyde is the most innocuous, the most rapidly eliminated and the most uniformly effective of all sedative medicaments in the treatment of the alcoholic delirium. If a continuous tub is available and the patient's temperature is not too high, we advocate hydrotherapy as a valuable agent in the treatment of alcoholic delirious states.

When these preliminary details have been cared for, we are confronted with the problem of readjusting the deranged metabolism. It has now been repeatedly confirmed that alcohol markedly decreases the oxygen consumption of the brain,[7] presumably like all narcotics by displacing the metabolites present at the surface of the brain.[8] Ordinarily the brain tissue has a respiratory quotient of unity, indicating that the brain feeds essentially on dextrose.[9] That this normal nutritive material is not available to the brain in the alcoholic delirium is suggested by the fact that in alcoholic dogs the

respiratory quotient of the brain falls from unity to 0.8 or 0.9,[10] indicating either that carbohydrates are not available for use or that the brain by virtue of the insult suffered is unable to utilize available carbohydrate and must turn to other foodstuffs. At any rate, whatever the cause, it would seem important to make dextrose, the normal food of the brain, available. This carbohydrate may be supplied in any form, but orange juice, containing in addition vitamin C, is a readily digestible and easily obtained source of this material. Furthermore, alcoholic addicts seem to like it and are able to retain it. Recent unpublished work at Bellevue indicates that dextrose accelerates the elimination of alcohol and that, if insulin (average dose of 15 units) is added, alcohol disappears from the blood still more rapidly. In addition, it results in more rapid assimilation and utilization of carbohydrates. As there is evidence of hepatic dysfunction[11] in all cases of delirium tremens, administration of dextrose undoubtedly helps to remedy the deranged metabolic processes therein.

The empiric observations of Bowman and Keiser[12] revealed that disturbed alcoholic patients quiet down after the administration of sodium chloride, either by mouth or parenterally. Chemical studies[13] showed that the chloride content of the blood was either low or markedly diminished in these states. To remedy this defect, capsules containing 2 Gm. of sodium chloride are given every four hours to these patients. The administration of the substance serves two purposes: 1. It combats dehydration.[13] 2. Since the alcoholic delirium is associated with a marked acidosis resulting not only from accumulated lactic acid in the blood and spinal fluid[14] but also from retention[16] of carbon dioxide, there ensues a marked diminution in the alkali reserve of the body which is successfully combated by administration of the sodium ion.

Repeated feedings of a soft diet rich in vitamins is of inestimable value in the treatment of these patients. If possible, the diet should contain from 3,000 to 4,000 calories a day. It is now generally accepted that vitamins B and A play an important part in the normal metabolism of nervous tissue.[14] Furthermore, Jolliffe and Frank[15] demonstrated a high incidence of peripheral neuritis in alcoholic addicts admitted to the psychiatric department of Bellevue Hospital as a routine indicating a deficiency of vitamin B_1. Moreover, Wortis, Wortis and Marsh[16] have shown that patients in alcoholic delirium have subnormal amounts of vitamin C in the blood and cerebrospinal fluid, a defect not present in alcoholic addicts without neurologic or mental changes. Alcoholic pseudopellagra is a common occurrence in our wards. While no definite conclusions can be drawn from these facts, the observations emphasize the importance of nutritional factors in the production of the alcoholic delirium. In addition, there is reason to believe that vitamins A and C play an important part in preventing and combating infection.[17] Since it is complicating infections which make the prognosis bad in cases of delirium tremens, the importance of vitamin therapy in this respect should not be underestimated. All the vitamins are now available in concentrated form, and vitamins B and C may even be injected intravenously.

During the stage of active delirium patients are so toxic and dehydrated that any attempt to limit fluids because of the associated cerebral edema seems to us shortsighted. It has therefore been our practice to place these patients on a regimen of relative hydration, giving from 3,000 to 4,000 cc. of fluid a day.

Piker,[18] in a clinical evaluation of the use of fluids in delirium tremens, altered his original stand somewhat and suggested that fluids be given according to the patient's needs and not limited to less than 1,000 cc. a day, as he and Cohn[9] formerly suggested. We would go further than this and insist that unless general medical indications, such as edema, cardiac failure or nephritis, exist, fluids to the extent of 3,000 to 4,000 cc. a day be forced on all these patients. It has, in fact, been a not uncommon observation that the fluid itself acted as a sedative and that the patient immediately went to sleep, so that no further medication was necessary. High enemas should be given in a routine way both for the relief of chronic constipation, which is common in these cases, and for the definitely quieting effect they have on overactive, disturbed patients. They also provide additional fluids in dehydration.

Many alcoholic addicts have rigid pupils on admission. Failure to rule out syphilis may lead to serious consequences. At least 10 per cent of our patients with syphilis of the central nervous system are admitted to the hospital in an acutely alcoholic condition. Kennedy and Herman Wortis[19] have already stressed the importance of alcohol as a factor in the production of cranial injury. We wish therefore to make it clear that lumbar puncture performed on admission of these patients is for diagnostic purposes only and not for the specific treatment of delirium tremens.

The prognosis of delirium tremens is adversely affected by the presence of precipitating and complicating factors. It is therefore considered advantageous to work in close cooperation with the medical and surgical staffs of the hospital, and any patient who does not respond satisfactorily to our aforementioned treatment is seen in consultation with physicians on these services. The complications most usually encountered in delirium tremens are:

1. Cranial injuries, including fractures of the skull, contusions and lacerations of the brain and subdural and epidural hemorrhages. For these injuries we have found it inadvisable to use the routine dehydration therapy for head injuries[9] and have usually forced fluids. In cases of subdural and epidural hemorrhage, operation is of course necessary.[19]

2. Fractures, particularly of the extremities and ribs.

3. Infections of the lungs or of the upper part of the respiratory tract.

4. Focal infections which are often difficult to locate. The streptococcus is a frequent offending organism.

5. Vasomotor collapse. The mechanism is not at all clear. Piker and Colm [6] suggested that the etiologic factor may be toxic myocarditis and digitalized their patients as a routine. This suggestion is worth further consideration.

While we agree that the chief factors contributing to the clinical picture of delirium tremens are the somatic ones, e. g. infections, a lowered chloride content of the blood, lowered vitamin reserves, increased lactic acid in the blood and spinal fluid, liver damage and so on, we feel it important not to disregard the psychogenic factors. It must be fully realized that the clinical picture can be considerably influenced by the personality of the patient. Since fear is usually the primary affect in these alcoholic delirious states, it is well to keep the patient in a neutral environment, to shift the nursing personnel as little as possible and to reassure the patient constantly concerning his fears and hallucinations.

It should be emphasized that our patients with delirium tremens were seriously ill and formed a group of the most violent patients who were treated in the disturbed ward of this psychiatric hospital. The sole fact that they had delirium tremens, whether with complications or not, determined our choice of patients for this study. In six months prior to the use of this treatment there were ninety-two cases of alcoholic delirium, with sixteen deaths, a mortality rate of 16 per cent. During a subsequent period of the same duration, among the sixty-five patients treated by this new method there were but three deaths, making a mortality of 4.6 per cent.

To date we have confined our treatment to patients in the disturbed ward of the psychiatric department of Bellevue Hospital. We are expanding this study to include patients suffering from delirium tremens in other parts of the hospital. These results we shall subsequently report.

In treating alcoholic delirium we emphasize the following procedures:

1. Withdraw alcohol abruptly.
2. Give sedative medication judiciously, paraldehyde being preferred and morphine condemned.
3. Omit restraints unless absolutely necessary.
4. Give carbohydrate in large quantities.
5. Administer sodium chloride in an attempt both to combat dehydration and to restore the normal acid-base equilibrium of the body.
6. Provide a high calory, high vitamin diet.
7. Force fluids.
8. Do lumbar punctures for diagnostic purposes only.
9. Treat complicating or precipitating factors with specific therapy.
10. Give individual psychotherapy according to the needs of the patient.

The Organic Basis of Crime.—Psychiatry has shed some light on the causation of crime, but it is baffled by the intangibility of psychological processes. If one could put his finger upon a mental defect as upon a wart, or could measure a subnormal mentality with a clinical thermometer, the task of the psychiatrist would, at least, be simplified. At present the diagnosis of mental disease and the determination of mental defect remain somewhat fuzzy, and subject to personal equation. . . . The absence of norms for mental states is partially due to the abstract quality of psychological processes.—Hooton, Earnest Albert: Crime and the Man, Cambridge, Mass., Harvard University Press, 1939.

THE PROGNOSIS AND SUBSEQUENT DEVELOPMENTS IN ACUTE RHEUMATIC PERICARDITIS

EDWARD MASSIE, M.D.
ST. LOUIS
AND
SAMUEL A. LEVINE, M.D.
BOSTON

There is a dearth of information concerning the subsequent developments and final outcome of cases of acute rheumatic pericarditis. Although this condition is frequently seen and has often been studied during its acute phases, the difficulty of tracing and following the same persons for long periods after the immediate recovery has occurred probably accounts for the lack of careful observations concerning its ultimate outcome. It is not our purpose here to ascertain the incidence of acute rheumatic pericarditis but rather to study the immediate mortality and the future course of this disease. Numerous and varied contentions have been made concerning these points, but there are very few critical data on this subject.

Carter [1] has indicated that pericarditis occurs in from 6 to 25 per cent of cases of acute rheumatic infections. The great variation in the incidence according to different authors no doubt depends on the fact that the clinical diagnosis can easily be missed if the friction rub is not heard and that studies limited to postmortem data will show a high incidence of pericardial involvement. This is clearly borne out by the study of Bland and Jones,[2] who found that 35 per cent of 135 patients who died of rheumatic fever had a pericardial friction rub during their terminal illness. On the other hand, 55 per cent of those examined post mortem showed evidence of acute pericardial inflammation. As to prognosis, White [3] properly emphasized the fact that "the immediate prognosis in acute pericarditis is good as a rule in the nonpyogenic infections in spite of well marked symptoms and signs." On the other hand, Findlay, Macfarlane and Stevenson [4] in a study of rheumatic pericarditis in childhood found that both the immediate and the remote prognosis are serious. Numerous investigations have been carried out on the prognosis of rheumatic fever in general, but little attention has been paid to the role that pericarditis, per se, might play in these cases.

MATERIAL FOR THIS INVESTIGATION

In this study all the cases of definite acute rheumatic pericarditis seen at the Peter Bent Brigham Hospital during the years 1913-1937 and those seen in consultation by one of us were investigated. There were 106 of the former and twenty-nine of the latter, a total of 135 cases. A few of the hospital patients had had acute pericarditis in the Children's Hospital and were subsequently under our care. In the main, the diagnosis rested on the finding of a typical to and fro pericardial friction rub, the presence of pericardial effusion and other stigmas of rheumatic infection.

In this series there were eighty-six males and forty-nine females. The predominance of males has also been

found in previous reviews. The youngest patient was 3 years old and the oldest was 57. The average age of the entire group was 19.6 years. The distribution in the various decades is indicated in table 1. The greatest incidence was in the second decade, in which more than half the cases occurred. The number of patients under the age of 12 years is less than would be obtained in a more comprehensive study, since patients under the age of 12 are not ordinarily treated at the Peter Bent Brigham Hospital.

It is well known that rheumatic fever may manifest itself without the presence of typical polyarticular rheumatism and in fact without any pains in the limbs at all. The symptoms of this disease may be entirely or mainly confined to the heart. It is true, however, that when such a situation arises very close questioning may uncover the fact that there have been mild aches or pains in the limbs. Of our entire series of 135 cases the acute pericarditis was accompanied by definite arthritis in 110 instances, in eleven of which the symptoms consisted mainly of mild pains in the limbs. Very painful joints were uncommon. In the remaining twenty-five cases, pains in the muscles or joints did not occur. One of these cases presented typical chorea with the acute pericarditis. Of the other twenty-four patients without either arthritis or chorea, seventeen had a past history of one or more attacks of rheumatic fever with or without residual valvular disease and the others had a history of frequent tonsillitis or a family history of rheumatic heart disease. To be sure, many of the patients who had arthritis with the acute pericarditis also had a past history of rheumatic infection. In fact sixty-nine patients, or 51 per cent of the entire series of 135, had such a past history. This included eight patients who had both rheumatic fever and chorea and four who had chorea alone.

TABLE 1.—*Age and Sex Incidence*

Decade	Cases		Sex	
	Number	Per Cent	Males	Females
0-9	15	11.1	10	5
10-19	76	56.3	49	27
20-29	23	17.0	15	8
30-39	14	10.4	10	4
40-49	5	3.7	2	3
50-57	2	1.5	0	2
Total	135	100.0	86	49

IMMEDIATE MORTALITY

The immediate mortality of the entire group was 16.3 per cent. The duration of the acute illness in these fatal cases varied from one to eighteen weeks, with an average of five weeks. There was a slight indication that the disease was more serious in the younger patients, for the average age of the fatal group was 16.3 years, in contrast to an average age of 20.2 years for those who recovered. Apart from this factor of age there did not seem to be any differences between the fatal and the nonfatal cases. The occurrence of pericardial effusion, presence or absence of rheumatic pains, the sex distribution and the past history of rheumatic fever seemed to be the same in the two groups of cases. Six of the patients who died during the acute attack were examined post mortem, and they all showed evidence of acute involvement of the pericardium and myocardium.

SUBSEQUENT DEVELOPMENTS

The problem that interested us particularly in this study was the subsequent progress and developments in those patients who recovered from the acute rheumatic pericarditis. Many of these patients had their acute infection a long time before. Despite this, follow-up notes were obtained as to the present status or ultimate outcome in 104 of the 135 cases. It was impossible to trace the subsequent history of thirty-one patients. Twenty-two patients died of the acute infection. This group has already been discussed. An additional twenty-five patients died a considerable time after recovering from the acute pericarditis. The average duration of life of this fatal group after the onset of acute pericarditis was 6.7 years, the interval varying from six months to seventeen years. Twelve of these patients died of heart disease, five of pneumonia, two of incidental illnesses and six of unknown causes.

It was possible to ascertain the subsequent subjective or objective status in eighty-two instances some years after the primary infection. In seventy of these, data obtained on careful physical examination were available. Of twelve additional patients only the general health was known. The average time elapsed between the acute pericarditis and the final examination or follow-up note was a little over seven years, the interval varying from one to seventeen years. The most striking fact that was learned in following these cases was that, after the twenty-five fatalities were eliminated, fifty-two of the fifty-seven remaining patients were in satisfactory condition and able to carry on essentially normal activities.

Even more impressive than the general feeling of good health that was present in most of the living patients was the frequency of only minimal evidence of organic heart disease on physical examination. Table 2 indicates the diagnoses of the valvular condition at the time of the last follow-up examination. The term potential heart disease is used only for those cases in which there were no symptoms of cardiac disability and either no murmurs whatever or only a faint grade 1 systolic murmur.[5] The seventy cases were divided into two groups: those with and those without a history of rheumatic fever or rheumatic heart disease previous to the acute pericarditis. There were thirty of the former and forty of the latter. It is interesting that twenty-five of these seventy patients were still regarded as having potential heart disease many years after the acute pericarditis; in fact fifteen of these twenty-five patients had no murmurs whatever and showed no signs or symptoms of heart disease. In ten additional patients there was a systolic murmur sufficiently loud to be classified as mitral insufficiency. Practically all of these patients were symptom free. The remaining thirty-five patients had major lesions of the mitral or aortic valves or both. Even most of these had a good cardiac reserve and were carrying on satisfactorily. Apart from the incidence of benign or insignificant valvular lesions in the group as a whole, it is noteworthy that a large number of patients without a previous history of rheumatic infection proved to have only potential heart disease. Whereas only five of the thirty cases with a previous history of rheumatic infection subsequently showed minimal involvement of the heart (potential heart disease or mitral insufficiency), thirty of the forty cases without such previous history fell into this group. It follows that even after a severe bout of rheumatic peri-

5. Freeman, A. R., and Levine, S. A.: The Clinical Significance of the Systolic Murmur, Ann. Int. Med. 6: 1371 (May) 1933.

carditis recovery can frequently be so complete that years later there may be no signs or symptoms of heart disease. This was found to be particularly true if there was no previous rheumatic infection.

ROLE OF ACUTE PERICARDITIS PER SE

An attempt was made in this study to investigate the role that pericarditis per se might play in the subsequent progress of those patients who recovered from the acute infection. For this purpose the conditions that were present in the heart before the acute pericarditis, those immediately after the acute infection and those detected years later were compared whenever such data were available.

TABLE 2.—*Valvular Lesion on Follow-Up Examination*

Diagnosis	Cases With History of R F.* or R H D.* Prior to the Acute Pericarditis		Cases Without History of R F. or R H D. Prior to the Acute Pericarditis		Both Groups	
	Number	Per Cent	Number	Per Cent	Number	Per Cent

Total cases	30	100.0	40	100.0	70	100.0

* R F, rheumatic fever; R H D, rheumatic heart disease

There were seventy cases in which the valvular diagnoses made immediately after the subsidence of the acute pericarditis could be compared with the observations made in the follow-up examination performed years later. The anatomic diagnoses in these cases are indicated in table 3. It is very significant that twenty-two patients who were regarded as having potential heart disease after the acute pericarditis showed no more evidence of cardiac involvement in the follow-up study. In fact in three additional cases in which the systolic murmur was loud enough to merit the diagnosis of mitral insufficiency so little was heard in the heart in the follow-up examination that the diagnosis was changed to potential heart disease. There were also eleven cases of mitral insufficiency in which there was no change in subsequent years. There were twenty-two other instances presenting various types of valvular disease in which the condition remained stationary. It is interesting that of the twelve patients who had progressive lesions nine had recurrent rheumatic fever during the intervening years after the attack of pericarditis. There were therefore only three patients who showed further involvement of the valves of the heart that might be regarded as a natural progression of the original injury, without any obvious new infection occurring. In recapitulation it is evident that fifty-eight of the seventy cases did not show any progression (three of these, in fact, retrogressed) while evidence developed in twelve of new valvular involvement or stenosis of a valve previously insufficient.

The effect of the acute infection was further studied in a small group of cases in which the anatomic diagnosis was available before and directly after the pericarditis. There were nine such cases, all of which presented clearcut mitral stenosis and insufficiency. Five of these patients had aortic insufficiency in addition. Three of these nine patients had further involvement of the valves on follow-up study but all three had a subsequent attack of rheumatic fever. In only one instance was there evidence that a new lesion of the valve (aortic insufficiency) developed during the attack of acute pericarditis.

X-RAY EXAMINATIONS

In none of the patients who were examined years after the acute pericarditis was there any clinical evidence of constrictive pericarditis. This was rather striking, notwithstanding the fact that the eight patients who were examined post mortem (six who died during the acute attack and two who died in subsequent years) all showed either fibrinous or fibrous pericarditis. X-ray examination of the heart was made in six cases from one to sixteen years after the acute pericarditis. Careful fluoroscopic study and roentgenkymography were carried out. In none was there any calcification or other evidence of pericardial constriction. The x-ray appearances in the cases that presented valvular disease were those customarily seen with such lesions and in the two that presented no heart disease the roentgenograms were entirely normal. These results are in accord with previous observations [6] that rheumatic pericarditis is rarely if ever a cause of constrictive pericarditis.

ELECTROCARDIOGRAPHIC APPEARANCES

No attempt was made here to investigate the changes in the ventricular complex which accompany acute pericarditis. This has recently been carefully analyzed by Bellet and McMillan.[7] We were interested, however, in tracing what happens to the PR interval, which is so commonly involved. Of ninety instances in which electrocardiograms were taken in the acute attack, eighteen showed delay in the PR interval. Of thirty-one patients reexamined in this follow-up study, nine had delayed auriculoventricular conduction. Four of these nine had also had essentially the same degree of delayed conduction during the acute attack. Two of these four, how-

TABLE 3.—*Comparison of Valvular Diagnoses Made Immediately After Acute Attack and on Follow-Up*

Number of Cases*	Diagnosis Immediately After Attack	Diagnosis on Follow-Up
22	Potential heart disease	Potential heart disease

3	Aortic insufficiency, aortic stenosis, mitral insufficiency, mitral stenosis	Aortic insufficiency, aortic stenosis, mitral insufficiency, mitral stenosis

* Number in parentheses indicates number of cases in which one or more attacks of rheumatic fever occurred in interval between the acute pericarditis and follow up examination when progression of valvular lesion occurred

6 White Heart Disease, p 237.
7. Bellet, Samuel, and McMillan, T M: Electrocardiographic Patterns in Acute Pericarditis, Arch Int Med **61**: 381 (March) 1938.

disease, and an additional 14 per cent had only mitral insufficiency. In the remaining cases aortic valvular involvement seemed to be more common than one would expect in an average group of rheumatic patients. Even after a desperately severe attack of acute pericarditis recovery was often complete, so that many cases showed subsequently neither subjective nor objective evidence of heart disease.

8. A comparison of the examinations made before, immediately after and many years subsequent to the attack of acute pericarditis showed that new involvement of the valves was uncommon unless another attack of rheumatic fever intervened.

9. Delayed auriculoventricular conduction on rare occasions persisted many years after an attack of acute pericarditis. Auricular fibrillation or flutter occasionally occurred as a transient phenomenon, and when the arrhythmia was persistent it was always associated with mitral stenosis.

10. X-ray or clinical evidence of constrictive pericarditis did not occur in any instance.

11. This study emphasizes the great importance of injury to the valves of the heart in the subsequent prognosis of acute rheumatic infections and the minor role that the heart muscle or pericardium plays after recovery occurs from the acute infection.

INHALATION THERAPY OF BRONCHIAL ASTHMA

JAMES B. GRAESER, M.D.

OAKLAND, CALIF.

The possibility of obtaining relief of asthmatic symptoms by the direct application of a solution of epinephrine to the bronchial mucosa was reported by Ephraim [1] as early as 1910. Through the bronchoscope he first observed blanching of the mucous membrane after subcutaneous administration of epinephrine. Subsequently, epinephrine solution was sprayed directly into the bronchi through the bronchoscope with definite relief of asthmatic symptoms. In a later communication Ephraim [2] repeated these observations and commented on the beneficial effect of procaine hydrochloride alone, although he said that greater benefit resulted from the epinephrine. Thereafter, other authors reported the efficacy of the inhalation of epinephrine solutions for the relief of asthmatic symptoms. The earler of these were Krause,[3] Segel [4] and Zuelzer.[5]

In later years a number of reports have been made concerning this procedure, such as those of Grunwald,[6] Sachse,[7] Weiss and Magassy,[8] Camps,[9] Knipping, Lewis and Moncrieff,[10] Poras [11] and Lageder.[12] In Europe a number of epinephrine solutions have been marketed under patented names and various atomizers devised for use with them. Combinations of epinephrine with local anesthetics and other endocrine and drug preparations have been recommended by different authors. "Glycerinan," a solution of epinephrine in salt solution and glycerin, was used by Sachse,[7] Lageder [12] and others. "Tonolysin" was reported on by Weiss and Magassy [8] and "apneugene" by Camps.[9] "Bronchovydrin," a combination of pituitary extract, epinephrine and papaverine, was favorably reported on by Poras.[11] Inhalation periods varying from five to twenty minutes were apparently necessary with all these preparations, suggesting that the actual epinephrine content of the solution was low, probably in the 1 : 1,000 range. Both rubber bulb and motor-driven atomizers were used.

Lageder [12] was the only author who mentioned the use of a more concentrated epinephrine solution. In his studies on the effect of the inhalation procedure on lung ventilation he cited the occurrence of systemic effects following inhalation of a 1 : 200 solution of epinephrine. No comment was made, however, with regard to the use of the stronger solution in actual therapy.

The first report on the therapeutic value of inhalation of a more concentrated epinephrine solution (1 : 100) was made in 1935 by me.[13] Other reports have been made by Matzger,[14] Nielsen [15] and again by me.[16]

Subsequent observations have been made on patients using the 1 : 100 epinephrine solution for more extended periods. An attempt has also been made to work out more thoroughly the question of the most suitable dilution of epinephrine. Furthermore, certain comparisons have been made between the use of a 1 : 100 solution of epinephrine and the use of other drugs. These studies are the subject of the present report.

METHOD

The hand atomizer with the rubber bulb and the general technic previously described [17] were used. Atomizers of more than average efficiency from the point of view of volume and fineness of spray were selected. The patients chosen were all chronic sufferers having persistent symptoms. Before beginning the experiment all had been using the inhalation procedure for from several weeks to several months with varying degrees of success. Dilutions of the 1 : 100 epinephrine solution [18] were made with physiologic solution of sodium chloride. Several dilutions were given to each patient at one time, labeled in code, always including the 1 : 100 dilution. In some instances two atomizers were given to the patient so that immediate comparisons could be carried out without changing the solution in the atomizer. The dilutions given were changed frequently under different code numbers until the observations

reported by the patients assumed some degree of consistency. The extreme variation in the reports of results of the use of the same dilution on different occasions necessitated repeated trials over periods of several months. Salt solution alone was given in a number of instances.

RESULTS

The accompanying table summarizes the results of these experiments. The degrees of relief obtained were roughly graded as "excellent," "moderate" and "slight," and as recorded in the table represent the average of the reports submitted. "Excellent" results were not constantly so, but the term as used signifies that in attacks of average severity excellent results were obtained. Not infrequently during severe symptoms only "moderate" or "slight" relief would be obtained. "Slight" relief likewise signifies an average result. During very mild symptoms "excellent" relief might be obtained with the more dilute solution. Several patients reported good relief on some occasions from salt solution alone. Confusing evidence of this type is to be expected in evaluating a therapeutic procedure on a subjective basis in the treatment of a disease as variable as asthma. Some patients not included in the table submitted results so consistently inconsistent that they were discarded. The results summarized in the table, therefore, are averages of repeated trials of the several dilutions of epinephrine.

Degrees of Symptomatic Relief of Asthma Following Inhalation of Dilutions of Epinephrine, Ephedrine and Neosynephrin

From the table it is apparent that the 1:100 dilution of epinephrine proved to be the most effective of the solutions used under the conditions of the experiment. The patients did not always inhale the same number of breaths of vapor-laden air. The average time of inhalation, intermittent as it would necessarily be with the hand apparatus, varied between one and four minutes. Continuous inhalation with a motor driven apparatus, with inhalation through a mask, would probably have given the same results more consistently in less average time. With the motor-driven apparatus systemic effects from epinephrine are frequently obtained with continuous inhalation of the 1:100 dilution for two minutes, but such effects rarely occur when the hand apparatus is used for this length of time.

A 2 per cent solution, or a 1:50 dilution, of epinephrine was used by twelve different patients. With the same number of inhalations there were more frequent reports of systemic symptoms, such as headache, tremor and palpitation, without appreciably more relief of the actual asthmatic symptoms. Two of the twelve patients felt that the stronger solution was decidedly superior, but they likewise experienced systemic symptoms, though mild, much more often, whereas these rarely occurred with the 1:100 dilution. As a result of these observations it was felt that the stronger solution was not sufficiently advantageous for recommendation for general use, for in the mild or moderately severe paroxysms of asthma, for which inhalation of an epinephrine solution is the most effective, the 1:100 dilution was just as beneficial as the 1:50 dilution. Another consideration which of necessity must enter into this conclusion is the added cost of the stronger solution. Furthermore, when the 1:100 solution fails to relieve the attacks after several trials it is advisable to resort to hypodermic administration to obtain relaxation of the bronchi if the patient still responds to epinephrine. After relief is obtained the inhalation procedure often serves to abort subsequent severe paroxysms.

Epinephrine and Solution of Posterior Pituitary.—One of the preparations previously mentioned [11] contained these two substances. A solution of equal parts of 1:100 epinephrine solution and 1:1,000 solution of posterior pituitary was prepared and used in twelve cases. The results obtained were comparable to those recorded in the table from the use of a 1:200 dilution of epinephrine. No appreciable enhancement of effects occurred from the addition of the pituitary solution.

Ephedrine Sulfate.—A 10 per cent dilution in physiologic solution of sodium chloride was prepared and used under the conditions of this experiment. No benefit resulted even with more prolonged periods of inhalation. The patients complained of a bitter taste and dryness of the nasopharynx but not of the nervousness or palpitation.

Neosynephrin.—A 5 per cent solution was of no benefit in five instances.

Cocaine.—A 1 per cent cocaine solution was tried by ten patients. Two of these reported benefit comparable to that obtained with the 1:100 epinephrine solution. Six reported moderate benefit and four none. The relief was not as marked as with the epinephrine solution. A comparison was also made by six patients with a patent preparation containing a 1 per cent cocaine mixture with nitrites. The results were about the same as with the pure cocaine solution; that is, under the conditions of the experiment the preparation was definitely less efficient than the epinephrine solution.

Extended observations were not made with the preparations other than epinephrine. They were used simply to determine the possibility of obtaining relief of asthma by an entirely different type of drug.

COMMENT

To attain either a local effect on the mucous membrane or a general therapeutic effect from inhalation of drugs one must attain a minimal effective concentration on the membrane. This is dependent on at least three factors, namely the absorptive power of the bronchial mucous membrane, the density of vapor in the inhaled atmosphere and the actual amount of vapor deposited on the mucosa. Heubner and his co-workers [19] have conducted many animal experiments on inhalation of dye solutions under varying experimental conditions. By this means they were able to demonstrate widespread dissemination of dye throughout various organs of the body. Within the bronchial tree the largest concentra-

19. Heubner, W.: Ueber Inhalation zerstander Flüssigkeiten, Ztschr. f. d. ges. exper. Med. **10**: 269, 1920.

tion of dye, as shown by intensity of color, occurred at the carina and bifurcations of the larger and smaller bronchi. Penetration of the dye in the peribronchial mucosa was also noted. Very little is known, however, of the actual absorptive power of the different portions of the respiratory tract. It is generally assumed, though not definitely proved, that the lower portions have the higher absorptive power, but there is considerable divergence of opinion as to how deep into the bronchial tree vapor droplets are actually carried. This was discussed in detail by Heubner.[15] He demonstrated a definite relationship between the depth of respiration and the transport of droplets and expressed the opinion that vaporized liquid droplets can enter the field of the smaller bronchi if they are of suitable size and the vapor is of sufficient density. Clear demonstration of this penetration is difficult.

The density of vapor is dependent on the apparatus used for vaporization. A spray of high density is necessary for obtaining maximum results in inhalation therapy. Very few of the atomizers available for use with the epinephrine solution are efficient in this aspect. Furthermore, the droplets constituting the vapor must be of extreme fineness, for the reason that droplets below a certain size no longer respond to the force of gravity and so tend to follow freely the movements of the air currents in the bronchial tree.

Of importance also is the concentration of the drug solution vaporized. It must be much higher than that usually used for other routes of administration. Heubner stressed the fact that one need not fear the effect of inhalation of a concentrated solution of a drug if the vapor is of suitable fineness for few of the droplets inhaled actually to come in contact with the mucous membranes. Those actually adhering to the cell membrane are quickly diluted by tissue fluid and glandular secretion and spread widely, so that the final concentration of the drug on the mucous membrane is not at all comparable to the concentration of the solution vaporized.

The amount of the drug actually deposited depends on several factors. With deep inhalation a greater amount of the vapor will reach the smaller bronchi. Here more droplets are likely to be deposited, because of the more favorable relationship between the extent of the exposed mucous surface and the volume of vapor in the lumen of the bronchi.

It is probable also that the condition of the mucous membrane, that is, whether congested with blood, covered with mucus or atrophic, has a role in determining adherence of the droplets to the mucous membrane at the edge of the air current. Likewise the vehicle carrying the drug, i. e. salt solution, glycerin or oil, will vary its adhering qualities. Little is known concerning the latter factors.

It is obvious from this discussion that there is a great deal more to be learned concerning inhalation therapy. Continued experience with the inhalation of 1 : 100 epinephrine has demonstrated that the procedure is a valuable addition to the symptomatic therapy of asthma. The greatest benefit occurs when the symptoms are mild or moderately severe. During severe paroxysms its usefulness is limited because of the difficulty, as discussed, of obtaining penetration of the vapor deep into the bronchial tree. Failure of the procedure in many instances, however, is due to an inefficient atomizer and also to its incorrect use. Simple as the procedure is, many patients contrive to manipulate the instrument so awkwardly that very little of the vapor is actually inhaled. Too frequently the apparatus is prescribed but the patient is not instructed in its use. With small children whose cooperation is difficult to secure, to obtain some motor-driven mask apparatus, as previously described,[16] is necessary for maximum results.

In fully evaluating a procedure of this type one must keep in mind the possibility of deleterious effects from its continuous use. Such harmful reactions could be (1) increased frequency and severity of attacks resulting from irritation of the bronchial tract and (2) harmful general effects.

1. *Local Effects.*—Of a series of 162 patients using the inhalation procedure, two have been observed who became gradually but progressively worse and ultimately died. One of these patients is of particular interest, for he used the inhalation of epinephrine from three to twelve times daily from March 1935 until his death in November 1936. Both the hand atomizer and motor-driven pump were used. Attention was first called to the patient by the local pharmacist, who inquired concerning the advisability of furnishing him with such large quantities of the solution. Later the patient's dentist called attention to a rapidly developing erosion of the dentin of his teeth, which appeared about six months after he began the use of the spray and rapidly progressed. Unfortunately the patient had asthma most of the time, and, though no medication gave complete relief, the inhaled epinephrine was as effective as hypodermically administered epinephrine and much handier to use. Examination of the patient's lungs after death revealed nothing suggesting any harmful effects of the locally applied epinephrine. The other patient used inhalation much less often but frequently, nevertheless, for twenty-five months. The lungs after death gave appearances typical of asthma. Since progression of the disease in this manner has frequently been observed independent of the use of any particular drug or system of treatment, it would be incorrect to attribute the course of events entirely to the use of epinephrine.

It is not felt that the course of the disease is fundamentally altered by the use of inhaled epinephrine. Certainly many patients are made more comfortable because of the ease of obtaining relief by this means, but the asthma continues. However, no case has been observed in which it could be definitely proved that inhalation of epinephrine increased the severity of the asthma.

Some patients complain of tracheal and bronchial irritation and dryness of the throat from too frequent use. Patients vary extremely in tolerance in this regard. Those requiring inhalation frequently enough to cause uncomfortable tracheal irritation should at intervals resort to other forms of medication or to epinephrine hypodermically administered.

Increased cough is noted not infrequently immediately after inhalation. In most instances mucus is raised and the patient relieved. Similar coughing and expectoration of mucus may likewise occur after the hypodermic administration of epinephrine. The most probable explanation of this symptom is that the epinephrine (either inhaled or injected) causes relaxation of bronchial spasm or shrinkage of bronchial mucosa, which releases mucous plugs for expectoration. Inhaled smoke from the burning of stramonium preparations almost invariably causes paroxysms of coughing, usually with expectoration of more mucus than is expectorated after the use of the epinephrine spray. Several patients have been seen who for this reason still prefer stramonium preparations.

Only one patient has been seen who could not use the spray because of paroxysms of coughing resulting from tracheal and bronchial irritation.

2. *General Effects.*—As has been previously mentioned, there is a general absence of systemic symptoms such as tremor, headache and palpitation, which not uncommonly follow hypodermic administration of epinephrine. This is not invariable, however, and several patients have discontinued inhaling the 1:100 epinephrine because of severe headache. In both instances, however, a 1:200 dilution was used with moderate relief of asthma and without headache.

After observing for several years the use of this procedure and receiving queries regarding failures, I have noted no permanently harmful effects from the inhalation of the 1:100 epinephrine. One must keep in mind the possibility that continued use may not be without harm, but at present this has not become apparent from purely clinical observation.

CONCLUSION

Under average conditions the 1:100 dilution of epinephrine is the most practical for the inhalation therapy of bronchial asthma. It is definitely more efficient than the more dilute solution. In some instances a 1:50 dilution is more effective, and a 1:200 or lower dilution may be more suitable. Relief of asthmatic symptoms can also be obtained with a 1 per cent solution of cocaine, but no relief resulted from inhalation of 10 per cent ephedrine solution or a 5 per cent neosynephrin solution.

411 Thirtieth Street.

OBSCURE LOW GRADE CHRONIC INFECTIONS OF THE ETHMOID SINUSES

USE OF THE PROETZ DISPLACEMENT SUCTION FOR DIAGNOSIS

GEORGE E. SHAMBAUGH JR., M.D.
CHICAGO

The diagnosis of chronic infection of the ethmoid sinuses is one of the difficult diagnostic problems in rhinology. It is particularly difficult in those low grade chronic infections of the ethmoid sinuses in which the nasal passages appear normal on one or more examinations and in which any symptoms pointing directly to the sinuses are so slight as to be almost nonexistent and yet in which there is sufficient systemic absorption from the ethmoid infection to cause very definite systemic symptoms. It is these cases of obscure low grade infection to which I wish to call attention because they are so frequently overlooked.

Until a few years ago the diagnosis of chronic suppuration of the ethmoid sinuses depended on the examiner seeing pus coming from the middle or superior meatus after the maxillary, frontal or sphenoid sinus had been excluded as the source of the pus. A moment's reflection on how many chronic infections of the maxillary sinus would be missed if the rhinologist could neither transilluminate, take roentgenograms nor irrigate for diagnosis but had to rely solely on observing pus coming from the ostium will suggest that many chronic ethmoid infections were probably overlooked when the physician relied solely on seeing pus coming from the ostium. The x-rays occasionally came to his aid, but more often than not the x-ray examination of the ethmoids is indefinite, so that while it is valuable and fairly reliable in the diagnosis of chronic infections of the antrum and the frontal and sphenoid sinuses it has not been of much help for the ethmoid sinuses. To be sure, there were a few rhinologists who believed that low grade chronic ethmoid infection was a common and generally overlooked condition. These rhinologists diagnosed and operated on many ethmoids that others had diagnosed as normal, basing their opinion more on the symptoms than on any positive clinical manifestations. Inevitably many normal ethmoids were opened, since the symptoms on which the diagnosis was made were usually very vague and indefinite. Nevertheless some patients whom the rest of us had passed up as normal because we could find no pathologic condition in the nose were undoubtedly benefited by having their ethmoids opened and undoubtedly had a low grade ethmoid infection.

Twelve years ago Dr. Arthur Proetz introduced the displacement principle of diagnosis and treatment, and at once the diagnosis of low grade ethmoid infection was placed on an entirely new plane of accuracy. With this the whole conception of the frequency of chronic suppuration of the ethmoid sinuses is changing so that now I believe that the ethmoid is the most frequent sinus involved in acute and in chronic infections.

In his original work Proetz stressed the use of iodized oil introduced by displacement suction for the diagnosis of infections of the ethmoid sinuses. I have used iodized oil comparatively little, partly because of the added cost to the patient of additional roentgenograms and partly because I have not been convinced of the reliability of failure to fill or of delayed emptying time for the diagnosis of infection. In my experience the value of the Proetz method has been in the promotion of drainage from infected ethmoid cells; in other words, if I can get pus from the ethmoid sinus I have made the diagnosis.

The procedure that I use is briefly as follows: The symptoms, of which I shall speak further in greater detail, suggest a possible low grade chronic ethmoid infection in spite of normal appearing nasal passages on posterior as well as anterior rhinoscopy on one or more occasions. A roentgenogram is taken to rule out infection of the maxillary, frontal or sphenoid sinuses, and if any of these appear infected they are irrigated. The nasal passages, vestibule and especially the nasopharynx are then carefully cleansed of any adherent secretions. With the patient's head hyperextended in the Proetz position, the nasal passages are filled with 0.25 per cent ephedrine in physiologic solution of sodium chloride. Alternate suction and release of suction is applied from four to six times in each nostril, and if frank mucopus is obtained or is blown out into the towel when the patient sits up the diagnosis of ethmoid suppuration is made. The importance of removing any mucopus from the nose, nasopharynx or maxillary sinus before carrying out the displacement suction is self evident. In certain cases there is no immediate escape of mucopus, but an hour or two later the patient will experience a nasal or postnasal discharge of a considerable quantity of frank mucopus, and this is equally diagnostic of a chronic suppuration of the ethmoid sinuses.

Since using displacement suction in this way for the diagnosis of chronic ethmoid infections, I have been

Read before the American Laryngological, Rhinological and Otological Society in St. Louis in January 1938.

impressed by the large number of low grade chronic suppurative ethmoid sinuses that would otherwise have been overlooked. I have also been impressed by the frequency of systemic symptoms in ethmoid infections as compared to infections of the other sinuses, owing perhaps to the larger area for absorption in the ethmoid sinus.

Fig. 1 (case 3).—Sinuses of normal appearance.

These cases of obscure low grade ethmoiditis fall into five groups according to the predominating or presenting symptom.

The largest group is that in which the patient's chief complaint is pain or headache. The pain of chronic ethmoiditis may be felt in the cheek, ethmoid region, forehead, parietal region or ear. Like any sinus pain, it is worse following acute head colds and worse on bending forward. These characteristics suggest a sinus origin for the headache and yet the nasal passages appear normal in all respects and there may be no nasal symptoms whatever, while the x-ray examination may be negative for sinus disease.

CASE 1.—Mrs. E. B., aged 35, residing in the Panama Canal Zone, complained of a persistent right parietal headache for three months following a severe head cold. There were no nasal symptoms and a roentgenogram of the sinuses was negative except for a small, poorly developed ethmoid sinus on the right. Displacement suction, carried out because of the history of onset following a cold and the absence of any other demonstrable cause for the headache, removed a small amount of definite mucopus from the right nostril. This was repeated five times in the next two weeks with complete and permanent relief from the headaches.

CASE 2.—Mrs. F. D. J., aged 50, complained of neuralgic pains in the frontal and parietal region with chronic fatigue for several years. Except for a slight chronic postnasal mucoid discharge for the same period, she had no nasal symptoms and the nasal passages appeared entirely normal. A roentgenogram was negative except for a questionable thickening of the ethmoids. Displacement suction removed a small clump of mucopus from the right side. This was repeated eight times in two months, with complete relief from the headaches and 80 per cent relief from the postnasal discharge. Because of a basal metabolic rate of —16 per cent, thyroid extract one-half grain (0.03 Gm.) a day was given. Many of these patients with low grade ethmoid infections show a slightly lowered metabolic rate which Mithoefer believes is a factor in causing the ethmoid infection. I am inclined to believe that the lowered metabolism is the *result, not the cause, of the infection and that the administration of thyroid extract is usually unnecessary.*

CASE 3.—Mrs. I. E. B., aged 43, complained of rheumatic pains in the arms, dizziness, headache and fatigue for three years with a postnasal discharge for about the same period. Roentgenograms of the sinuses were negative (fig. 1) and displacement suction of the ethmoid sinuses was normal, but an hour later the patient experienced a postnasal discharge of a large amount of frank mucopus followed at once by great relief from the headache. This treatment was repeated nine times in four months with complete relief from all the symptoms. There have been two recurrences of symptoms in a year and a half. Each recurrence was relieved after a few treatments.

In the second group of cases of obscure low grade ethmoid infection the presenting symptom was an infection in a remote organ, such as iritis, neuritis or arthritis:

CASE 4.—Mrs. A. C., aged 23, complained of an acute optic neuritis and iritis of three weeks' duration. There were no nasal symptoms whatever but a roentgenogram of the sinuses showed a thickening of the right ethmoid sinus. Because of this a series of neosilvol nasal packs had been carried out elsewhere without benefit to the eye condition. Displacement suction removed at once a large amount of mucopus from the right side. This treatment was repeated for five weeks until no further secretion was obtained. The eye condition began to improve after the second treatment and went on to complete recovery.

CASE 5.—C. F. A., a man aged 28, complained of optic neuritis of eight weeks' duration, not improved by removal of the tonsils three weeks before. For four years there had been a postnasal discharge and frontal headaches. A roentgenogram showed thickening of the left frontal and ethmoid sinuses (fig. 2). The nasal passages appeared normal but displacement suction removed thick white mucus from the left side. After

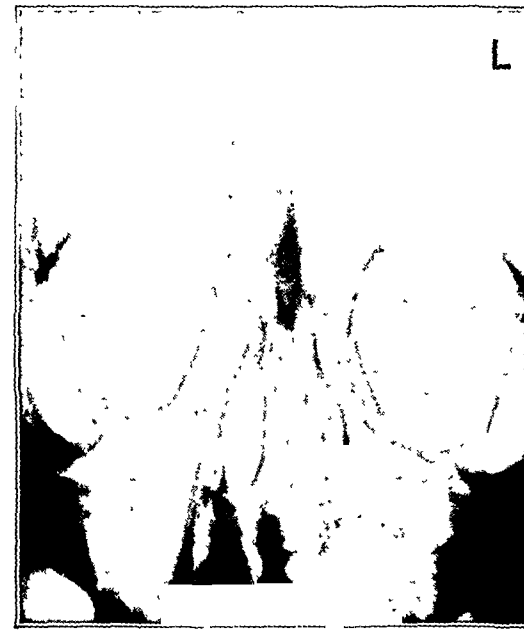

Fig. 2 (case 5).—Clouding of left ethmoid and frontal sinuses.

three weeks of this the eye condition improved but relapsed again two months later. A left intranasal ethmoidectomy, enlarging the ostium to the fronal sinus, was followed by complete freedom from the postnasal discharge and headaches for the first time in four years and by improvement in the optic neuritis.

While it may be objected that optic neuritis is often due to an undiagnosed multiple sclerosis and under-

goes a spontaneous remission, the presence of a low grade chronic ethmoiditis in these two cases cannot be denied while the close relationship between clearing up of the infection of the ethmoid sinuses and improvement in the eye condition is very suggestive of a causal relationship:

CASE 6.—D. D. P., a man aged 52, complained of tinnitus for one year. Hearing tests showed a high tone nerve deafness. For several years there had been a chronic postnasal discharge

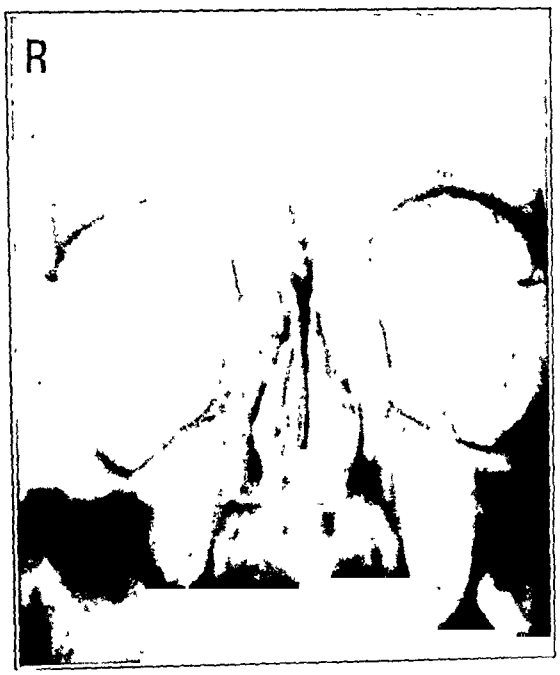

FIG. 3 (case 7).—Sinuses of normal appearance.

but no other nasal symptoms. A roentgenogram of the sinuses was negative and nasal examination was negative. Displacement suction was followed at first by an increased postnasal discharge, but after the third treatment the postnasal discharge, which had been present for several years, was entirely relieved and the tinnitus, which had been present constantly for one year, ceased.

CASE 7.—W. B., a man aged 35, had had an infectious type of arthritis for four years with a postnasal mucopurulent discharge, frequent nasal obstruction on the right and frontal headaches for the same period. Because of perfectly normal appearing nasal passages on repeated examinations both before and after the nasal mucosa was shrunk and the head was held forward, and because of negative x-ray examinations, he had been told that he did not have a sinus infection. The nasal symptoms and the arthritis continued, however, and no focus of infection for the arthritis could be found. Displacement suction removed a large clump of frank mucopus from the right ethmoid sinuses. With repeated displacement treatments the arthritis improved but the infection in the ethmoid sinuses did not clear up and mucopus was obtained each time. Finally an intranasal ethmoidectomy was followed by permanent disappearance of all arthritic symptoms one week later and permanent cessation of all nasal symptoms two week later.

The third group of patients with obscure low grade ethmoiditis complained of a chronic and persistent cough for which no cause could be found:

CASE 8.—C. D., a boy aged 10 years, had had a cough for three weeks without an antecedent cold. The previous winter he had had a similar cough for two months. A roentgenogram showed only a questionable clouding of the ethmoid sinuses, and the nasal passages appeared entirely normal. Displacement suction removed a small amount of yellow mucopus from the right side. The mucopus from the ethmoid cells and the cough disappeared after six treatments. A recurrence of cough two months later cleared up after two displacement treatments.

CASE 9.—M. S., a girl aged 10 years, had had frequent attacks of persistent bronchitis for several years. There were no nasal symptoms or abnormalities but an x-ray examination revealed clouding of the left ethmoid sinuses. Displacement suction was negative but was followed by a discharge of mucopus from the left nostril a half hour later. After five treatments the cough and the ethmoid infection cleared up. Two mild recurrences within the next four months each cleared up after one or two treatments, and since then (a year and a half) there has been no recurrence of the cough.

In the fourth group of patients the chief complaint was frequent head colds:

CASE 10.—Mrs. F. J., aged 46, complained of very frequent colds for eighteen months, coming on every few weeks and accompanied by fatigue and nervousness. Nasal examination and roentgenograms of the sinuses were negative. Displacement suction produced a moderate amount of definite yellow mucopus from the right side. After five treatments the symptoms were relieved. There have been three recurrences in a year and a half, each clearing up promptly after a few displacement treatments.

The last group of patients with obscure ethmoid suppuration had a fever of unexplained origin as the presenting symptom. This group is the most interesting to me because fever is rarely seen in chronic infections of the other sinuses:

CASE 11.—J. v. M., a girl aged 6 years, had been having an intermittent septic type of fever for six months, the temperature reaching 104 F. for about three days out of every week. Tests for undulant fever, typhoid, endocarditis, pyelitis and the like were all negative. There were no nasal symptoms, and the nasal passages appeared normal except for some redness and congestion of the mucosa. Displacement suction produced a moderate amount of mucopus from both sides. This treatment was repeated for two weeks with cessation of the fever and until no more mucopus was obtained. The fever has not recurred.

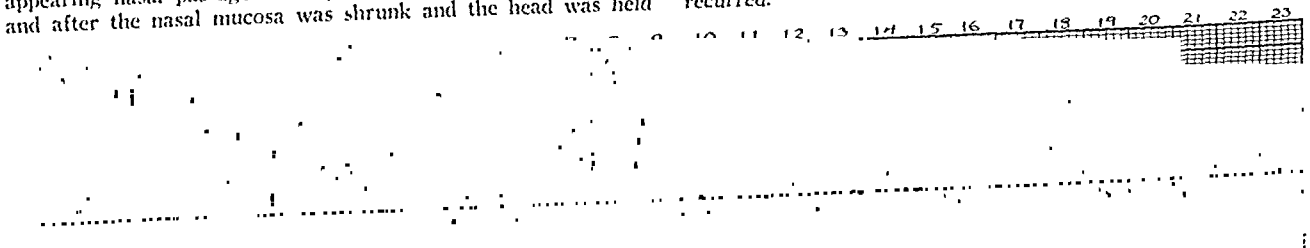

FIG. 4 (case 11).—Temperature chart during stay in hospital: *A*, mucopus from ... *D*, small, *E*, very small, amount of mucopus from ethmoids; *F*, trace of mucopus from ethmoids; *G*, only mucus from ethmoids; ... nothing removed from ethmoids.

CASE 12.—S. A., a woman aged 24, had been having a fever of from 99 to 100 F. every afternoon and evening for two and a half months for which no cause had been found. Five months before she had had a severe head cold and this had never entirely cleared up: there had been a nasal twang to the voice and an occasional sense of congestion at the base of the nose. The nasal passages appeared entirely normal and a roentgenogram of the sinuses was negative except for thickening of the left ethmoid bone. After displacement suction green mucopus appeared in the nasopharynx. After five treatments all symptoms cleared up and have not recurred.

CASE 13.—E. E. P., a man aged 41, had had a fever as high as 104 F. lasting one or two days and occurring every three or four weeks with the symptoms of a slight head cold. The nasal examination was negative; the roentgenogram showed a slight thickening of the left ethmoid sinus. Displacement suction removed a small amount of greenish mucopus from the left side. The treatment was repeated three times. There have been no further attacks of fever for one year.

CASE 14.—R. D. C., a man aged 25, complained of a low grade fever for one and a half years following a severe head cold. A window operation for a left maxillary sinusitis had relieved the fever only temporarily and there was a persistent mucopurulent discharge. Displacement suction was negative but was followed by relief from the postnasal discharge and fever. This relief, however, did not last, and a few displacement treatments would again be necessary. Finally, an intranasal ethmoidectomy was carried out and permanent relief from the fever was obtained.

CONCLUSIONS

1. The displacement method of promoting drainage from the ethmoid cells will establish a diagnosis in many cases of chronic low grade ethmoid suppuration that would otherwise be doubtful or missed entirely.

2. Displacement suction will clear up many but not all chronic ethmoid suppurations.

3. Chronic suppuration of the ethmoid sinuses may exist with slight or obscure local symptoms, the presenting symptom being headache of obscure etiology, systemic infection such as arthritis, iritis or neuritis, chronic cough, frequent head colds or fever of unknown origin.

FUNGOUS INFECTIONS OF THE HANDS AND FEET TREATED BY IONTOPHORESIS OF COPPER

PRELIMINARY REPORT

HOWARD W. HAGGARD, M.D.
MAURICE J. STRAUSS, M.D.
AND
LEON A. GREENBERG, PH.D.
NEW HAVEN, CONN.

The large number of remedies in use for the treatment of fungous infections of the feet and hands is evidence that not one is entirely successful. It is probable that all these remedies will kill fungi in vitro, but most fail to do so when applied to the skin. The fungi are in the deep layers of the epidermis, and the fungicide does not reach them. The efficacy of compound ointment of benzoic acid, the remedy most extensively employed, is due to the presence of salicylic acid, which causes desquamation with consequent partial exposure of the fungi.

The ideal method of treating fungous infections would be the introduction of a fungicide into the skin without injury to the skin. This we have attempted to do by passing copper, which is highly fungicidal, through the skin by iontophoresis. The results obtained with this therapy, reported here, are distinctly favorable. The great majority of patients treated by this method were promptly relieved of all symptoms of dermatophytosis.

Dr. Haggard is director of the Laboratory of Applied Physiology, Sheffield Scientific School, Yale University; Dr. Greenberg is instructor in the laboratory. Dr. Strauss is associate clinical professor of dermatology, Yale University School of Medicine.

Lowenfish[1] has reported the treatment of chronic dermatitis by cataphoresis with tap water. He mentioned an unsuccessful attempt to treat dermatophytosis by a method somewhat similar to the one we have used. Only nineteen patients with dermatophytosis were treated, and copper was only one of twelve chemicals used. It is possible that no extensive trial was given to copper. Lowenfish stated that a few patients showed clinical improvement but that fungi could still be found on the skin. Fungi, as has been shown, may be found on normal skin.[2] It is not the presence

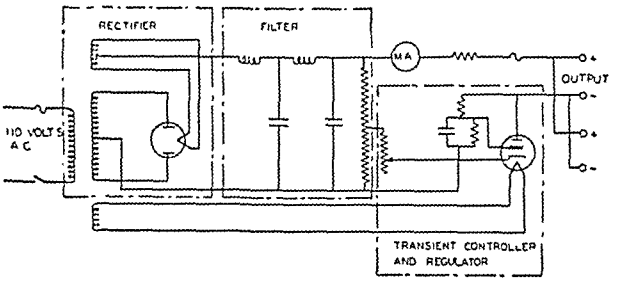

Fig. 1.—The circuit employed.

of fungi but the inflammatory process caused by them which constitutes dermatophytosis. Our results are based on the clinical changes occurring in patients whose dermatophytosis was treated by copper electrically introduced into the skin. Some of these patients may still have fungi on their feet, and probably most of them have come in contact with fungi from outside sources; but the fact remains that the majority have had relief from their symptoms and have remained clinically cured for a considerable period.

INTRODUCTION OF COPPER INTO THE SKIN

Copper was selected as the metal for iontophoretic introduction into the skin because of its well known fungicidal properties and its low toxicity. The supposition that copper could be introduced through the skin was confirmed by experiments on rats. The front legs of each rat were held in a small bath containing isotonic salt solution and the rear legs in a similar bath containing a 0.2 per cent copper sulfate solution. A copper electrode was immersed in each of the baths; that in the salt solution was connected to the negative and that in the copper solution to the positive pole of a source of direct current regulated to pass 6 milliamperes. As a control, rats were similarly immersed for twenty minutes but with no current flowing. The animals were killed and the rear legs washed thoroughly and skinned carefully to prevent any contamination from the copper solution. The legs were then incinerated in a porcelain crucible; the ash was dissolved in sulfuric acid, diluted with water, filtered and tested for copper. The determination of copper was made with a modification of the Benedict test ordinarily used for sugar. The solutions were prepared in the usual manner, except that the copper salt was omitted and dextrose added. In the presence of small amounts of copper the characteristic changes in color were obtained. This test was not sufficiently sensitive to cause a reaction from the normal copper content of tissues. The legs immersed in copper solution with no

2. Downing, J. G.; Nye, R. N., and Cousin, S. M.: Investigation of the Fungous Flora of Apparently Normal Skins, Arch. Dermat. & Syph. **35**: 1087 (June) 1937.

flow of current gave no reaction for copper. The legs immersed with the current flowing gave a strongly positive reaction for copper. A current flow of 6 milliamperes for twenty minutes should by calculation lead to the introduction of 2.37 mg. of copper. This copper after passing through the skin would be distributed throughout the body of the rats; the amount present in the legs was estimated from the tests to be about 0.5 mg.

APPARATUS USED FOR IONTOPHORESIS

In treating human beings the feet were immersed in rectangular enamel pans about 5 inches deep and the hands in bain-marie basins. Copper electrodes were used. The duration of treatment was twenty minutes. When the infection was on the feet, the hands were immersed in saline solution and the feet in 0.2 per cent copper sulfate solution; for infection of the hands the relations were reversed, and if both hands and feet were infected the solutions in the baths were changed at the end of twenty minutes and treatment was continued for an additional twenty minutes.

The positive pole of the source of current was attached to the electrode in the copper solution and the negative to that in the saline solution. Much smaller currents were used than in the experiments of Lowenfish;[2] instead of from 15 to 40 milliamperes we employed from 4 to 6 milliamperes if only one hand or foot was immersed and from 8 to 10 milliamperes if both were immersed. Early in the investigation a battery fitted with a rheostat was used as a source of current. This arrangement, as well as the apparatus used by Lowenfish, has serious drawbacks: The current can be gradually increased to prevent any shock,

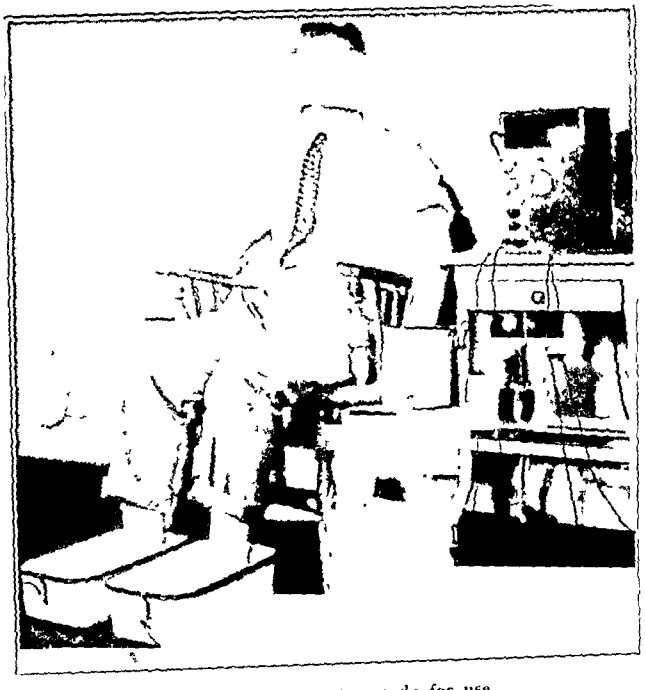

Fig. 2.—The apparatus ready for use.

but if the hands or feet are taken out and reimmersed the full strength of current is immediately received with a severe and unpleasant, possibly dangerous, shock. To avoid this occurrence it was necessary to watch each patient carefully during the entire period of treatment. To obviate the danger of shock, a special apparatus was developed for us by Prof. Albert G. Conrad of the Yale School of Engineering.[3] The circuit employed is shown in figure 1. The apparatus operates on 110 volt alternating current, which is rectified to direct current in the usual manner. The supply to the electrodes is regulated by a rheostat and read from a milliammeter. In this circuit the patient's

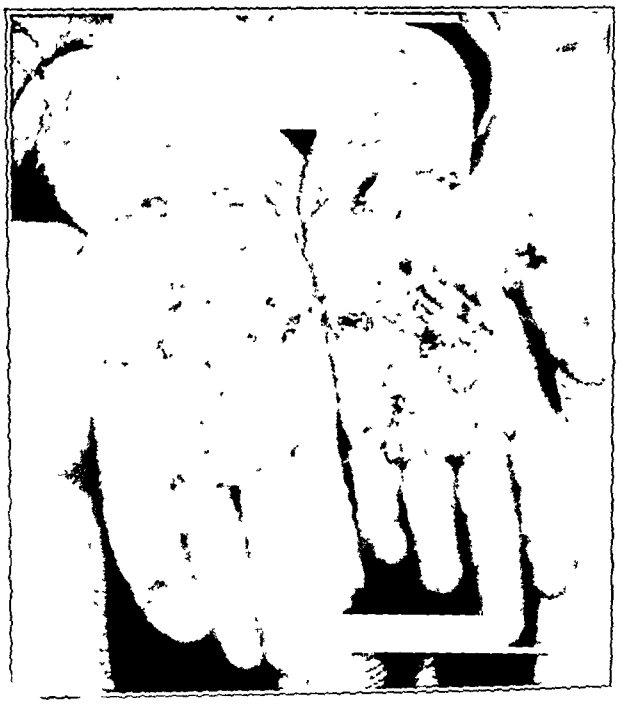

Fig. 3 (case 28).—The hands at the beginning of treatment

body acts as a switch, so that the flow of current is interrupted as soon as the hands or feet are withdrawn from the bath; it is established again when the hands are reimmersed, but the current, instead of rising instantaneously to the maximum, builds up slowly. This important feature does away with all possibility of unpleasant sensations and all dangers of serious shock; it also removes the necessity of carefully regulating the current on immersion and makes the treatment entirely safe. It has contributed materially to the facility of the method. Figure 2 shows the apparatus complete with baths for feet and hands.

PREPARATION OF THE PATIENT FOR TREATMENT

When possible each patient was treated two or three times a week. During the entire period no other treatment was used; in a few patients hydrous wool fat was applied to denuded areas to prevent the socks from sticking to the feet. The preparation of the hands and feet for immersion was found to be particularly important. The infected area was often covered with a greasy exudate which was resistant to the passage of current in precisely the regions where penetration was desired. A high resistance in these regions diverts the current and therefore the copper to the normal skin. To avoid any possible complicating factor, no means of cleaning the feet except mechanical removal of crusts and the use of soap and water was employed in the cases reported here. Since the completion of this series, however, a preliminary soaking of the feet or hands for a few minutes in a dilute solution of sodium hypochlorite has been found highly efficacious in preparing the skin for treatment.

3. The apparatus was assembled in a form suitable for clinical use by the Mine Safety Appliances Company of Pittsburgh.

RESULTS

Treatment was given to thirty-seven patients. The diagnoses of dermatophytosis were made clinically. Twenty of the patients had shown clinical signs of infection for more than a year and one for twenty-five years. The majority of the infections were severe and of long standing. Unquestionably in some patients with lesions on both feet and hands those on the hands may have been dermatophytides containing no fungi but appearing as an allergic manifestation. This possibility was ignored, and the hands were treated as well as the feet.

The accompanying table gives the clinical data concerning each patient and the results obtained from treatment. The types of eruption are designated as

Fig. 4 (case 28).—The feet at the beginning of treatment

erythematous, scaly, desquamating, denuded, macerated, fissured, hyperkeratotic, vesicular and pustular. The meaning of these terms is clear with the possible exception of desquamating and denuded. In this study the former term was used to denote what the patient called "peeling"; the latter, that condition in which the upper layers of the skin had separated, leaving large raw areas.

The results of treatment were most striking in those cases in which the infection was particularly active and showed bullae and vesicles. In most instances subjective symptoms disappeared within twenty-four hours after the first treatment and the vesicles flattened out without rupturing. One of the first results in nearly all cases was a lessening of the moisture in the skin; this fact was commented on by most of the patients. The cuticle about the nails, any loose scales and the tops of the bullae or vesicles became blue with each treatment. This coloration frequently disclosed the presence of vesicles which might otherwise have gone unnoticed. Healing took place beneath the bluish crusts, which eventually were desquamated, leaving

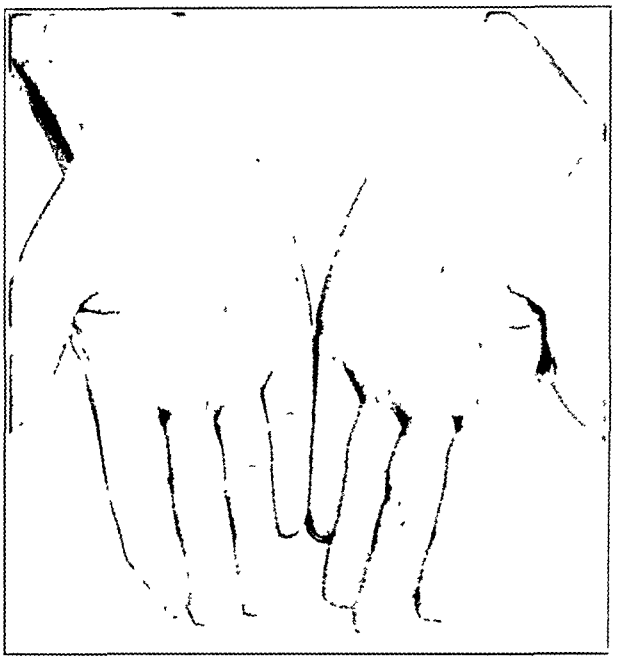

Fig. 5 (case 28).—The improvement of the hands

apparently normal skin. When the entire extremity showed dry, normal-appearing skin, the treatment was discontinued. Twenty-six, or 70 per cent, of the

Fig. 6 (case 28).—The improvement of the feet.

thirty-seven patients who were given treatment obtained a clinical cure; the remaining eleven are still under treatment.

The number of treatments necessary to attain a cure varied from four given over a period of two weeks

to eighteen given over a period of eight weeks. The average number of treatments was slightly more than six. Of the twenty-six patients discharged as cured, three have finished treatment so recently that follow-up has not been noted, but the other twenty-three have been followed for periods varying from three to six months. Of these, five suffered recurrences of some degree. Patients 1 and 7 reverted to a condition as severe as before treatment was started. Patients 6, 11 and 13 had mild recurrences.

Patient 28 gave a history of having had vesicles on his feet for twenty-five years. When first seen he had been walking with the aid of crutches for seven months and had been unable for the past few days to do even that because of blisters on his hands. The hands and one foot were literally covered with small thick-walled multilocular vesicles and large thin-walled pustules. Improvement was rapid and steady up to the point of almost complete clinical cure, when a relapse occurred; improvement followed further treatment. This has happened several times, but the patient is able to wear shoes, to walk without the aid of crutches and to follow his occupation. Patient 31, despite twenty treatments over a period of two months, has shown no improvement. Patient 34 has attained a clinical cure of the lesions on his feet (the lesions remaining healed for two and one-half months) but has persistent vesicles on his hands. Patient 35 has, in spite of fifteen treatments, considerable maceration in the fourth interspace of each foot. Patients 1, 10, 14, 22 and 29 presented, in addition to typical dermatophytosis, eczematoid lesions of the arms and legs. In three of these the eczematoid lesions disappeared while the feet were being treated. In the other two, 10 and 29, the lesions improved.

The data presented here are in the nature of a preliminary report. We have attempted so far to answer the question Does dermatophytosis of the hands and feet respond to iontophoretic administration of copper by the method described here? We find that in the majority of instances it does. The study has not, because of the demands of the patients, been extensively controlled. An attempt was made to treat only one foot when both were involved; in such cases only the treated foot responded. Saline solution used in both baths caused no improvement in the few cases in which it was tried. Similarly, soaking in copper sulfate solution without the application of current brought no relief.

We believe that the clinical cures obtained result from the action on the fungi of the copper driven through the skin by the electric current.

Summary of Cases

Patient	Duration	Degree	No. of Treatments Given	Length of Treatment, Weeks	Result	Recurrence or Reinfection	Clinical Type of Infection
1. M. B.	3 months	Moderate	10	4	Healed	Recurrence at 5 wks	Vesicles
2. J. C.	1 year	Severe	9	4	Healed	.. ....	Desquamation, maceration
3. D. C.	Few weeks	Moderate	16	8	Healed	No recurrence	Maceration, vesicles, erythema, scaling
4. R. F.	1 year	Moderate	4	2	Healed	No recurrence	Maceration, desquamation *
5. S. G.	Several years	Mild	11	7	Healed	No recurrence	Desquamation on feet, vesicles on hands
6. T. K.	4 months	Moderate	6	3	Healed	Fissures but no maceration	Maceration, desquamation
7. G. M.	6 months	Mild	8	4	Healed	Recurrence at 1 wk	Vesicles, maceration
8. J. P.	6 months	Mild	6	7	Healed	No recurrence	Maceration, fissures
9. O. R.	3 months	Moderate	10	7	Healed	No recurrence	Erythema, scaling, fissures
10. R. R.	Few weeks	Severe	9	7	Healed	No recurrence	Bullae and denuded areas
11. T. R.	2 years	Moderate	9	4	Healed	Recurrence at 1 mo	Maceration on feet, vesicles on hands
12. A. S.	Several years	Mild	7	4	Healed	No recurrence	Erythema, vesicles
13. P. S.	1 year	Mild	9	6	Healed	Mild recurrence	Vesicles
14. T. S.	3 months	Mild	6	2½	Healed	No recurrence	Maceration, vesicles
15. F. T.	2 months	Mild	13	6	Healed	No recurrence	Vesicles
16. D. W.	2½ years	Severe	8	5	Healed	No recurrence	Erythema, vesicles, desquamation
17. G. W.	Several years	Mild	6	4	Healed	No recurrence	Vesicles
18. J. W.	1½ years	Moderate	6	3½	Healed	No recurrence	Erythema, vesicles, scaling
19. S. N.	2 years	Moderate	7	3½	Healed	No recurrence	Maceration, desquamation
20. S. Y.	1 year	Mild	12	7	Healed	No recurrence	Erythema, scaling
21. B. S.	1 month	Severe	18	8	Healed	No recurrence	Bullae
22. L. H.	2 years	Severe	10	6	Healed	No recurrence	Erythema, vesicles
23. L. G.	1 year	Moderate	5	2	Healed	No recurrence	Vesicles
24. R. G.	1 year	Moderate	7	3½	Healed	.	Bullae
25. A. O.	2 months	Moderate	4	2	Healed	No recurrence	Bullae
26. G. Mc.	2 months	Moderate	6	3	Healed		
27. R. A.	18 months	Severe	4	4	Improved		Bullae, denudation
28. B. B.	25 years	Severe	10	14	Improved		Bullae, maceration, denudation, secondary infection
29. J. B.	Few weeks	Severe	7	4	Improved		Erythema, maceration, denudation
30. S. B.	5 years	Moderate	10	5	Improved		Vesicles, desquamation
31. R. C.	10 years	Severe	20	8	Poor		Vesicles and maceration on feet; eczematoid lesions and vesicles on hands
32. L. G.	Several years	Moderate	12	6	Improved		Vesicles, scaling, erythema on one palm only
33. A. M.	Few days	Severe	5	2	Improved		Maceration and denudation on feet; erythema, vesicles and fissures on hands
34. G. N.	1 year	Moderate	6	3	Feet healed; hands same		Vesicles on both feet and hands
35. J. T.	3 months	Moderate	15	7	Almost well		Maceration, fissures
36. H. W.	6 months	Moderate	11	8	Improved		Maceration between toes; erythema on dorsum of feet
37. J. P.	2 years	Moderate	12	12	Almost well		Eczematoid lesions

* Only one foot treated; other unchanged.

COCCIDIOIDAL OSTEOMYELITIS

PAUL E. McMASTER, M.D.
AND
CHARLES GILFILLAN, M.D.
LOS ANGELES

The surgical and pathologic aspects of bone and joint involvement in coccidioidal granuloma have received little attention in published articles. Twenty-four such cases have been studied and form the basis of this report. The condition is quite often misdiagnosed as either a pyogenic or a tuberculous lesion.

Wernicke[1] reported the first case of coccidioidal granuloma in 1892 from South America. Rixford and Thorne[2] reported two cases from California in 1894 and two years later Rixford and Gilchrist[3] gave a detailed report of these two cases and suggested the name Coccidioides immitis for the organism, which was later termed Oidium coccidioides and the disease coccidioidal granuloma by Ophuls[4] in 1905. The exact classification of the organism is still unsettled The North and South American strains of the disease have been presented by Jordon and Weidman.[5]

Numerous reports dealing with the condition to 1931 are listed by Carter[6] in a review of the subject and a discussion of the roentgenographic diagnosis.

GENERAL CONSIDERATION

The disease is caused by a specific fungus, Coccidioides immitis. The adult form of this organism in animal tissues is a spherule varying from 5 to 60 microns in diameter. It contains numerous endospores and has a doubly refractile capsule. The released endospores on rupture are capable of growing into adult spherules. These, if grown in culture mediums (Sabouraud's medium), will develop into mycelia. Hyphae of these undergo segmentation with the development of endospores, which may reproduce the organism either in mycelial form in culture or as spherules in animal tissues. Mycelia do not develop in animal tissues.

Although occurrences of the disease are occasionally reported in the eastern and midwestern sections of the United States,[7] a majority of the cases occur either in residents of California or people who have visited the state, and the San Joaquin Valley appears to be an endemic region. It is possible that cases occur and go unrecognized outside of California, being mistakenly diagnosed.

The organisms gain entrance to the body through the respiratory tract and the skin. Jacobson[8] considers that the mode of infection is by the bite of an insect. The disease has been produced in animals through the abraded skin by Ahlfeldt.[9] Gastrointestinal lesions are uncommon. Hence it is probable that this tract is not a frequent portal of entry. Transmission of the infection from patient to patient has not been established.

The dissemination is by blood and lymph streams and by direct extension. Multiple foci are more commonly seen in a patient than is a single focus. At autopsy it is not uncommon to find lungs, liver, spleen, meninges, subcutaneous tissue and bones involved.[10]

BONE AND JOINT INVOLVEMENT

Twenty-four patients with coccidioidal infections proved by demonstrating the organism either in culture or by microscopic section of bone and joint have been studied, of whom two were women and the others men. The average age of the patients was 32 years Thirteen of the twenty-four patients died, and each had an associated active pulmonary focus. Ten of these thirteen fatal cases showed multiple osseous lesions, while three presented only one demonstrable bony focus The eleven patients who survived were studied from a few months to seven years after discharge from the hospital, and only two of them had an infection of the lung; in both instances this was not marked and underwent healing. Five of the patients who survived had multiple bone or joint infections, while six had only a single lesion.

Fig 2.—Primary coccidioidal infection of the lower part of the humerus Bone destruction, some slight bony production, ossifying periostitis and evidence of joint invasion are present

There were four patients in the series younger than 20 years, of whom three survived.

Cutaneous infections, excluding those of draining sinuses overlying osseous infections, occurred as nodes or papules in six cases.

Owing to lack of space, this article is abbreviated here by the omission of several illustrations The complete article appears in the authors' reprints

10 A general and more detailed study of the disease is contained in the publication of Special Bulletin 57 by the California State Department of Public Health in 1931, which in turn is supplemented to July 1, 1936, by a special report in California and Western Medicine (**46**: 282 [April] 1937)

Practically all bones of the body excluding those of the face were involved in this series. Those most commonly affected were the tibia, vertebrae, sternum, tarsal bones, humerus, skull, fibula and radius.

Bone and joint infections are considered secondary to a primary infection at the portal of entry, such as

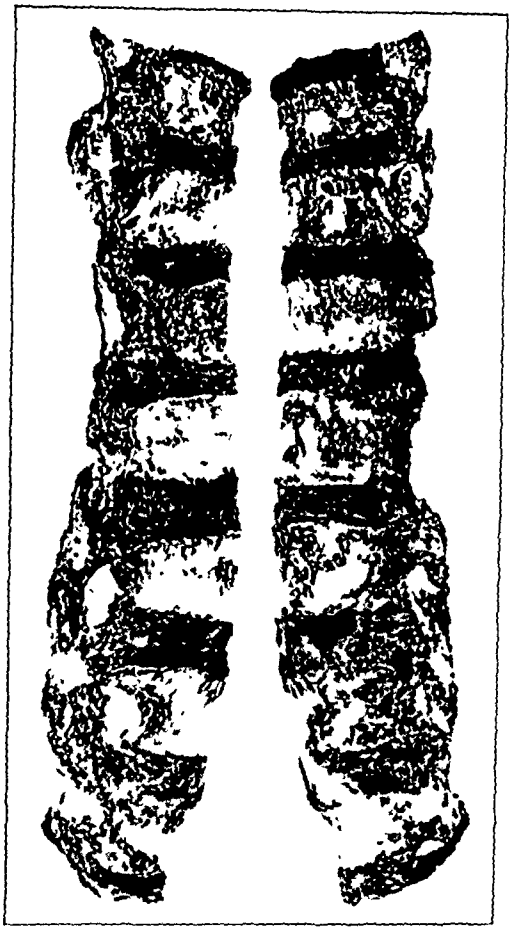

Fig. 4.—Gross specimen showing cavities of bone destruction, practically no collapse of the vertebral body and preservation of intervertebral cartilage. Large paravertebral abscesses were present.

the lung, mediastinal lymph nodes and skin, although as in tuberculosis of the bones and joints an active primary infection may not be demonstrable.

Four of the twenty-four cases studied exhibited primary localization in synovial membranes while the remainder were initially osseous in location. Some of the latter cases gave rise to joint infections by direct extension. Of the four cases of primary infection of the synovial membrane, one was of the ankle and secondarily invaded the ankle bones. Another was of the hip joint, giving rise to a spontaneous dislocation. The other two were of the knee joint.

Only four of the twenty-four cases occurred in children with open epiphysial lines. One of these four cases involved primarily a radial metaphysis while another occurred in a radial epiphysis. A third case exhibited initial localization in both a lower radial and a lower tibial epiphysis. The remaining infection was primary in the synovial membrane of the hip joint.

ROENTGENOGRAPHIC FEATURES

Almost all bones of the body excepting those of the face were involved in this series, and multiplicity of foci was common. The osseous lesions usually occurred in regions of cancellous bone either subperiosteal or central in the spongiosa. It is of interest that lesions in the long bones occurred near the ends. Shaft and medullary involvement was not noted except from direct extension. Short tubular bones, as the phalanges, exhibited what was interpreted as primary shaft lesions. The cancellous structure of vertebral bodies was the most common area of spinal involvement; however, cortical bone of the neural arches as well as spinous processes were in some cases initially infected. Flat bones, such as the sternum and the scapulae, showed destructive lesions usually associated with overlying soft tissue swellings. Primary localization occurred in both the metaphysis and the epiphysis.

Epiphysial cartilage, when present, offered no barrier to the spreading disease in some cases. Cortical bone overlying cancellous infections was at times destroyed from direct extension. Articular cartilage and cortex were invaded and destroyed by direct extension from a primary osseous lesion, while marginal erosion of these structures, which at times preceded ankylosis, occurred from primary infections of the synovial membrane.

The roentgenographic picture is somewhat dependent on the stage and virulence of the disease. Bony foci in the early and acute stages are primarily destructive, with hazy outlines, little if any surrounding bony production and usually no demonstrable periostitis.

Fig. 5.—End result of coccidioidal infection showing bony fusion between fifth and sixth cervical vertebral bodies as well as laminas and spinous processes. This patient was treated only by immobilization.

The more common chronic form of coccidioidal infection of bone exhibits a destructive type of lesion, with associated bone production and more often than not an overlying ossifying periostitis (figs. 1 and 2). Some of the osseous lesions will show an irregular margin with variable amounts of new bone formation. Others, however, will present a fairly sharply out-

lined wall about a cystlike cavity, being slightly suggestive of a bone cyst. At times these spaces may even show a tendency to trabeculation, giving a multilocular appearance.

Although epiphysial cartilage seems to offer no special barrier to the progress of the disease, interverte-

Fig. 7.—Bony ankylosis of tibio-astragalar joint following conservative treatment by immobilization in a plaster cast.

bral cartilage does not appear to be destroyed as early by coccidioidal granuloma as by a tuberculous infection (fig. 3). The vertebral body lesions tend to remain localized longer or to perforate through cortex forming paravertebral abscesses rather than destroying intervertebral cartilage, at least in the earlier stages. However, in the later stages of coccidioidal spondylitis, intervertebral cartilage is destroyed, which may lead to bony ankylosis if the patient survives (fig. 5).

Involvement of the skull occurs in both the outer and the inner tables and, as pointed out by Carter as well as by Abbott and Cutler,[11] presents small circumscribed punched out areas of destruction.

Carter mentioned that the disease has a special predilection for bony prominences such as the tibial tubercle, the malleoli, the condyles of the humerus, the olecranon and the styloid processes of the radius and ulna. These regions are not uncommonly involved in an essentially destructive lesion and if so are highly suggestive of coccidioidal infection (fig. 6).

The joints are both primarily and secondarily affected. In the former only the synovial membrane may be involved, in which case roentgenograms show only capsular thickening. However, a progression of this process will lead to marginal destruction simulating the changes seen in tuberculosis. A differential roentgenographic feature of coccidioidal arthritis compared to tuberculous arthritis is the less pronounced regional bony atrophy so characteristic of the latter. Joints are also secondarily invaded from adjacent bony infections, which are not halted in their spread by epiphysial or articular cartilage. The cartilage space of the joints is gradually narrowed, leading to bony ankylosis if the patient survives.

An ossifying periostitis overlying a bony focus is quite frequently present although not usually seen in the early stages (fig. 6). This feature is a diagnostic aid in differentiating a tuberculous infection in which an ossifying periostitis is infrequent, except in the rather rare tuberculous lesions of the shaft. The coccidioidal lesion is differentiated from chronic pyogenic osteomyelitis in which periosteal ossification occurs but in which there is usually much more sclerosis of cortical and cancellous bone than in coccidioidal lesions.

Infection of cancellous bone spreads by direct extension, usually causing erosion or destruction of overlying cortex. Rarely is cortical expansion seen. The process may progress directly through epiphysial cartilage and into the neighboring joints. Extension into the medulla or shaft occurs much less frequently.

Progressive healing of coccidioidal lesions by bony sclerosis is noted, as is healing of joint infections (fig. 7).

PATHOLOGIC CHANGES

The coccidioidal foci of bones of those patients who have died of the rather acute form of the disease show grossly necrosis and abscess. There is little if any evident production of tissue in the surrounding

Fig. 9.—Microscopic section (low power) showing coccidioidal granulation tissue producing lacunar absorption of bony trabeculae. Numerous giant cells of the foreign body and Langhans type are present.

bone. Cortex may be partially destroyed with an associated abscess of the soft tissue. Overlying periosteum may appear edematous and thickened or partially destroyed.

The osseous lesions of the chronic type of the disease reveal either an abscess or a cavity filled with

11. Abbott, K. H., and Cutler, O. I.: Chronic Coccidioidal Meningitis: Review of Literature and Report of Seven Cases, Arch. Path. **21**: 320 (March) 1936.

soft to firm granulation tissue or spongy bone with interstices filled with grayish granulation tissue (fig. 4). Bony "sand" is sometimes palpable in the regions of liquefaction necrosis. Occasionally larger sequestrums are seen. The surrounding bone may appear either hyperemic or irregularly sclerotic, and

Fig. 11.—Microscopic section (low power) of coccidioidal granulation tissue (ankle joint), showing marked similarity to tuberculous granulation tissue.

at times the region of destruction will appear cystic with varying degrees of bony sclerosis of the walls. The cortex overlying a cancellous lesion may be destroyed and an adjacent abscess in the soft tissue or a granulomatous mass noted. Adjacent to the region of cortical destruction a thickened periosteum is noted, which quite often will show ossification. These same periosteal reactions may be present overlying cancellous lesions, even though there is no apparent erosion of cortex.

Examination of infected joints shows a grayish thickened synovial membrane. Free fluid ranging from serous to seropurulent is also noted in some cases. Articular cartilage reveals marginal erosion by granulation tissue, which also usually involves articular cortex (fig. 8), and pannus may be seen. Segments of thinned articular cartilage may be separated from underlying cortex by hyperemic granulation tissue.

HISTOPATHOLOGIC CHANGES

Microscopic studies of the bony lesions in the acute form of the disease reveal necrosis and abscess, osteoclastic destruction of bone and very slight if any new bone formation. Coccidioidal spherules may be present.

The more common chronic bony lesions exhibit coccidioidal granulation tissue or abscess. The granulation tissue is composed of round cells, some polymorphonuclear leukocytes, histiocytes, vascular spaces, Langhans giant cells, occasionally typical "tubercle formation" and coccidioidal spherules. The latter either lie free in the stroma or are engulfed in a giant cell or lie in the center of a "tubercle." The spherules have a doubly refractile capsule and contain numerous small endospores. Trabeculae of bone, if adjacent to the granulation tissue, show as a rule serrated surfaces, and osteoclasts, more commonly of the mononuclear type but occasionally of the multinucleated type, occupy these lacunas (fig. 9). Partially or completely dead fragments of bone are seen. Some new bone formation from osteoblastic activity may be present.

Abscess or liquefaction necrosis shows a rather amorphous débris of cellular elements, serrated spicules of dead bone and coccidioidal spherules, some of which appear dead. The spherules are not present in all microscopic fields of either the granulation tissue (which may in some areas appear to be nonspecific) or abscess. The spherules should be searched for carefully, because if found they substantiate the diagnosis. If they are not found the diagnosis can be only presumptive.

The periosteal reaction shows usually only a nonspecific type of chronic inflammation and ossification.

Destruction of bone by coccidioidal granulation tissue appears to take place by osteoclastic activity, chiefly by mononuclear and to a lesser degree by multinuclear giant cells.

Cartilage is at times attacked and destroyed by the granulation tissue (fig. 10).

Coccidioidal synovitis, which may be either primary or secondary to a regional bony focus, shows thickening of the membrane, infiltrations of round cells, plasma cells and some polymorphonuclears, histiocytes, coccidioidal spherules and typical Langhans giant cells. The appearance may be strikingly similar to tuberculosis, necessitating a search for the diagnostic spherules (fig. 11). A spherule may be either loose in the stroma or engulfed in a Langhans giant cell (fig. 12) or present

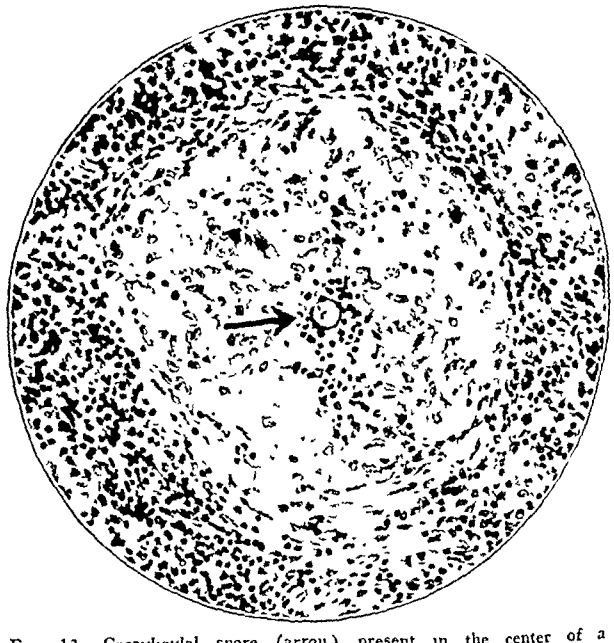

Fig. 13.—Coccidioidal spore (arrow) present in the center of a "tubercle."

in the center of a "tubercle" (fig. 13). Marginal erosion of articular cartilage and cortex occurs by direct extension from the infection of the synovial membrane. Subchondral invasion of granulation tissue, usually of a nonspecific nature tending to separate cartilage from underlying bone, may occur. The articular cartilage becomes thinned by action of the granulation tissue.

Pannus is usually present and may be either of a nonspecific nature or quite amorphous.

Microscopic evidence suggests that both bone and cartilage are destroyed by direct cellular activity of the granulation tissue. It is further assumed from microscopic studies that the coccidioidal pus has no direct destructive action on either bone or cartilage.

TREATMENT

The treatment of coccidioidal infections of bones and joints is of a general as well as of a local nature. If the patient has an associated active pulmonary lesion, this must receive special attention, for all such patients in our series died except two who had minimal pulmonary foci. General supportive measures as well as rest and immobilization of the involved bone or joint lesion are indicated. The latter measures are requisite to prevent metastatic spread of the disease, especially since the disease has a tendency to multiplicity of foci.

The question arises whether conservative or surgical procedures should be instituted in the handling of bone and joint lesions. There are cases in which involved parts have been immobilized with plaster of paris casts that have resulted in improvement and even apparent cures. This is probably the treatment of choice in the acute and severe general infections in which the patient is too ill to stand surgery.

Chronic infections in which bone abscesses are present should be treated by surgical drainage with saucerization of the area by removing the surrounding infected bone. The cavity is packed loosely with petrolatum gauze to allow for granulation from the bottom and the part immobilized in plaster of paris casts after the method of Orr.

Cures of infected joints appear to result only from ankylosis; hence treatment should be directed to this end. Prolonged immobilization of the infected part in casts in addition to general supportive treatment may accomplish this end if the patient does not succumb to the disease process during the interval. Operative arthrodesis in chronic joint infections, as for tuberculosis, seems indicated, with subsequent immobilization until ankylosis occurs. This applies to spinal as well as to peripheral joint lesions.

Amputations were performed in three cases, one of which was for an infected large toe and two were for diseased ankles. All three patients survived but none had active lung lesions. Since the mortality is rather high in this disease and the chance of multiple foci developing is common, removal of a peripheral, well advanced bone or joint infection by amputation should be considered and is at times indicated. This treatment should also be considered, even in cases in which there are associated pulmonary lesions, excepting perhaps the florid acute ones, for with amputation of a major peripheral infection the patient should have a better chance of overcoming the general toxemic effects of the disease.

In cases presenting multiple bone and joint lesions the treatment will depend on whether or not there is an active pulmonary lesion, which again, if present, must receive initial and vigorous attention. Conservative or surgical measures for the peripheral lesions will be determined by how far advanced the process is and by the general condition of the patient.

In addition to either conservative or surgical procedures in the treatment of bone and joint infections, whether single or multiple, general supportive measures and usually absolute bed rest are necessary. There appears to be no specific medication, although colloidal copper, antimony and potassium tartrate and iodides have been given with variable success. Jacobson has recently made and used a coccidioidal vaccine with which he claims to have had good success.

DIAPHRAGMATIC FLUTTER WITH SYMPTOMS SUGGESTING ANGINA PECTORIS

RICHARD W. WHITEHEAD, M.D.
CLOUGH T. BURNETT, M.D.
DENVER
AND
JOHN B. LAGEN, M.D.
SAN FRANCISCO

A clinical syndrome of diaphragmatic flutter with symptoms of angina pectoris occurring in a man of 57 was described under the foregoing title, in THE JOURNAL by Dr. W. B. Porter [1] of Richmond, Va., about two months before the same patient was admitted to the Colorado General Hospital under another name. Dr. Porter described the patient as a "deep sea diver."

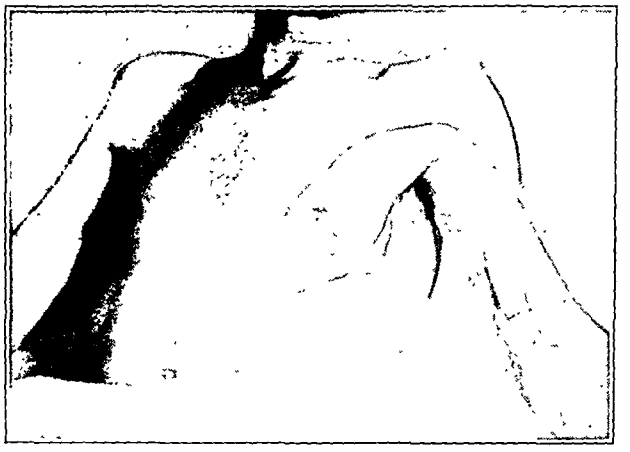

Fig. 1.—Distribution of pain.

To us he stated that he was a "trapper" from the high mountains and that he had been living and working as a trapper near Berthoud Pass—an average elevation of 13,800 feet above sea level. This report will serve as supplementary to that of Dr. Porter, presenting certain similarities, certain additional complaints and certain discrepancies. A telegram under date of Jan. 29, 1937, from Dr. William J. Kerr of San Francisco indicated that the same patient was in the Hospital of the University of California. A supplementary report from that institution is appended.

The patient was brought to the hospital May 20, 1936, in a police ambulance. At the time of entrance he complained of

From the Departments of Physiology and Pharmacology and Medicine, University of Colorado School of Medicine. With a supplementary report by John B. Lagen, M.D., Department of Medicine, University of California.

Dr. O. Leonard Huddleston of the Department of Physiology and Pharmacology made the oscillograph records. Dr. Bernard Grossman made many clinical observations. Miss Margaret Burnett, medical social worker, made the social studies.

1. Porter, W. B.: Diaphragmatic Flutter with Symptoms of Angina Pectoris, J. A. M. A. **106**: 992 (March 21) 1936.

extremely severe anginal pains over the precordium. These pains were said to extend up into the neck on the left side and down the inside of the left arm, and there was a tingling sensation in the last two fingers on the left hand. Frequently during this and subsequent attacks the patient complained of a cramping sensation in the second, third and fourth fingers of the left hand and there appeared to be spasm in these digits. In figure 1 is shown the pain distribution noted in this patient, which is quite typical of that observed in certain cases of

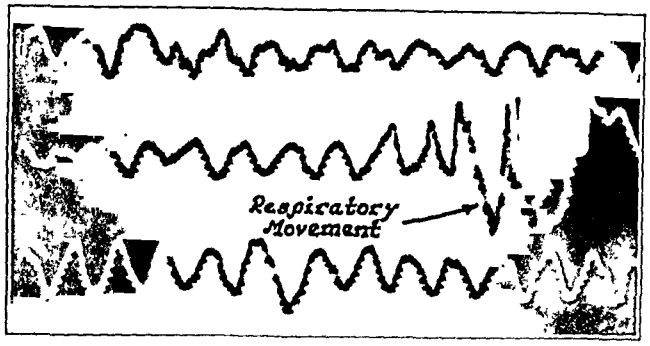

Fig. 2.—Sound record of extraneous respiratory sounds recorded from right base anterolaterally May 25, 11:15 a. m.

angina pectoris. He was breathing very slowly at the time of entrance. He stated that he had come down from the mountains and had a sudden attack of pain, following which he became unconscious. He described the pain as a "blocking of the heart." The family history, as stated, was essentially negative. The patient claimed that he had always been a miner and trapper and that he had worked in hard rock mines up until about ten years ago, at which time he was told that he had pneumoconiosis. He stated that he had left the mines at that time. The past history revealed that he was shot through the jaw at one time. He had malaria when a boy. He gave a history of having had ticks removed recently. The present illness began May 20, 1936, at about 7 p. m., as already described.

On physical examination the patient was sitting in bed in apparently extreme pain. The mouth was edentulous and the tonsils were injected. The chest was symmetrical and the expirations were equal and regular but diminished. The lungs were resonant to percussion; no rales or pleural rubs were heard. The heart was normal, the rate 64 and regular. Some tenderness was elicited at the left pectoral border in the fourth intercostal space. The blood pressure was 110 systolic, 80 diastolic. Abdominal examination was negative. There was no cervical or axillary adenopathy. There was a white linear scar at the hair line above the right forehead. The reflexes were physiologic.

One of us (C. T. B.) saw the patient May 21 in an attack of severe pain. The patient pounded the left side of the chest with his fist and in general manifested more theatricals than seemed consistent with an anginal attack. On auscultation a very peculiar sound was heard over the entire chest. This can best be described as a tick-tock with a 3 to 1 or 4 to 1 ratio to the heart beat. This tick-tock sound was of unequal intensity throughout the chest, being louder toward the lung bases. The patient breathed rather irregularly with periods of apnea. A regular, rapid, oscillating movement of the entire thorax was thought to have been seen by some, not confirmed by others. An electrocardiogram was taken at this time which showed a heart rate of about 60 per minute with a normal curve. Several subsequent electrocardiograms were normal. The patient was given amyl nitrite, which did not relieve the symptoms. He was then given one-fourth grain (0.016 Gm.) of morphine but continued to have attacks of pain throughout the day. A chest plate was negative. Barium sulfate showed nothing in the esophagus nor any obstruction or spasm. May 23, under the fluoroscope, it was found that both diaphragms were moving up and down rapidly and regularly and that this rapid motion was synchronous with the sounds previously described, and a diagnosis of diaphragmatic flutter was made. This was confirmed May 26, although the condition was not so pronounced at that time. The rectal temperature ranged from 99 to 103.8 F. (with the exception of two periods of hyperpyrexia to be mentioned later) with wide daily variations, but the pulse was above 100 only on one observation and it averaged from 50 to 64.

Laboratory examinations were unusual only in that the hemoglobin was 15 Gm. and the red cell count was 4,290,000, a finding not consistent with continued residence at an altitude of over 12,000 feet. The white cell count was not significant. The sedimentation rate at one-half hour was 6 per cent, at one hour 15 per cent. The blood Wassermann reaction was negative. A blood culture was negative. Agglutination was negative for B. proteus and the paratyphoid bacillus. The spinal fluid pressure was 325 mm., the cell count 2 small lymphocytes. A section of a portion of the left sternocleidomastoid failed to show trichinae.

During the succeeding days he complained of pain in varying degrees for which he was given opiates. During none of the attacks was there any color change or evidence of circulatory disturbance of any type. When opiates were denied him he became irascible and demanded release. In spite of objective evidence of diaphragmatic flutter it was evident that this did not explain the entire clinical picture and from this time on he was largely controlled with barbiturates.

An attempt was made to control the flutter with carbon dioxide and oxygen inhalation: 10 per cent carbon dioxide with 90 per cent oxygen was employed. Without carbon dioxide the oscillatory movement was 140 and the heart rate 64; with carbon dioxide, after one minute, the heart rate was 69 and the respiration regular. After the patient had received carbon dioxide and oxygen for about four minutes he reverted back to the former type of oscillatory respiration. Subsequent observations showed that the spasmodic movements were inconstant and suggest that the apparent effect of carbon dioxide and oxygen may have been coincidental. Later the left phrenic nerve was injected with 2 per cent solution of procaine hydrochloride. This caused very severe pain for about one minute, after which all the patient's pain was entirely relieved, the tick-tock sound stopped, and the breathing became normal and regular. For two days he did not complain of pain and there was no evidence of flutter. On the second morning after the procaine injection he was presented in the clinical amphitheater before a group of students. While there he sneezed and the flutter returned, at which time a bilateral flickering motion was easily seen and felt over the lower five intercostal spaces. Another possible etiologic factor in this attack may have been

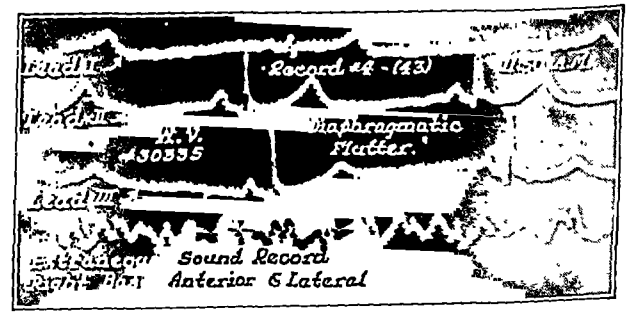

Fig. 3.—Electrocardiogram and sound record of extraneous respiratory sounds.

irritation at a remark of one of us to the effect that he was not very cooperative, since he was being presented in the hope that the flutter could be demonstrated. During this attack and during many subsequent attacks the flutter was transient, appearing at intervals of approximately forty seconds and lasting from four to seven seconds. Kymograph records to be discussed later were taken at this time. Recurring pain and flutter prompted reinjection of the left phrenic nerve. This gave relief for only a few hours. Injection of the right phrenic nerve likewise led to only temporary cessation of flutter and pain.

June 3 under sodium amytal and local anesthesia a left phrenicotomy was done followed by immediate cessation of the flutter. Resection was not attempted because of possible permanent effects.

The following day at 4 a. m. the temperature was reported as 112 F. This was checked by rectum, mouth and axilla with a nurse and a physician constantly in the room. At 8 a. m. the rectal temperature was 102 F. On the following day at 8 p. m. a temperature of 109.8 F. was observed. On this occasion especial precautions as to accurate thermometers and care that there should be no opportunity for malingering were observed. Several physicians and nurses were constantly with the patient at this time. If there was malingering it could not be demonstrated. To exclude a brain lesion as a cause for this hyperpyrexia, a roentgenogram of the skull was taken and showed no evidence of a pathologic condition. Later a request for an encephalogram to rule out further any brain disorder was refused.

About twenty-four hours after the left phrenicotomy, pain and flutter recurred, the flutter being visible throughout the entire chest at a rate of 100 per minute. Two days later the right phrenic nerve was crushed but no resection was attempted. This was followed by cessation of flutter for three days, when he again complained of violent pain. Flutter was not demonstrable as previously but, because of lack of cooperation on the part of the patient, fluoroscopy or kymographic tracings were not attempted; but it was believed that transient flutter was present.

Records of the adventitious respiratory sounds heard over the chest were made on several occasions by means of a cathode ray oscillograph and microphone. The first record (fig. 2) shows the character of the waves obtained on placing the microphone over the right base, anterolaterally. The records were taken successively. In the second record one sees how the sound record is modified by a respiratory movement. The other more regular waves were produced by the flutter of the diaphragm and possibly also the intercostals.

Figure 3 shows the three leads of the electrocardiogram, taken successively. These records show essentially a normal electrocardiogram. The lowest tracing is a record of the extraneous sounds taken from the right base, anterolaterally. It may be seen that these have a more rapid rate than the heart and could therefore not be circulatory in origin, since the rate of the extraneous sounds was about 200 per minute and the pulse rate was 74 per minute.

Figure 4 shows sound records made by placing the microphone over the mitral and tricuspid areas. Two places are marked where a heart tone could be identified. The other waves were produced by the flutter of the diaphragm and possibly also by the intercostals. The lowest curve of the record was obtained by placing the microphone over the right base at the anterior axillary line. The rate of flutter at this time was about 180 per minute.

Figure 5 is from a kymograph record obtained by placing a blood pressure cuff over the lower part of the thorax and fastening it on with a bandage. The bag was then slightly inflated and the rubber tube leading from the bag was connected to a tambour. The writing point of this was made to write on a revolving smoked drum. This record was made in the afternoon of the day on which procaine was injected in the region of the left phrenic nerve. The record shows considerable irregularity in the respiration, but the rate is too slow for "flutter." There is a tendency for the respiration to be Cheyne-Stokes in type during sleep (induced by barbiturate).

COMMENT

Much difference of opinion exists concerning the innervation of the diaphragm. Recently Strauss [2] studied the distribution of the phrenic nerves to the diaphragm in numerous animals and in man. He found a great deal of similarity in distribution in the different species. Fibers from one phrenic nerve were never observed to supply the opposite half of the diaphragm. The intercostals were never found to supply the diaphragm in any of the mammals studied or in man. He concluded that, with the exception of birds, all the animals studied possess the phrenic nerve as the only motor nerve to the diaphragm. Observations here and at California would suggest that in this patient either an accessory phrenic nerve supply existed or that a portion of the flutter may have been due to clonic contractions of the lower intercostals.

Besides the diaphragmatic flutter observed in this patient, the next most remarkable and puzzling symptom was the transient hyperpyrexia.[3] In considering the cause of the high fever we thought that hypothalamic involvement should be considered, but nothing in our

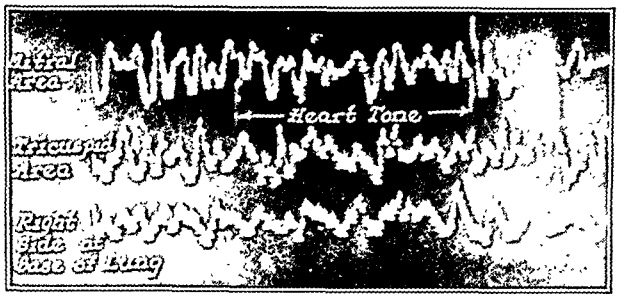

Fig. 4.—Adventitious respiratory sounds and heart tones, May 25, 11:40 a. m.

studies confirmed this idea. However, certain clinical and experimental observations [4] indicate that extreme degrees of alteration in the temperature control may result from lesions in the hypothalamus. A further important observation in this case may be correlated with work of an experimental nature involving the hypothalamus. It has been shown in animals that a state of "sham" rage occurs following the production of lesions in the hypothalamic region.[5] In animals so operated on, slight disturbances, such as by moving or by making noises in the vicinity, lead to all the manifestations of rage. It has been noted previously that our patient was very irascible and certain attacks of flutter appeared to be associated with emotional upsets. We regard it as distinctly possible that the emotional upsets and the hyperpyrexia may point to a lesion of the midbrain in this man. For confirmation of this of course a pathologic examination of the midbrain would be required. In retrospect, we regret that we did not perform tests designed to determine the stability of the vasomotor control, such as the response of the blood pressure to exposure to cold.[6] Likewise cutaneous temperature observations would have been valuable.

The ultimate diagnosis arrived at in this case as one of hysteria in a psychopathic inferior individual seems justified and was made only after numerous clinical consultations had failed to reveal the existence of a

demonstrable neurologic lesion. The diagnosis of hysteria seems to fit in well with the transient nature of the diaphragmatic flutter and the fact that the temperature would reach such extreme degrees at times. It is not uncommon for hysteria to be associated with hyperpyrexia, and the literature contains reports of alterations of diaphragmatic function in this disorder.[7] Other functional nervous system disorders, such as epilepsy, may be associated with modifications in the contractions of the diaphragm.

This case is of further interest from the diagnostic standpoint. At first sight the patient presented somewhat typical symptoms of angina pectoris, which condition was definitely ruled out by clinical, electrocardiographic and fluoroscopic observations.

A point of some social interest is the conflicting statements made by the patient regarding his past history. A rather extensive inquiry established the fact that he had been treated in various hospitals, in several states and under different names, but for the same clinical syndrome. Data and fingerprints submitted to the U. S. Department of Justice resulted in a report from this department that the patient had already been traced to four different localities under four different names. He subsequently was admitted to Dr. Kerr's service in San Francisco under a sixth name. In these days, in which the cost of indigent medical care is being given much thought, it would be interesting to know what was the combined costs of care in the more than seven institutions which had received this patient within the period of about one year. If to this figure is added the estimated cost of the services of the various physicians who served gratuitously, there would seem to be some argument in favor of some form of registration of our transient population.

SUMMARY OF REPORT SUBMITTED FROM SERVICE OF DR. WILLIAM J. KERR, UNIVERSITY OF CALIFORNIA HOSPITAL, BY DR. JOHN B. LAGEN

This patient[8] was admitted to the hospital Jan. 28, 1937, under the name of Thomas Dawson, aged 67. The complaint was severe precordial pain of eight months' duration. He claimed perfect health until May 1936, when in his duties as a Texas deputy sheriff while chasing a bandit he was suddenly stricken with severe pain over the heart. The type of pain and its radiation were essentially as previously stated. He described his care in the University of Colorado Hospital and admitted great relief from pain and stated that he had returned to his duties as deputy sheriff, being troubled only by dyspnea. At the end of this time while again "bandit chasing" he had a recurrence of the pain. (Records show that he was hospitalized twice elsewhere for the same complaint.) All observers in many conferences noted that it was difficult to keep him from "chasing bandits" and make him stick to facts.

CLINICAL OBSERVATIONS[9]

Healed supraclavicular fossae phrenicectomy scars were observed. The peculiar sound was heard over the lower part of the chest, especially on the left. It was described as a rather loud, swishing, churning sound with a regular rhythm, independent of the heart sound, with a rate of approximately 240 per minute.

The area of hyperesthesia was identical with that previously described.

A lead 4 electrocardiogram showed faint superimposed diaphragmatic flutter waves.

OPERATION AND RESULT

Feb. 4, 1937, the left phrenic nerve was exposed under local anesthesia. The incision was made across the previous operative scar, and beneath the clavicular head of the sternomastoid muscle was found a resistant mass of scarred areolar tissue and muscular fascia. Beneath this the nerve was found in its usual position traversing the scalenus and was normal in appearance except for a small scarred area at one point in the nerve

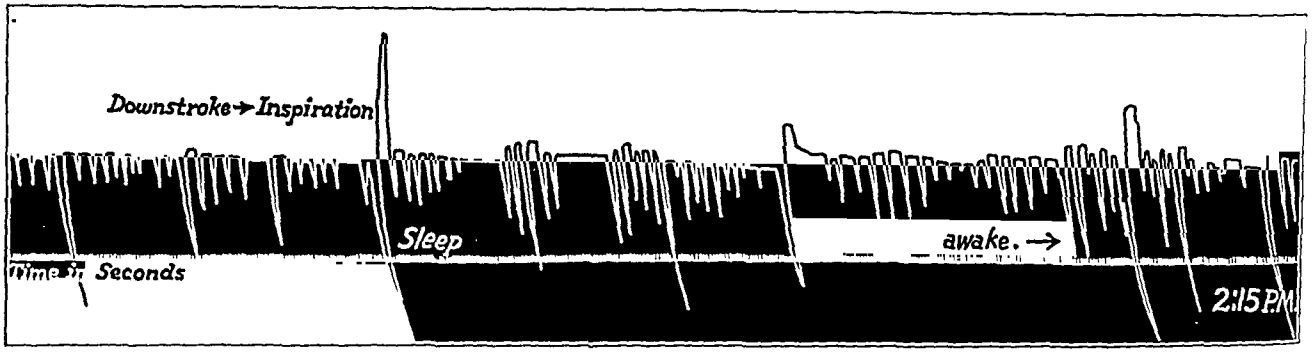

FIG. 5.—Respiration record, May 26, 10:45 a. m., after left phrenic nerve was injected with procaine hydrochloride.

sheath. The phrenic nerve was then retracted on two silk ligatures and a weak faradic current was applied directly to the nerve trunk by means of the usual electrode. During the course of the operation to this point the patient had been complaining bitterly of discomfort in general and his usual chest pain in particular. He was difficult to restrain and kept demanding that the operation, to which he had willingly agreed, now be immediately discontinued. The respirations were slow and of the deep, gasping type; the diaphragmatic flutter was audible as before.

On the application of the faradic stimulus the patient uttered a sharp cry, gave a jerk, twisted onto his right side in spite of restraint and then vomited.

In a minute or two he relaxed and there was a remarkable improvement in his demeanor. He stated that immediately following the electrical shock, which he felt travel down to his abdomen, there was complete cessation of his chest pain and discomfort. No flutter sounds could be heard on auscultation of the chest or abdomen. The patient was now moved to the x-ray department, and fluoroscopy revealed a slight paradoxical motion of the left leaf of the diaphragm with respiration. Flutter was not visible. There was a weak, undulating flutter through the right leaf of the diaphragm. Under the fluoroscope, faradic stimulation was again applied to the exposed left phrenic nerve, which caused a sharp, downward descent of the left leaf of the diaphragm. The patient was returned to the surgery, where the left phrenic nerve was infiltrated with procaine and avulsed, about 31 cm. being obtained.

7. Gill, W. Gordon, and McArdle, M. J.: Two Cases of Pseudo-Tympanites Caused by Hysterical Spasm of the Diaphragm, Guy's Hosp. Rep. 84:94 (Jan.) 1934.

8. Photographic comparisons prove the identity of the patient.

9. Clinical and laboratory observations made in California are given which are at variance with the preceding report. In addition, certain observations are included for emphasis.

The usual skin closure was made. The patient returned to the ward in good condition.

After the operation the patient had no further attacks of precordial pain; his respirations were normal in character with a rate of 20 per minute and no flutter sounds could be heard over the chest. The alteration in his general behavior was striking. He became alert, pleasant and cooperative. However, if too closely questioned concerning his past he still took refuge in fanciful stories.

All temperature observations were rectal. The preoperative temperatures reached daily from 100.8 to 104.3 F. Postoperative temperatures of 107, 103.8 and 102.9 F. were observed, not accompanied by proportional pulse or respiratory rate increase. At first these were not considered due to malingering but subsequently it was the opinion of the California observers that these temperature elevations were due to malingering.

The electrocardiogram after operation showed slightly improved R wave voltage and no diaphragmatic flutter waves. Chest fluoroscopy showed the left diaphragm immobile, high and relaxed, the right normal and without any evidence of flutter.

On the twelfth postoperative day the patient awakened at 2 a. m. complaining of typical precordial pain with left arm distribution. No flutter sound was audible. Because of pain he claimed inability to use the muscles of the left arm; by midafternoon he presented the picture of a left-sided hemiplegia involving the arm and leg but with the neurologic observations of malingering. On the following day he was seen to use both arm and leg when unconscious of observation. On the thirteenth postoperative day he again complained of severe precordial pain, also extending over the right lower part of the chest anteriorly. At this time the flutter-murmur was heard over the right lower part of the chest anteriorly and posteriorly and fluoroscopy revealed flutter of the right diaphragm.

Temporary relief from flutter was obtained by faradic stimulation over the right phrenic nerve through the skin, and response to carbon dioxide inhalations was as in the Denver observations. Avertin with amylene hydrate anesthesia also caused cessation of the flutter.

February 25, under local anesthesia, the right phrenic nerve was exposed through the previous scar. Beneath the area of the old scar were found remnants of a previously crushed phrenic nerve which were frayed out, separated and presented themselves as fine filaments scattered throughout the scar tissue. Only two fibers of the nerve could be definitely isolated, and these were sectioned. No specimens were taken. The patient was returned to the ward in good condition.

Just before the patient was taken to surgery, no flutter sounds could be heard over the right side of the chest. After return from surgery, repeated auscultation revealed no evidence of flutter. By February 28 the patient had become so unruly and so difficult to manage that he was permitted to sign a release slip and leave the hospital. On discharge of the patient there was no evidence of diaphragmatic flutter or of hemiplegia of the left side. The patient ostensibly left for Los Angeles, still having in his pocket an unused bus ticket for that destination.

March 6, 1937, a letter was received from the Ventura County Hospital stating that a patient named Timothy Dawson was admitted on the evening of March 3 complaining of severe pain over his heart and severe dyspnea. He stated that he had been in the University of California Hospital, where an operation was done. The patient had been found lying beside the road near Piru, Calif. At the time of entry the patient was found to have a recurrence of his diaphragmatic flutter. He was given morphine and felt quite well by the next morning. He remained five days in the hospital without recurrence of the flutter, then signed a release and left. One day later he was again brought in, this time with what was apparently a hysterical hemiplegia, which cleared rapidly. Ventura County Hospital authorities further stated that their social service department discovered that the correct name of the patient was Walter Urwiler and verified his residence in Tucson, Ariz. He was sent to Tucson on the train, March 11, 1937.

FRACTURE OF THE SHAFT OF THE ULNA

WITH DISLOCATION OF THE HEAD OF THE RADIUS

GEORGE HALSEY HUNT, M.D.
Passed Assistant Surgeon, U. S. Public Health Service
SEATTLE, WASH.

When the ulna is fractured, what happens to the radius? Usually it is fractured also, but if not, what then? Almost invariably in the case of indirect violence, and frequently in the case of direct violence, if the radius is not fractured, the radial head is dislocated. Unless one is specifically looking for it (and particularly if the elbow joint is not included in the roentgenogram) a dislocated radial head can easily be overlooked until the patient's continuing disability two or three months later forces a readjustment of the surgeon's complacency that "only the ulna was fractured."

Fig. 1 (case 1).—Right elbow before reduction. The dislocation of the radial head can be clearly seen.

The dislocation of the radial head is overlooked largely because most physicians have not been trained to look for it. The ulnar fracture is frequently 3 or 4 inches (7.6 or 10 cm.) below the elbow; attention is immediately centered on the obvious lesion, and unless one's first reaction on seeing a fracture of the ulna is to find something amiss with the radius a dislocated radial head may or may not be discovered. Careful physical examination will usually discover the true situation, as the radial head is almost always palpable anterior to the lower end of the humerus, with a hollow over its normal location. Rotation of the forearm is painful and usually greatly limited.

For some reason, this combination of fractured ulna and dislocated radial head has not been stressed in the American literature, though it has been recognized for over a century. Two cases were reported by Monteggia in 1814, and almost a hundred years later Perrin [1] honored this early report by suggesting that the condition be called "Monteggia's fracture." This term is today universally used in the Continental literature. Possibly as a result of the long-distance collaboration

Published by permission of the Surgeon General, U. S. Public Health Service.

1. Perrin, Jules: Les fractures de cubitus accompagnées de luxation de l'extrémité supérieure du radius, Thèse de Paris, Paris, G. Steinheil, 1909.

of these two Europeans, the subject is referred to rather frequently in the Continental journals, while its neglect west of the English Channel continues. During the four years 1934-1937, there was only one article in

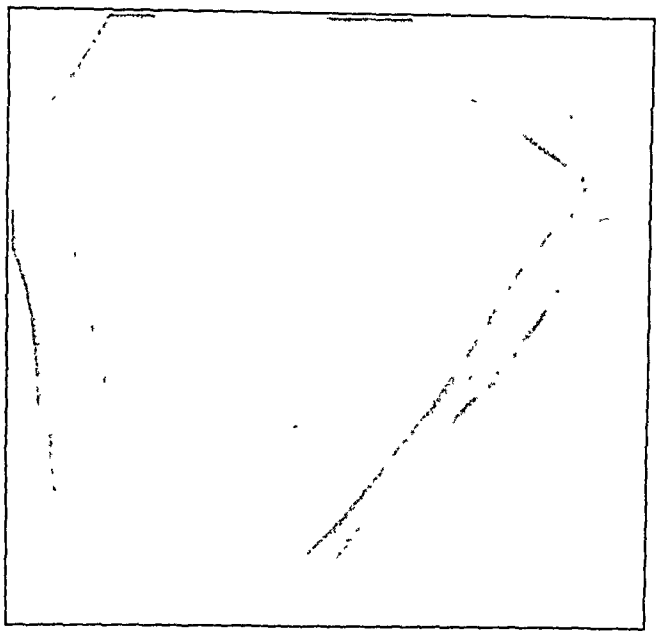

Fig. 2 (case 1).—Right elbow three and one half weeks after reduction. The radial head remains reduced and there is visible healing of the ulnar fracture.

English on the subject listed in the *Quarterly Cumulative Index Medicus*, four pages by Cunningham,[2] while foreign language journals published twelve articles, one of them thirty-eight pages long.

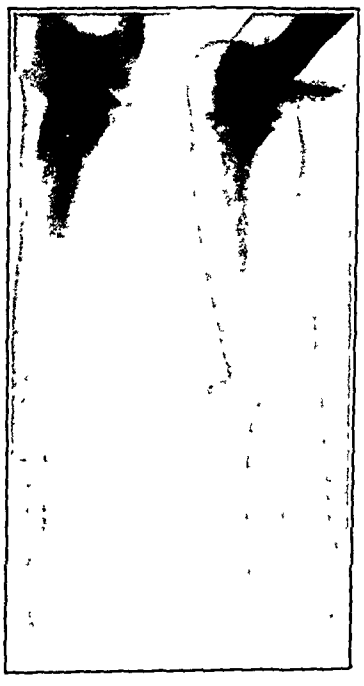

Fig. 3 (case 2).—Left elbow before reduction.

The textbooks of Speed [3] and Wilson and Cochrane [4] mention the lesion and discuss it briefly. My paper, however, is primarily addressed to the general practitioners, who see most of these cases first, for unless the condition is stressed more than it has been in the past a goodly percentage will continue to be missed. As Cunningham concludes, "neglected cases result in great loss of function and much deformity."

The cases are not as rare as their literary neglect would lead one to believe. Cunningham[2] had fourteen cases in a series of 257 consecutive fractures of the ulna, excluding fractures of the olecranon and styloid process. In other words, more than 5.4 per cent of all his fractures of the shaft of the ulna were accompanied by dislocation of the radial head.

Granted that an orthopedic or fracture specialist wil have a higher percentage of complicated cases, the fac remains that this particular injury is common enough to warrant more attention than it has had. O the cases reported in this paper, the first two were admitted to a 200 bed general hospital within six days of each other.

It may be in order to review briefly the reasons why fracture of the ulna by indirect violence is almost always accompanied by some injury to the radius. The basic reason is that the radius and ulna form mutual splints each bound to the other at top and bottom by strong ligaments and attached almost throughout their full lengths by the strong interosseous membrane. As a consequence, it is difficult for any indirect violence to put enough stress on one of the members of this team to fracture it without previously or simultaneously blocking the other member out of the play. Usually, of course, there is no subtlety about the matter—both bones are broken—but occasionally the splinting and strengthening power of the radius is circumvented by the neat trick of knocking out the supporting prop. With the elbow in full extension, a sudden thrust upward through the radius tends to force it forward off the capitellum, and if the force is strong enough it will sometimes rupture the annular or orbicular ligament that surrounds the radial head and binds it to the ulna, thus allowing the head to slip forward and upward while its ulnar fellow is being fractured.

Fig. 4 (case 2).—Left elbow on Nov. 27, 1935, three months after reduction. Radial head in normal position. Very slight healing of the ulna.

For all practical purposes, injury to the ulna by indirect violence means injury to the radius also. Recognition of this not uncommon combined lesion is the sine qua non of its treatment, and its recognition often depends largely or entirely on the instinctive asking of the question "what is wrong with the other bone?"

In the case of direct violence, it is of course possible to fracture either radius or ulna without grossly damaging the other, but here, too, Monteggia's lesion must be kept in mind for, according to both Cunningham [2] and Wilson and Cochrane,[4] the commonest cause of the injury is a direct blow against the extensor surface of the forearm near the junction of the middle and upper thirds of the ulna. In this type of injury, the force first fractures the prominent ulna and then, if strong enough, carries forward against the radius, whereupon a triangular battle develops among the force, the bone and the annular ligament. The ligament fre-

quently proves weakest, tears and allows the head of the radius to slip forward and upward. A similar but reversed injury, with posterior dislocation of the radial head, has been reported but is rare.[5]

Once one's attention has been drawn to the region of the elbow, there is seldom any difficulty in recognizing the dislocation of the radial head. It is perfectly obvious if only one looks for it. It may be thought that in children with cartilaginous epiphyses, in whom these injuries occasionally occur, the lack of shadow at the upper end of the radius might offer serious diagnostic difficulty, but solution of this problem is simple if one keeps in mind the fact that the undamaged radius, no matter how little it may be ossified, will always point directly at the capitellum. Roentgenograms in two planes, therefore, will give the answer. If the radial diaphysis points toward the capitellum in both pictures, well and good; but if in either one of them it is pointing somewhere else than directly at the capitellum the epiphysis of the radial head is either dislocated or separated. This point is illustrated in case 1, in which the difference between the prereduction and postreduction appearance of the upper end of the radius is clearly seen (figs. 1 and 2).

Once the diagnosis has been made, what of treatment? These may be difficult fractures to treat, and the best orthopedic or fracture specialist available may well be consulted at the beginning rather than after several weeks of unavailing puttering. The difficulty is twofold: first, that closed reduction of the dislocated radial head involves insinuating it into place between the torn ends of the ruptured annular ligament and, second, that if the radius is reduced the forearm is restored to its normal length, whereupon it becomes something of an expert's job to get the ends of the ulna into apposition so that healing rather than nonunion will result. The first consideration, that is, reduction of the dislocated radial head, is often impossible without an open operation, and even if closed reduction is apparently obtained the forearm should be cautiously extended after from ten to fourteen days to see whether reduction is real or illusory. If the latter, the radial head will pop forward as soon as the forearm is extended, which means open operation, and the sooner the better. It is easy to see that an attempt to reduce the radial head might easily (and usually does) simply push the head back against the annular ligament, whereas for restoration of normal function the head must be encircled by the ligament.

If operation becomes necessary, the radial head should be replaced in its normal position and the torn ends of the annular ligament sutured together over it. Speed[3] suggests that "early operation with resection of the head in adults gives fairly satisfactory results," but this operation is probably indicated only if anatomic replacement is impossible.

As to the possibility of ulnar nonunion, nothing hard and fast can be laid down. The ulna is a notorious site of nonunion and many cases of the injury under consideration develop this complication. At least it may be said that it is better to have an ulnar nonunion with the radius restored to normal than to leave the patient with a dislocated radial head and no guarantee of ulnar healing. If operation to replace the radial head becomes necessary, as it often does, internal fixation of the ulna may be advisable.

5. Cioran, S., and Sima, C.: Monteggia Fracture with Posterior Dislocation of the Radius, Rare Case, Rev. san. mil., Bucuresti **32**: 622-624 (Dec.) 1933.

Late operations in neglected cases must be adjusted to the conditions present. In case 3 of the present series, which was first seen two and one-half months after injury, it was necessary to resect the radial head and perform a bone graft on the ununited ulna. In this case a procedure was used which has been found to be of value in certain cases of bone grafting and which will be the subject of a future report by Dr. Roger Anderson. After the graft had been fixed in place, Roger Anderson half-pins were inserted into the ulna above and below the graft and the projecting portions were incorporated into the plaster cast in order to effect complete immobilization of the fragments and graft. Use of this technic permitted the use of a short cast, reaching only to the upper third of the arm, with shoulder motion instituted immediately after operation and with excellent healing of the graft.

One final word concerns the radial nerve. In these, as in all fractures, the presence or absence of damage to the nerve should be ascertained before any treatment is undertaken. The deep radial nerve, the motor terminal branch of the radial nerve, passes in front of the lateral part of the elbow joint just where it can be easily injured by a dislocated radial head, and it is better to discover injury to this important nerve before rather than after manipulation or operation. Prompt reduction of the dislocation is usually the only treatment that a bruised radial nerve needs, but operation may be necessary to free it without adding to the injury if the radial head has come into particularly intimate contact with it.

CONCLUSIONS

1. Fracture of the ulna with associated dislocation of the head of the radius, the so-called Monteggia fracture, is a relatively common lesion.

2. The dislocation may be easily overlooked unless one is on the watch for it. In the presence of an ulnar fracture one should instinctively ask "what is wrong with the radius?"

3. If neglected, the injury will usually result in severe disability.

4. Treatment should be prompt. An attempt at closed reduction is permissible only if one realizes that apparent reduction of the radial head, with the forearm flexed, may be illusory and one takes precautions to make sure within a few days that the reduction is real. In these cases, the best specialist available may be cheapest.

REPORT OF CASES

Cases 1 and 2 are reported with the permission of Dr. Harry B. Slocum, chief of staff, Monmouth Memorial Hospital, Long Branch, N. J.

CASE 1.—R. P., a white boy aged 6 years, admitted to the Monmouth Memorial Hospital Aug. 16, 1935, had fallen on the right arm. The forearm and elbow were tender, and any motion of the elbow caused pain. Roentgen examination showed a greenstick fracture of the middle third of the ulna, with slight bowing to the palmar surface and toward the radius, as well as forward and lateral dislocation of the radial head.

Closed reduction of the fracture and dislocation was done under nitrous oxide anesthesia, and a posterior molded plaster splint was applied to hold the forearm flexed to an angle of 45 degrees.

Immediate postreduction roentgenograms showed apparent anatomic replacement of the radial head.

September 3 the splint was removed and the forearm was cautiously extended to 135 degrees without causing displacement of the radial head. Thereafter the splint was removed daily for guarded active motion. At the time of his discharge from the hospital, September 11, he had almost complete extension of the forearm.

Roentgen examination September 10 showed the radial head to be in good position with definite callous formation around the ulnar fracture.

CASE 2.—E. S., a Negro aged 51, admitted to the Monmouth Memorial Hospital Aug. 22, 1935, was struck across the left forearm with a stick during a fight. The left forearm was tender and deformed, with palpable dislocation of the radial head. Roentgen examination showed a comminuted fracture of the ulna, with a triangular loose fragment, and with dislocation of the head of the radius.

The fracture-dislocation was reduced by manual traction and manipulation and a sugar-tongs plaster splint applied with the forearm flexed to less than 90 degrees. Roentgenograms August 24 showed apparent reduction of the dislocation, with the fragments of the ulna in fair alinement, though not in contact.

On September 13 the forearm was cautiously extended, without recurrence of the dislocation. Roentgenograms at this time showed no callus around the ulnar fragments. On October 8, faint callus was visible.

Beginning October 24, the splint was removed for physical therapy but was reapplied after each treatment. Roentgen examinations on November 8 and 27 showed that the radial head was remaining in normal position but showed little increase in callus.

The Wassermann reaction of the blood was positive, and he received antisyphilitic treatment during his stay in the hospital.

He was discharged from the hospital December 10, still wearing a splint, and was almost immediately lost sight of, as he moved to the South. Whatever the ultimate outcome of the ulnar fracture, the radial head was still in normal position almost four months after his injury.

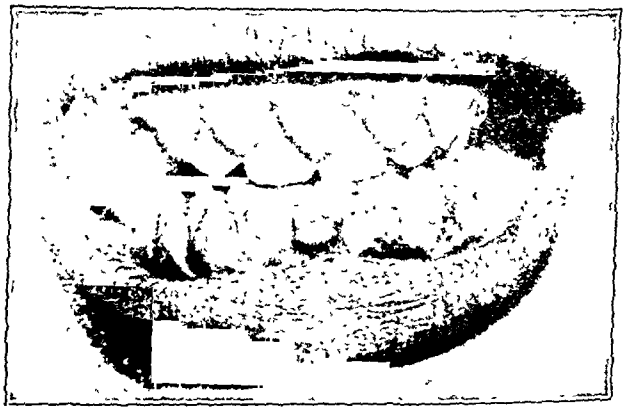
CASE 3.—R. D. A., a white man aged 63, was admitted to the U. S. Marine Hospital, Seattle, on March 16, 1937. Dec. 31, 1936, two and one-half months before admission, he was struck on the left forearm near the elbow by a piece of a stump that he was helping to blast out. The forearm was painful and useless and he was taken to a local physician, who manipulated his arm and applied a plaster cast, which was left on for five weeks and then replaced by another cast, which was left on until the latter part of February. After removal of the cast the elbow was stiff. The same physician manipulated it under anesthesia without benefit.

Examination, March 16, showed the left elbow to be enlarged and irregular. Elbow motion was from 90 to 135 degrees, with practically no rotation. The radial head was palpably dislocated forward and upward, lying in front of the lower end of the humerus. There was moderate atrophy of the muscles of the forearm and hand.

Roentgen examination March 16 showed a comminuted fracture in the proximal third of the ulna with some radial angulation at the site of fracture and no definite repair. The head of the radius was dislocated anteriorly.

The patient was treated with physical therapy for two months and then, as definite nonunion of the ulna was present, was operated on by Dr. Roger Anderson. The radial head was resected and an osteoperiosteal onlay graft from the right tibia was fixed to the ulna after the bone ends had been freshened. Roger Anderson half-pins were inserted into the upper and lower fragments of the ulna through the skin and were incorporated into the plaster cast, which was applied from the hand to the upper third of the arm.

The postoperative course was uneventful except for temporary tourniquet paralysis of the muscles of the left forearm and hand. August 18, the cast, pins and sutures were removed. Both operative wounds were well healed. Roentgenograms at this time showed incomplete bony union. A posterior molded plaster splint was applied which was removed two or three times a day for active motion and which was left off altogether except at night by September 1. He was discharged from the hospital September 7, with elbow motion of from 80 to 135 degrees, with slight rotation. He was seen again October 26, when he was found to have a range of elbow motion of from 60 to 150 degrees. Roentgenograms at this time showed complete bony union of the grafted ulna.



U. S. Marine Hospital.

THE TREATMENT OF EPILEPSY WITH SODIUM DIPHENYL HYDANTOINATE

O. P. KIMBALL, M.D.
CLEVELAND

During the first five months of 1938 a study was made of the treatment with sodium diphenyl hydantoinate (dilantin) of epileptic persons in the public schools of Detroit, where the Special School for Epilepsy had been established as an integral part of the public school system. This drug was considered the most powerful anticonvulsant drug that had been tried, and further use has only strengthened this belief. In view of the toxic effects, I felt that it should not be used except under the careful guidance of a physician.

Regarding the efficacy of sodium diphenyl hydantoinate in the control of seizures, recent observations correspond very closely with those of the aforementioned study and the study of Putnam and Merritt.[1] In twenty-three of the 152 cases under observation the drug has been used for less than three months. Of the remaining 129, the seizures have been entirely controlled in eighty-one, or 62.7 per cent, and definitely

Advanced hyperplasia of the gums.

alleviated in nineteen, or 14.7 per cent, and little or no benefit has been noted in twenty-nine cases, or 22.5 per cent. I wish to emphasize the fact that the general health, the mental state and the personality of the patient are so much better than before the use of sodium diphenyl hydantoinate that the treatment will be continued even though I am reporting some difficulties in this paper.

The development of a sore mouth in some cases in addition to dizziness and a staggering gait was noted, but these two conditions had not been associated. On further observation it was found that some patients had definite hyperplasia of the gums, and occasionally the hyperplasia had developed to such a degree that it suggested scurvy.

Of the 152 patients receiving sodium diphenyl hydantoinate, the majority of whom attend the Special School for Epilepsy, 119 have been reexamined for hyperplasia of the gums, and it is this condition which is emphasized in this report. The gums of fifty-one are normal and of sixty-eight show varying degrees

Dr. E. E. Ecker and Dr. Louis Pillemer made the determination of ascorbic acid in the cases discussed.

1. Merritt, H. Houston, and Putnam, Tracy J.: Sodium Diphenyl Hydantoinate in the Treatment of Convulsive Disorders, J. A. M. A. 111: 1068 (Sept. 17) 1938.

of hyperplasia. Seventeen patients have advanced hyperplasia like that shown in the accompanying illustration. As a matter of record fifty-seven per cent of the patients who have used this drug two months or more show changes in the gums to some degree. Some patients who have taken it continuously for eleven months show no change; others, who have taken it for as short a period as two months and in smaller doses, show definite hyperplasia associated with vitamin C deficiency. Some had a sore mouth and tender gums for a short period starting about two weeks after the beginning of therapy. The soreness cleared up and no further thought was given to this condition until the progressive hyperplasia was noted. In only four cases is the advanced hyperplasia associated with soreness and petechial hemorrhages on pressure, and in each of these there is an associated gingivitis. No patient who has employed good oral hygiene has any suggestion of sponginess or bleeding. The others show a smooth firm hyperplasia that does not bleed easily and is not particularly tender. Forty of the sixty-eight patients who show this peculiar hyperplasia of the gums have or have had dizziness associated with an unsteady swaying gait and spells of unusual weakness.

Ascorbic Acid Content of the Blood Serum

Group	Mg. per 100 Cc.
Normal	1.14
One plus	0.58
Two plus	0.55
Three plus	0.47

Beginning August 15, ascorbic acid was prescribed for one patient. With 300 mg. daily the condition of the gums was only slightly improved in three weeks. The use of a diet high in vitamin C was continued, yet on October 25 an analysis of the blood serum showed the ascorbic acid level to be 0.1 mg. per hundred cubic centimeters, which is about one tenth of normal. Because of this unusual observation, similar studies were made on thirty-four children in the Special School for Epilepsy. Those showing definite beginning hyperplasia were designated one plus, those with rather advanced hyperplasia two plus and those with extreme hyperplasia, as seen in the illustration, three plus. A group showing no changes in the gums was included. The physical condition of the patient was not known to the serologist at the time the blood studies were made. The amount of ascorbic acid found in the blood serum of these groups is indicated in the accompanying table, the amount given being the average for each group of eight patients.

No patient with normal gums showed a deficiency in ascorbic acid and, conversely, every patient with marked hyperplasia of the gums showed a definite deficiency of vitamin C. Therefore it is concluded that the deficiency of ascorbic acid parallels the degree of hyperplasia of the gums.

REPORT OF A TYPICAL CASE

A youth aged 18 had suffered from grand mal attacks since the age of 15. May 7, 1938, treatment with 0.4 mg. of sodium diphenyl hydantoinate daily was started, and, although he had averaged eight grand mal seizures a week for the previous two years, he did not have a seizure in six months during which he received this drug. Two weeks after the beginning of treatment he complained of soreness of the gums; this disappeared in about two weeks. By the first of July enlargement of the gums was evident to the patient and to his family. By August 1 it had progressed to such an extent that his dentist advised surgical removal of some of the tissue. Beginning August 15, 300 mg. of ascorbic acid was given daily for three weeks, with very little effect. September 7, use of the excessive amount of ascorbic acid was discontinued but a diet high in vitamin C was substituted. October 25 the ascorbic acid content of the blood serum was 0.1 mg. per hundred cubic centimeters. Also on this date the photograph accompanying this report was taken. Because of the parents' concern over the low vitamin C content, without my knowledge they resumed the treatment with ascorbic acid, 300 mg. daily. November 22 the ascorbic acid content of the blood serum was found to be 1.8 mg. per hundred cubic centimeters, a high normal value. At this date his gums showed some improvement. Because of the striking result in the control of seizures, improvement in the mental state and disposition, treatment with sodium diphenyl hydantoinate, 0.3 Gm. daily, was continued.

The usual symptoms of severe and prolonged vitamin C deficiency (scurvy), such as purpura, sore joints and extreme weakness, have not been seen. In general the patients are in a very satisfactory condition except for the gingival hyperplasia associated with vitamin C deficiency. As to this condition, it is known so far only that (1) there is a definite relationship between the changes in the gums and the low ascorbic acid level (the severity of the hyperplasia appears to parallel the decrease in vitamin C) and that (2) this condition seems to be associated with the treatment with sodium diphenyl hydantoinate.

Further studies are in progress, the results of which will be given in a later report.

Clinical Notes, Suggestions and New Instruments

HERNIA INTO THE PARADUODENAL FOSSA WITH OBSTRUCTION DUE TO LARGE BILIARY CALCULUS

I. A. ARNOLD, M.D., LOUISVILLE, KY.

Since I reported this case in December 1933, my attention has been called to the reports on paraduodenal hernia by Baumeister and Hanchett.[1] They report only on right paraduodenal hernia and have found but forty-four cases of this particular type of internal hernia. One was the case which I am now reporting. I have been able to find no other case in the literature in which the obstruction in the hernia was due to a large gallstone.

REPORT OF CASE

History.—Mrs. L. F., aged 70, white, was admitted to Norton Infirmary Jan. 29, 1933. Her present illness began seven days before admission to the hospital, immediately following a meal which had made her very sick. The symptoms began with vomiting accompanied by severe pain in the epigastric region which, however, subsided for a period of twenty-four hours, when she began to have intermittent cramps, pain and nausea. This condition lasted for a few hours and then subsided, only to recur on eating, after which she would invariably vomit her food in from one to three or four hours. She became progressively worse and at the time of her admission the vomiting was feculent. From the history obtained, she never at any time suffered the severe pain that one would be supposed to experience from an intestinal obstruction; neither was the distention of the abdomen marked. I was unable to obtain a past history that would tend to have any bearing on the present condition.

From the Surgical Clinic of the Norton Infirmary.

1. Baumeister, Carl, and Hanchett, McMicken: Right Paraduodenal Hernia, Arch. Surg. 37: 327 (Aug.) 1938.

Examination.—Physical examination revealed arcus senilis, generalized arteriosclerosis, slight cardiac hypertrophy, and a definite systolic murmur at the apex and aortic and pulmonic areas. The second sounds were weak. The blood pressure was 110 systolic, 66 diastolic. Pulmonary congestion was marked. The abdomen was slightly distended and markedly rigid. Peristaltic waves were detected but were not vigorous.

Urinalysis revealed a cloudy appearance, an acid reaction and a specific gravity of 1.020; tests for bile and urobilin were negative.

Microscopic examination revealed numerous squamous epithelial cells, mucous threads, many pus cells and an occasional red blood cell.

A blood count showed 4,530,000 red blood cells, 21,000 white blood cells, hemoglobin content 80 per cent (12 Gm.), color index 9, neutrophils 24 per cent, basophils 1 per cent, monocytes 6 per cent and lymphocytes 3 per cent.

A diagnosis of intestinal obstruction and probably carcinoma was made, and the patient was operated on immediately under spinal anesthesia preceded by one sixth grain (0.01 Gm.) of morphine and 1/200 grain (0.0003 Gm.) of scopolamine hydrobromide.

When the abdomen was opened through a right rectus incision in the upper part of the abdomen there was a pronounced discoloration and slight distention of the small intestine extending from the pylorus downward about 5 feet, where a loop of the intestine went through the opening formed by the ligament of Treitz and was twisted on itself. There was a large mass in the hernia which proved to be a gallstone. After the obstruction had been relieved and the stone had been removed from the small intestine the color gradually returned to the bowel above the obstruction. On examination of the gallbladder region there was found at the junction of the common duct to the duodenum a fibrous band, but no definite gallbladder could be made out. Owing to the desperate condition of the patient no further examination was deemed advisable. The abdomen was closed in the usual manner with four stay sutures.

At the time of the operation 1,000 cc. of 10 per cent dextrose and saline solution was given intravenously; a stomach lavage was also done. At first there was pure feculent matter; the lavage was continued until the fluid returned clear. She was very quiet through the operation; this we later attributed to coma, since she never rallied or regained consciousness.

AUTOPSY

The autopsy was performed by Dr. A. J. Miller. The body was well developed and well nourished. The abdomen was rotund but not distended. In the region of the upper right rectus there was a recent surgical incision.

The stomach was filled with gas and a small amount of fecal liquid and contained four faceted gallstones about 5 mm. in their longest diameter. In the right lateral wall of the second portion of the duodenum was an ulceration entirely through the wall of the duodenum and communicating with the lumen of the gallbladder. The gallbladder was shrunken and fibrous, surrounded by fat tissue. The cavity seemed to be limited to this fistula, which was about 2.5 cm. in diameter. An opening into the cystic duct was not demonstrated. Apparently the fistula between the duodenum and the gallbladder was formed by the erosion of a stone from the gallbladder into the digestive tract. The hepatic tract was patent, as demonstrated by gently milking it and expressing bile into the duodenum. The remainder of the tract was not opened. The duodenum and jejunum were dilated and hemorrhagic for a distance of about 4½ feet. Beyond this point the small bowel was collapsed and the large bowel also was not distended. At this point in the jejunum, about 4½ feet from the duodenum, there was a recent surgical incision opposite the mesenteric attachment. It is reported that a large gallstone was removed from this location and that this loop of the intestine was found at operation to be herniated under the ligament of Trietz. The ligament of Trietz was examined and found to be hemorrhagic, swollen and softened.

The liver was soft, light colored and blotched.

The pancreas contained a few small flecks, evidently the result of old fat necrosis.

The right kidney was light colored and soft but not dimpled.

The pelvic viscera were not remarkable, except for small calcified fibroids attached to the uterus.

In this case the fundus of the gallbladder had anastomosed itself to the duodenum just opposite the ampulla of Vater. An opening was formed by the pressure of a large stone and from the different colors of the ends of the stone it had been partially delivered into the duodenum for some time, as it showed evidence of having been acted on by the gastric juices. During the first siege of vomiting the delivery was completed. The stone passed down into the jejunum for about 5 feet and lodged where a portion of the intestine had gone into the left inferior paraduodenal jejunal fossa. This knuckle with the stone inside was twisted on itself and had gone downward, backward and outward for about 5 inches behind the peritoneum. A large mass could readily be felt posterior to the peritoneum. When the intestine was delivered from the hernial fossa this hard mass proved to be a large biliary stone. The intestine was incised and the stone removed.

It is difficult to describe as well as to demonstrate this hernia so that others may see how it can happen. When the colon and stomach are lifted to show the fossa, the greater portion of it disappears, but with the finger in the fossa and the intestine turned down in its normal position the fossa greatly increases. It is only then that one can visualize how this hernia occurs.

Sherrill, in his book on peritonitis, gives a graphic description of the anatomic conditions of the left duodenojejunal fossa, where these hernias not infrequently occur.

Moynihan[2] describes nine of these rudimentary fossae about the duodenojejunal flexure in which the internal hernia may be found. The most important are the superior and inferior paraduodenal folds and the fossae of Waldeyer and Landzert.

Steinke[3] in my opinion has made the best classification of paraduodenal hernias. He classifies them as right, left and duodenojejunal, superior and inferior. The one under discussion would come under the duodenojejunal inferior.

Hallock[4] presented a specimen of duodenojejunal hernia before the Chicago Surgical Society in 1917, and in his case it was found post mortem that the hernia went upward and backward, but in my case the hernia went downward and backward.

Dowdle[5] reports thirty-four cases of the right and 105 of the left that have been recorded in the literature. Of the thirty-four cases of right paraduodenal hernias, seventeen came to operation and seventeen were found at autopsy. Of the seventeen patients operated on there were six recoveries and eleven deaths. His case made the thirty-fifth reported, the eighteenth to come to operation and the seventh in which recovery occurred.

The latest data that I have been able to find on internal hernia are those of Steinke, quoting Short.[6] To date there have been 203 paraduodenal hernias, including forty-eight in the left duodenojejunal fossa, but in the record of these cases there is not a single case which shows the obstruction in the herniated intestine to be that of a gallstone, as in my case.

SUMMARY

The illness here reported evidently began as cholelithiasis. One of the large stones eroded its way through the gallbladder and duodenum, forming a cholecystoduodenal fistula. This stone became impacted in the jejunum 4½ feet from the duodenum, and this impacted loop became herniated beneath the inferior duodenal fold, resulting in complete obstruction of the small intestine.

The patient's death is attributed to complete obstruction of the jejunum. The small stones were evidently regurgitated from the duodenum into the stomach, having passed through the fistula.

PNEUMOCOCCUS TYPE XIV PNEUMONIA IN TWINS; CONTRASTED TREATMENT

JESSE G. M. BULLOWA, M.D., NEW YORK
Visiting Physician, Harlem Hospital and Willard Parker Hospital.

Opportunity to contrast the effect of two methods of therapy in human litter mates (identical twins) is sufficiently unusual to warrant this brief report:

Evelyn H., aged 17 months, had cough and coryza May 6, 1938, and on the following day an elevation of temperature. May 9 the swelling of the eyes and a facial rash appeared and the following day vomiting and fever. May 11 the rash was fading but a sore throat and some dyspnea developed. She was admitted to Willard Parker Hospital May 12, appearing acutely ill, with an elevation of temperature to 104.2 F., an increased respiratory rate and a faint maculopapular rash on the face and thighs, with macular staining behind the ears. The ear drums were normal, the conjunctivas slightly reddened and the eyelids swollen. The tonsils were large and moderately congested; there were no Koplik spots. The breath sounds were suppressed at the bases of both lungs; there were dulness, diminished voice sound and a few coarse rales at the base of the left lung. There was slight impairment at the base of the right lung posteriorly, with areas of bronchovesicular voice and numerous rales and rhonchi over both pulmonary fields. Hepatic dulness was slightly increased. The child cried constantly during the examination. Two hours after admission pneumococcus type XIV was recovered on a pharyngeal swab. After a negative cutaneous test, 57,000 units of pneumococcus type XIV rabbit serum with 5 minims (0.3 cc.) of epinephrine in 150 cc. of physiologic solution of sodium chloride was introduced into the external jugular vein. Three days later the child was well, although signs at the base of the left lung persisted for ten days after treatment. The blood culture was positive on admission. She was discharged May 31, nineteen days after admission, and has been well since.

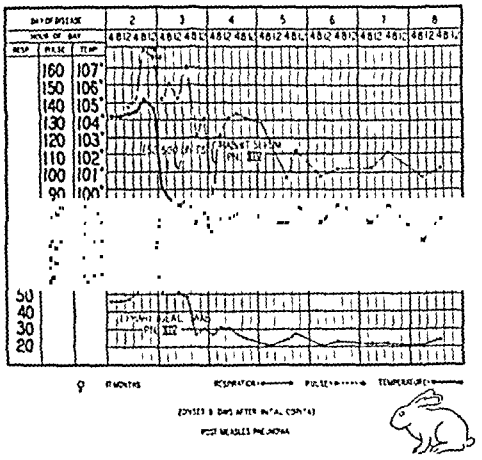

Chart 1.—Course of the twin who received serum therapy promptly.

Emily H., aged 17 months, who had coryza and a slight cough May 7, 1938, was admitted to Willard Parker Hospital May 12 with fever, a faint maculopapular rash, coryza, cough and conjunctivitis. There were no Koplik spots. The temperature was 101 F., the pulse rate 100 and the respiratory rate 24. The lungs were clear. The fever disappeared the next day; the pulse rate was 118 and the respiratory rate 30 on one occasion. The temperature ranged from 98 to 99 F.; pulse rate was below 100 and the respiratory rate 20 until May 20, at which time she was discharged in good condition. May 23 she was admitted to Harlem Hospital, where her mother stated that the patient had not been well since discharge from Willard Parker Hospital, a severe cough having developed that evening and continued to the next day. May 22 she was feverish and sweated and was restless. On admission there were rales scattered throughout the lungs. On the day after admission to Harlem Hospital, x-ray examination revealed an infiltration extending outward from both hilar regions. Pharyngeal culture yielded pneumococcus type XIV. Emily chanced to fall into the serum control group of type XIV, and accordingly no serum was at first given. Her course in the hospital was a stormy one; there were daily elevations of temperature to between 104 and 105 F. for eight days, with profound prostration and rapid pulse. During this time she deteriorated steadily, losing considerable flesh and strength despite removal to the atmosphere control room (oxygen) and excellent nursing care. On the tenth day of illness the blood culture yielded pneumococcus type XIV. Culture the next day was also positive. Because of the persisting bacteremia, it was decided to administer serum. Accordingly, 164,000 units of homologous rabbit serum was given intramuscularly and 68,250 units intravenously. There was an abrupt drop in temperature (chart 2) and only a slight rise during the subsequent two days, the temperature finally becoming normal on the third day after treatment. Blood culture on the day serum therapy was begun proved to be sterile. Whether this was evidence of permanent or only transitory improvement cannot be determined. According to my experience a single negative blood culture in non-serum treated disease due to pneumococcus type XIV is no guaranty against the recurrence of overwhelming invasion.

The course of the second child was in striking contrast to that of the twin sister treated immediately with homologous antipneumococcus serum, who was well within three days of treatment and escaped the hazards incident to prolongation of fever and to bacteremia.

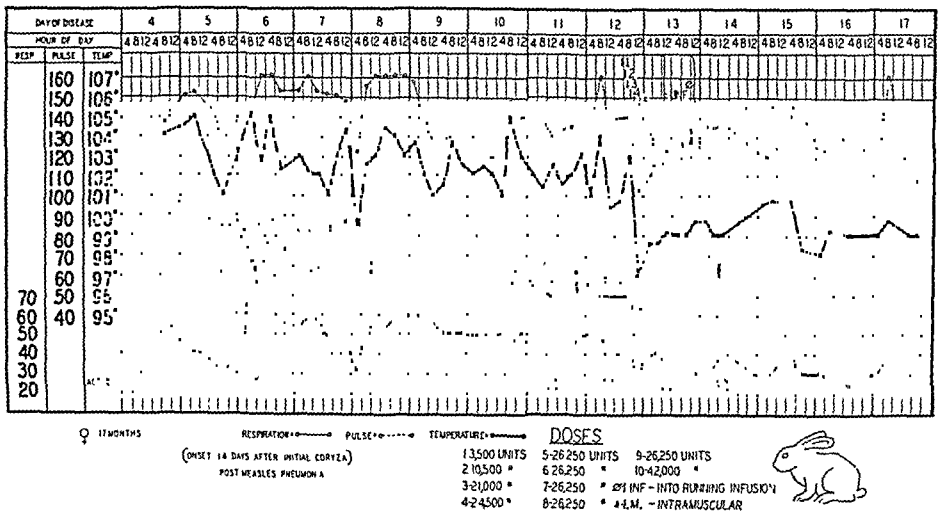

Chart 2.—Course of the twin from whom serum therapy was at first withheld.

SUMMARY

One of a pair of identical female twins with pneumococcus type XIV pneumonia complicating measles was treated immediately with homologous antipneumococcus serum, responded promptly and had a short course. The other twin, from whom serum was at first withheld, had a much longer, stormy course, with bacteremia, and then responded favorably to the administration of serum.

62 West Eighty-Seventh Street.

This study received financial support in part from the Littauer Pneumonia Research Fund of New York University College of Medicine, from the Metropolitan Life Insurance Company and from Mr. Bernard M. Baruch, Mr. Bernard M. Baruch Jr., Miss Belle N. Baruch and Mrs. H. Robert Samstag. The patient in Harlem Hospital was studied and treated with the permisson of Dr. Morris Gleich, director of pediatrics.

SPONTANEOUS FEVER THERAPY IN NEUROSYPHILIS

F. E. WEATHERBY, M.D., EL PASO, TEXAS
Lieutenant Colonel, Medical Corps, United States Army

Spontaneous generalized tetany and a rectal temperature of 106.4 F. in a case of neurosyphilis, followed by marked clinical improvement, are believed to be sufficiently unusual to merit recording.

REPORT OF CASE

A woman of 31, without known syphilitic history, whose mother was said to have committed suicide while insane, had been previously married from 1923 to 1929 and had one pregnancy, giving birth to a daughter, who was 13 at the time of examination and in apparent good health. The patient had been married to her second husband since 1929, with no pregnancies.

On the day of admission she got up at 5:30 a. m., cooked breakfast and did housework in her usual manner but was observed to be out of contact with her surroundings at 7:30 a. m. She did not know the time or place, did not recognize any one and talked incoherently. At 8 o'clock she became unconscious and within a few minutes had a severe convulsion with flexion and adduction of the upper extremities, extension of the lower extremities and opisthotonos. During that day she was never free from mild or severe spasm, did not regain consciousness and had involuntary micturition and defecation.

On arrival at the hospital at 8:30 p. m., she was unconscious, with the body rigid, the jaws tightly closed, the arms forcibly flexed at the elbows, the wrists and metacarpophalangeal joints flexed and the fingers extended, the thumbs flexed into the palms, the legs rigidly extended, the feet pressed downward at the ankles and the toes extended in dorsiflexion. With increase of the spasm she occasionally presented opisthotonos. Chvostek's and Trousseau's signs were readily elicited. Her head was retracted, the eyes closed and the eyeballs rolled so that the pupils could not be readily examined when the eyes were opened. The tendon reflexes were exaggerated, and patellar clonus was present bilaterally. Increased extension of the toes was caused by plantar stimulation, and Babinski's sign was marked on the right. Abdominal reflexes were not obtained. Breathing was rapid, with an expiratory groan of automatic character. The systolic blood pressure was 110 and the diastolic 60. Her weight was 108 pounds (49 Kg.).

Urine obtained by catheter was alkaline and contained albumin and granular casts. The blood count showed 13,000 white cells, with 79 per cent granulocytes. The spinal fluid was clear, dropped slowly and showed increased globulin and 39 white blood cells, of which 34 were lymphocytes. A report received later showed the Wassermann reaction to be 4 plus in all dilutions, including 0.2 cc.; the colloidal gold reaction was 5553100000. There were 4 plus Wassermann and Kahn reactions of the blood, the quantitative Kahn test being reported as showing 40 units. The carbon dioxide combining power of the blood was 84.4 cc., the nonprotein nitrogen content 30 mg. and the sugar content 66.6 mg. per hundred cubic centimeters.

The patient was given 10 cc. of 10 per cent calcium gluconate intravenously. (Two more injections of the same amount were given the next day.) The gastric contents were opaque and greenish blue. No poisons were discovered. The stomach was washed and 300 cc. of water allowed to remain.

The temperature on admission was 103.8 F. (axillary), the following day 102 F. (axillary) at 8 a. m., 104.4 F. (rectal) at noon and 105.4 F. at 4 p. m. The spasmodic state continued, although the manifestations were less severe, and the patient remained unconscious and incontinent. Ophthalmoscopic examination showed normal fundi. The carbon dioxide combining power dropped to 49 cc. and the nonprotein nitrogen content rose to 39.9 mg. and the sugar content to 166 mg. per hundred cubic centimeters. The calcium content of the blood was 6.2 and later 6.4 mg. By 11 p. m. the temperature had risen to 106.4 F. (rectal) and ranged from 104.6 F. at 6 a. m. to 105.4 F. at 4 p. m. on the third day. A fatal outcome was expected.

Tryparsamide 1 Gm. was given intravenously at 6 p. m. The temperature was 105.2 F. at 7 o'clock but fell to 101.4 F. by midnight. The patient was delirious, restless and screaming during the night but was quiet the next day, and her temperature did not rise above 99 F. Tryparsamide 1 Gm. was repeated. Vomiting was frequent but ceased after a saline purge. The patient was conscious and able to talk, and her muscles were relaxed. Although she was occasionally restless, disturbed and noisy during the next two nights, her condition rapidly improved, she took nourishment well and she had no recurrence of fever.

A third injection of 1 Gm. of tryparsamide was given two days after the second, followed by 2 Gm. five days later and another 2 Gm. after a three day interval. In three more days an injection of 3 Gm. of tryparsamide was given. This was repeated one week later, after which weekly injections of a bismuth preparation were begun.

The patient walked outdoors ten days after she came to the hospital and had no recurrence of spasm or mental symptoms, although she had no memory of the period of her acute attack. Neurologic examination gave entirely negative results except for a somewhat limited pupillary reaction to light. Seven weeks after the onset of acute symptoms the Wassermann and the Kahn reaction of the blood remained 4 plus, but the quantitative Kahn test showed a drop to 15 units. The spinal fluids showed 8 cells, a heavy trace of globulin, a Wassermann reaction still 4 plus in 1 cc., 0.7 cc. and 0.5 cc. but 3 plus in 0.2 cc., and a colloidal gold reaction of 4543100000.

COMMENT

High temperatures have been reported in cases of cerebral syphilis, but they have usually been associated with acute meningeal reactions and the presence of many cells in the spinal fluid. In the most acute stage this patient showed only 39 cells. Involvement of the hypothalamic centers is a possible explanation of the hyperpyrexia.

Rapid clinical improvement without residual mental symptoms is probably to be attributed to the spontaneous fever as well as to subsequent antisyphilitic medication.

From the Neuropsychiatric Section, Medical Service, William Beaumont General Hospital.

DYSPNEA DUE TO TWIN ABSCESSES AT THE SIDES OF THE LARYNX

VIRGIL J. SCHWARTZ, M.D., MINNEAPOLIS

Abductor paralysis of both vocal cords is, fortunately, a very unusual occurrence. Like unilateral abductor palsy, it is practically always due to organic disease. Thomson states that it is due either to bilateral pressure on the recurrent nerves or to a bulbar lesion, usually syphilitic, involving the recurrent centers in the medulla, which are situated in the floor of the fourth ventricle. If the cardiac inhibitory center is also involved, as evidenced by a rapid pulse without fever, and if other nearby cerebral centers are affected, such as those of the eyes, tongue and pharynx, the localization points rather definitely toward the medulla. If, however, these signs are not present, one concludes that there is simultaneous peripheral involvement of the two recurrent laryngeal nerves. This rare condition is illustrated by the following case:

G. E., a woman aged 30, was brought into the hospital complaining of extreme difficulty in breathing of only four hours' duration. Pain and swelling had appeared in the ankles and knees about eight days before; these became rapidly worse and spread to the wrists, elbows and shoulders, although the ankles were the most severely involved. These symptoms were accompanied by chills and fever. A few hours before admission the patient had noticed sudden inspiratory difficulty, and she was sent to the hospital. The past history contained nothing relevant.

At admission the temperature was 104.6 F. by rectum, the pulse rate 138, the respiratory rate 28 and the blood pressure normal. There were cyanosis and severe inspiratory difficulty with stridor. The joints of the toes, fingers, ankles, knees, elbows, wrists and shoulders were swollen, hot, tender, and discolored with bluish red patches. There were a number of pustular eruptions on the buttocks. The urine showed a 4 plus

reaction for albumin, a few granular casts and a few pus cells. The hemoglobin content was 88 per cent, the red cell count 4,300,000 and the leukocyte count 7,500.

Laryngoscopic examination showed abductor paralysis of both vocal cords. In fact, it soon appeared that almost every laryngeal nerve and muscle must be paralyzed. A tracheotomy was done, and the patient's respiration at once became free, corroborating what we had previously seen during bronchoscopic examination, namely that there was no pathologic change in the trachea or bronchi and that the dyspnea was due entirely to the paralysis of the vocal cords. The patient's other conditions, however, did not improve, and she died the following day.

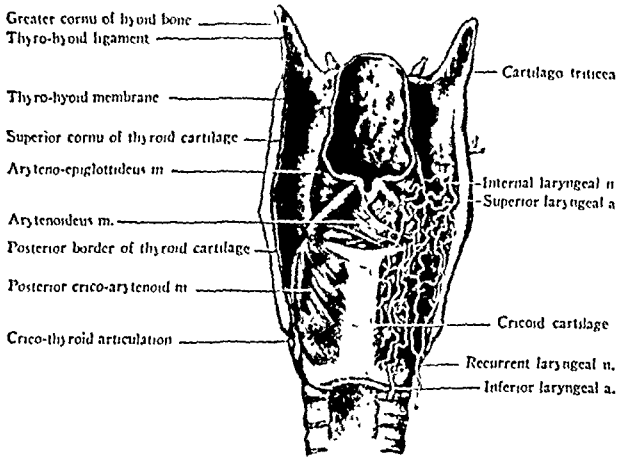

Fig. 1.—Posterior aspect of the larynx, showing nerves, vessels and muscles. Note particularly the course and distribution of the nerves and compare with figure 2. (From J. B. Deaver's "Surgical Anatomy"; reproduced by permission of P. Blakiston's Son & Co.)

At autopsy it was found that the left ankle joint was filled with creamy pus. The other joints contained a colorless serous fluid. The pathologist believed that bacteremia must have been present, although a blood culture was not made. During removal of the left lobe of the thyroid gland a small amount of thick pus escaped from the connective tissue posterior and lateral to the thyroid cartilage. On further inspection at the point where the pus had oozed out there was found an abscess about 2 cm. long and from 0.5 to 1 cm. wide posterior and lateral to the larynx. The pathologist then decided to inspect the opposite side, and he found there exactly the same sort of an abscess, localized in the same manner and apparently not connected in any way with the one on the left. In other words, these abscesses were probably metastatic, each one having developed independently by deposition of blood-borne bacteria, which doubtless came originally from the left ankle joint. The formation of one such abscess would be strange enough, but the development of two, one on each side, of exactly the same size and shape and in identical locations, causing pressure on the nerves entering and leaving the larynx so as to produce precisely the same type of pathologic change in the two sides, is a circumstance that could not have been more accurately executed if it had been deliberately planned.

Fig. 2.—Larynx of G. E., posterior aspect (same view as figure 1). The indicators (*x*, *x*) point to abscess cavities (dark areas) at each side of the larynx. These were the cause of the paralysis.

PELLAGRA WITH PSYCHOSIS AND MINIMAL PHYSICAL SYMPTOMS

VERNON L. EVANS, M.D., AURORA, ILL.

The prompt response of pellagra to nicotinic acid therapy, as recently reported by a number of writers,[1] affords an excellent therapeutic test and may show the presence of pellagra in many cases of hitherto undiagnosed disease. The following case is believed to bear this out:

REPORT OF CASE

A single woman aged 38 had been unable to work for eleven years owing to weakness, headaches, undernourishment and anorexia. There had been no ingestion of drugs. The patient had believed herself subject to disease of the stomach and gallbladder, and there were numerous physical complaints.

Aug. 1, 1938, she entered a general hospital for study and treatment. There were no "mental" symptoms at that time. While she was there, complete anorexia developed, and the patient became suspicious, hostile, disoriented and violent. When members of her immediate family came to see her she did not recognize them.

August 12 the patient was transferred to Mercyville Sanitarium. On admission she was disoriented, resistive and combative. She seemed to be having vivid visual hallucinations.

The patient was emaciated. She resisted every step of the examination. She had to be held on the scale, so that the determination of weight was only approximate, at about 73 pounds (33 Kg.); the height was 5 feet 1½ inches (156 cm.). The pulse was rapid but could not be counted accurately because of the continuous twisting and pulling of the patient. The temperature was normal and the blood pressure 130 systolic and 95 diastolic. The mucous membrane of the mouth and tongue was rather more red than normal but not markedly so. The extremities were thin and there were a few scattered bruises. There was no dermatitis. The patient flopped about in a haphazard manner and had to be forced to do nearly everything, but there was apparently no incoordination, as she struck at those about her with fair accuracy. The reflexes could not be tested, owing to the resistiveness and rigidity of the patient. The physical examination gave negative results otherwise.

The hemoglobin content was 12.8 Gm. (Sahli), the erythrocyte count 4,420,000 and the white blood cell count 7,400. Urinalysis gave negative results.

The patient refused all food and drink and required forced feeding.

August 15 she received 500 mg. of nicotinic acid in divided doses, placed in her feedings. This dose was given daily thereafter. The next day she took food voluntarily. The following day she conversed rationally but still was rather hostile and believed that she was being mistreated. She wrote a fairly intelligent letter home. At the end of four days she was perfectly rational in her conversation, became agreeable and cooperative and stated she was feeling much better.

1. Pellagra and Nicotinic Acid, editorial, J. A. M. A. **110**: 289 (Jan. 22) 1938. Spies, T. D.; Cooper, Clark, and Blankenhorn, M. A.: The Use of Nicotinic Acid in the Treatment of [illegible] (Feb. 26) 1938. Advances in the Treatment [illegible] Ann. Int. Med. **11**: 1760 (March) 1938.

Since then the patient has had the freedom of the building and grounds, and she has been friendly and cooperative. She has been eating well, and on Sept. 1, 1938, her weight was 85½ pounds (39 Kg.).

SUMMARY AND CONCLUSIONS

The case reported would probably have been classified as one of schizophrenia or toxic psychosis if it had not been for the therapeutic test afforded by the nicotinic acid. Drug intoxication was definitely ruled out. Careful inquiry failed to reveal any history of the taking of barbiturates or other sedatives prior to the onset of the psychosis. The only physical symptom of pellagra noted was the moderate glossitis and stomatitis. There was no diarrhea, and the patient after recovery reported only a tendency to constipation.

The clinical picture was of a patient who had suffered for several years from a psychoneurosis with anorexia nervosa and malnutrition. This had culminated in a severe psychosis, which promptly and dramatically responded to the administration of nicotinic acid, the antipellagra vitamin.

CONFERENCES ON THERAPY

TREATMENT OF CONVULSIONS

NOTE.—*These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students, and visitors.*

DR. HARRY GOLD: The subject of the conference today is the treatment of one of the most dramatic symptoms encountered in the practice of medicine, namely convulsions.

Two features characterize this symptom, and both have an important bearing on the problems of treatment. First of all, convulsions almost invariably present an emergency. Secondly, as a symptom the convulsion not only is a manifestation of disease but is in itself a menace to life; how serious a menace to life probably depends in part on the condition in the course of which the convulsions occur. In the pharmacology laboratory this fact can be readily demonstrated. For example, a fatal dose of camphor may cause convulsions during a period of many hours before death occurs. After a fatal dose of nicotine, however, death may occur following only two or three convulsions. That death is due in the latter case to the convulsions is clear from the fact that, if the convulsions are prevented or promptly arrested, the animal survives. It behooves us to give some thought to the question of how dangerous a convulsion in a given situation may be. Its treatment often involves heroic doses of drugs, and the danger of the treatment must be balanced against that of the convulsion itself. We need to consider therefore not only the general treatment of convulsive seizures but the special problems presented by the various and diverse clinical conditions in which convulsions occur. How some of these are managed and how the more important drugs are put to use most effectively in the treatment of convulsive states will be considered this morning.

I have here a list of the more common agents used in the management of convulsions, some of which will be discussed: ether, chloroform, chloral hydrate, paraldehyde, bromides, barbiturates, morphine, magnesium sulfate, calcium salts, hypertonic dextrose, vitamin D, parathyroid extract, dilantin and the ketogenic diet. Dr. Wolff will lead the discussion.

DR. H. G. WOLFF: The following remarks are based on the thesis that the convulsion is a symptom and should be treated as such. There are sixty or more known causes for the convulsion in man. We may therefore waive a discussion of the varieties and turn to the management of the convulsion itself. Most convulsions occur singly and the patient requires no further attention other than that which would be given to any one who has fallen to the ground and is having violent adventitious movements. This means protection from neighboring objects and protection of the tongue. It does not mean bruising the gums or knocking out teeth with instruments in an attempt to open the mouth. The patient should, when possible, be secluded from the crowd or family, often greatly disturbed by this dramatic incident. A dose of 60 mg. of soluble phenobarbital may be given intramuscularly. Commonly the patient will soon recover and be able to return to his home or go on with his work. If he does not he may be taken to a hospital to regain consciousness.

One warning: When planning in response to an urgent call for help to give an unconscious patient caffeine, see that it is not the unconsciousness that follows a convulsion, for under those circumstances it is obvious that the effect may be opposite from that desired.

Should convulsions occur in series, as they sometimes do in epilepsy, or in eclampsia or following drug intoxications, other steps must be taken. It is then desirable to put the patient in a dark quiet room and give intravenously from 180 to 300 mg. of soluble phenobarbital very slowly, so that the injection takes five minutes in all. If at the end of a half hour the patient is still quivering or having myoclonic jerks or has another seizure, an additional 60 mg. of soluble phenobarbital may be given slowly by the intravenous route. If necessary, the administration of 60 mg. doses may be repeated at half hour intervals until a total of 1.2 Gm. in twenty-four hours has been given. This may be considered the upper limit of safety.

As an alternate for the management of a series of convulsions, the following is suggested: a subcutaneous injection of 15 mg. of morphine sulfate and 0.5 mg. of scopolamine hydrobromide. As a second alternate ether anesthesia may be administered for one to two hours. However, the use of the barbiturates is in general preferred.

With regard to eclamptic convulsions some additional comments may be made. The management introduced by Stroganoff I will briefly outline. The patient in impending eclampsia, who has either had a convulsion or would seem to be about to have one, is placed in a dark quiet room and immediately given 15 mg. of morphine sulfate. One hour later the patient is given 2 Gm. of chloral hydrate by rectum if unconscious, in 100 cc. of physiologic solution of sodium chloride or, if alert, by mouth in an equivalent amount of milk. Three hours later 15 mg. of morphine sulfate is given once again; seven hours later 2 Gm. of chloral hydrate by mouth or rectum, thirteen hours later 1.5 Gm. of chloral hydrate, and finally, twenty-one hours later, 1.5 Gm. of chloral hydrate. This is an arbitrary program, and sodium bromide in equivalent amounts may be substituted for the chloral hydrate. It insures more

or less continuous sedation for about twenty-four hours, which is usually all that is needed.

Uremia usually offers the special problems of the treatment of nephritic patients, but the convulsions can be controlled when necessary by the procedures already outlined for the management of status epilepticus.

The prevention of convulsions is the second topic for consideration. I have mentioned before that there are many causes of convulsions, and after a careful search one is unfortunately often left with the diagnosis of idiopathic epilepsy or convulsions of undetermined origin. In such instances, or in case a cause is found that cannot be removed, one is obliged to proceed in a manner that will prevent or reduce the number of convulsions. How may this be done? The facts outlined in the accompanying table are true of convulsions in general.

What are the factors that increase the likelihood, and what are the factors that decrease the likelihood of convulsions? In this table those that prevent are on the left, and those that precipitate or increase the likelihood are on the right. Acidosis, produced by fasting, fat diet, ingestion of acids, such as mandelic acid, or acid-forming salts, such as ammonium chloride, breathing high carbon dioxide, low chloride, high calcium, normal sugar, low fluids reduce the likelihood; while high chloride, low calcium, hypoglycemia, and hydration increase the likelihood. Further, adequate sleep prevents, while inadequate sleep with fatigue acts as a precipitating factor; constructive emotions making for contentment prevent, while destructive emotions, tension, rage, resentment, frustration and boredom have the opposite effect. The factors of lesser clinical importance I will not discuss.

In the management of the patient the first five in the list are most important. If I were to guess about the relative value of the various factors in management I would say that the constructive emotions and sleep will rate about 40 per cent, attention to chemical factors including sedatives and water intake, perhaps 30 to 40 per cent, and all the other factors put together, about 10 per cent.

In the first place, patients who have only one or two convulsions a year are better off without sedation. Before drugs can be used with any satisfaction, three sets of facts should be known: The first concerns the problem of age: At what ages are convulsions most likely to occur? Most convulsions occur in the first twelve months of life. There is another peak in incidence at adolescence, and a third peak at age 60 or thereabouts. There are minor peaks at 7 and at 25. Second, when in the twenty-four hours in any given individual are convulsions most likely to occur? Fifty per cent of convulsions occur between 10 p. m. and 5 a. m., another 15 per cent between 5 a. m. and 9 a. m., and 35 per cent throughout the rest of the day. Also in this climate more convulsions occur in the darker or colder months than in the summer months. Lastly, in women convulsions are more apt to occur in association with menstruation, either before, during or after, than at other times.

We may now continue with the discussion of the management and prevention of attacks by the use of drugs. Phenobarbital may be given by mouth in amounts of 15, 30 or 60 mg. three times a day, no more being given than will keep the patient free or nearly free of convulsions. If phenobarbital cannot be tolerated, sodium bromide may be used in amounts of 0.3, 0.6 or 0.9 Gm. three times a day. Phenobarbital is best used in amounts not exceeding 60 mg. three times a day. If the patient is still having convulsions under those circumstances, it is recommended that sodium bromide be added to the evening or morning medication.

Sodium bromide has an advantage in that the amount of bromide may be easily determined in the blood. Because of the troublesome delirium that results from excessive ingestion of the drug, bromide should never exceed 125 mg. per hundred cubic centimeters of blood. Bromide has the disadvantage of producing an acne. Sometimes this can be overcome by the use of solution of potassium arsenite (Fowler's solution) given in amounts of 5 drops three times a day.

How to stop treatment: Sedative therapy should not be discontinued completely within two years of the time of the last convulsion. Moreover, it is important never to stop suddenly but always to reduce sedation gradually no matter what its nature.

DR. GOLD: Dr. Gordon will discuss some of the problems that arise in pediatric practice in connection with the treatment of convulsive states.

Convulsions

	Conditions Which May Tend to	
	Prevent Seizures	Precipitate Seizures
Acid-base equilibrium...	Acidosis by means of fasting, fat diet	
	Ingestion of acids or acid-forming salts	Alkalosis by means of ingestion of *alkali*
	Breathing high carbon dioxide	Hyperpnea "blowing off" carbon dioxide
Chemical constituents..	Low chloride	High chloride
	High calcium	Low calcium (tetany)
	Normal sugar	Hypoglycemia
Water balance.....	Dehydration	Edema
Sleep.....	Adequate (8-9 hrs.)	Inadequate—fatigue
Emotions.....	Contentment or satisfaction	Tension, rage, resentment, frustration, boredom
Oxygen.....	Rich supply	Poor supply
Permeability of tissues.	Decreased	Increased
Intracranial pressure...	Decreased	Increased
Intracranial circulation	Unimpaired	Impaired

DR. H. H. GORDON: If called over the telephone to treat an infant or child with convulsions, one may ask the mother to give her infant or child a warm tub bath. It is necessary that the room be warm and the infant may be carefully immersed in water at a temperature of approximately 90 F. for about five or ten minutes. The infant or child may then be taken from the tub and wrapped in warm blankets. There is a great deal of doubt concerning the efficacy of this measure, but it gives the frantic mother something to do while awaiting one's arrival. On arrival, if the infant or child is still having convulsions, it is advisable to administer some sedative, preferably after observing the nature of the convulsion. One may give chloral hydrate in a 5 to 10 per cent solution by rectum, administering from 0.2 to 0.3 Gm. for infants less than 6 months of age and from 0.3 to 0.6 Gm. for infants over 6 months of age, or one may give soluble phenobarbital hypodermically in doses of from 15 to 30 mg. as the initial dose. After administration of the sedative, information may be obtained from the mother and from physical examination which will give a clue to the etiology of the convulsions, and this in turn will guide further treatment.

Convulsions may be divided into several groups according to etiology. First are the convulsions that occur at the onset of acute infections. This represents

the largest group that are seen, and fortunately these convulsions tend to be self limited. As one might expect, it is in this group that one obtains the most salutary effect of the warm tub baths. In the treatment of these children a prominent pediatrician has recommended that the best method of procedure is to drive directly to the patient's home and then three times around the block before parking. By the time one arrives, the convulsion will have subsided. I think that until one learns to know those members of one's clientele that are apt to have convulsions at the onset of fevers it is probably more advisable to go directly to the scene and administer some therapy. Prompt use of antipyretics may prevent the high fevers which are frequently associated with convulsions. At the onset of a contagious disease, such as measles or with meningitis, convulsions may occur which last for three or four hours and do not respond to the customary doses of chloral hydrate or soluble phenobarbital. In such individuals one may have to resort to ether or occasionally to avertin with amylene hydrate given by rectum in doses of approximately 80 mg. per kilogram of body weight.

The second group of convulsions, tetany, are associated with a decrease in the ionized blood calcium. We see these convulsions in infants with rickets, particularly between the ages of 6 and 18 months. Tetany also occurs in younger infants—infants who are less than 3 months of age, and even in the newborn period. In this group there is usually no evidence of rickets, and because, in addition to a low calcium, a high blood phosphorus has been found, it has been suggested that these infants have transient hypoparathyroidism. Tetany occurs in association with alkalosis. When prolonged vomiting has taken place, with loss of chlorides, alkalosis may develop, with resultant decrease in ionization of calcium and symptoms of alkalotic tetany or "gastric" tetany. Finally there are the rare cases of spontaneous or postoperative hypoparathyroidism. In all these subjects the obvious remedy is to increase the blood calcium, and this can be done by the administration of calcium chloride. Usually it is given in a 10 per cent solution in milk, in an initial dose of from 2 to 4 Gm. for infants above 6 months of age, followed by from 1 to 2 Gm. every six hours thereafter. For infants of less than 3 months we give from 1 to 2 Gm. of calcium chloride as the initial dose, followed by 0.5 Gm. every six hours thereafter.

An occasional infant will vomit calcium chloride. One may then give calcium lactate. If calcium lactate is used, one has to give from one and a half to two times as much as of calcium chloride. This is for two reasons: In the first place, calcium lactate has less calcium per gram than calcium chloride. In the second place, calcium chloride is more effective in raising the ionized blood calcium. The chloride ion is absorbed more rapidly than the lactate, producing a tendency toward acidosis, and therefore to increased ionization of whatever calcium is available in the blood stream.

Occasionally one administers calcium parenterally, using calcium gluconate, 10 per cent solution, in doses of from 5 to 10 cc. intramuscularly. In small infants and infants with not very much adipose tissue it has been reported that parenteral calcium has left persistent hard nodules, so that parenteral calcium is not used unless oral administration is impossible because of incessant convulsions. The administration of vitamin D preparations in adequate amounts to prevent rickets has decreased the incidence of tetany. Tetany is now seen more rarely in association with rickets than previously, and more individuals are being reported with the disease in the group of younger infants.

Convulsions occur not infrequently in the newborn period. They may be associated with cerebral hemorrhage. Cerebral hemorrhage may be secondary to birth injury. Under such conditions sedatives are administered in the doses previously mentioned, and if a bulging fontanel exists a lumbar puncture may help reduce the frequency of convulsions. Intracranial hemorrhage may be a manifestation of hemorrhagic disease of the newborn, and if an infant shows a tendency toward bleeding anywhere else, a transfusion which stops the bleeding will stop the convulsions. Convulsions in the newborn may be in association with anoxemia due either to atelectasis or to congenital heart disease. In such infants the administration of oxygen will aid in stopping the convulsions.

In patients with congenital cerebral defects, convulsions may be recurrent, and in these the treatment will follow essentially the principles that Dr. Wolff has outlined for treatment of epilepsy.

Finally, there is one acute specific infection associated with convulsions in childhood, namely tetanus or lockjaw. In the treatment of tetanus excellent results have been obtained by the use of avertin with amylene hydrate in doses of from 80 to 100 mg. per kilogram of body weight, given as often as two or three times a day. Such treatment permits the peaceful administration of serum and parenteral fluids to an individual without inciting convulsions.

DR. GOLD: Dr. Milhorat will continue the discussion.

DR. ADE T. MILHORAT: I may first make a few remarks about some of the agents which have just been considered in the treatment of convulsions. There is a large group of barbituric acid compounds that are used in therapeutics. Their most important action is that of depression of the central nervous system. The degree depends on the size of the dose. Qualitatively their essential effects are similar. Some of the compounds, however, do show significant quantitative differences in potency. It takes more barbital than phenobarbital, for example, to produce similar effects. They also differ with respect to the duration of their action. Some of the barbiturates produce narcosis which may last as long as from twenty-four to forty-eight hours (barbital and phenobarbital); in the case of others, such effects may wear off within about a half hour. On the basis of safety there is little to choose between them, except that in the case of overdosage the more rapidly eliminated compounds provide an advantage. Barbital is eliminated from the body mainly by excretion in the urine. The other barbituric acid compounds that are generally available are, for the most part, broken down in the liver, none of the dose, or at most only a small part of it, being excreted in the urine. In their acid form the barbiturates are insoluble in water and are suitable only for oral administration. The sodium salts, however, are quite soluble and these are employed for intramuscular or intravenous injection. The Pharmacopeia describes the compound Soluble Barbital, which is barbital sodium, and Soluble Phenobarbital, which is phenobarbital sodium.

It should be remembered that the intravenous administration of these drugs is not without danger. Doses large enough to produce general anesthesia should be avoided. In general it would be wise not to exceed one

fourth of the anesthetic dose as the first injection, and additional smaller amounts may be given as necessary. Furthermore, an intravenous injection of these compounds should be made very slowly, since the rapid intravenous injection is likely to produce pronounced fall of the blood pressure. The danger in such cases is, of course, respiratory and vasomotor paralysis.

Ether is useful in controlling violent convulsions and has the advantage of the ease with which the depth of narcosis can be controlled. On the other hand, it requires such constant vigilance that its use becomes extremely difficult in cases in which pronounced depression is necessary over long periods of time.

The bromides have an interesting mode of action. They replace chlorides in all the tissues, which phenomenon appears to be of no particular significance to any but the tissues of the central nervous system. Their accumulation causes depression of the central nervous system, which varies with the dose. As one might expect, their excretion is hastened by the administration of chlorides. So it is well to limit chloride intake in order to maintain protracted bromide effects. There is no real difference between the sedative action of the various bromides, such as sodium, potassium or calcium bromide. On the whole, sodium bromide is perhaps preferable because the potassium ion is more toxic. One of the disadvantages of continued administration of the bromides is the rather frequent occurrence of acne.

Avertin with amylene hydrate is used by rectal instillation, has the advantage of being rapidly absorbed in that way, and in moderate doses of the order of about 40 mg. per kilogram produces fairly satisfactory and safe depressant effects. It is eliminated by the kidneys. This fact must be taken into account when its use is contemplated in patients with impaired renal function.

Chloral hydrate is among the older hypnotics and is not so popular at the present time. Its toxic effects are similar to chloroform and it is therefore unsuited for protracted administration. It is too irritant to be given in tablet form. Its solutions are also quite irritant and its taste is not pleasant. It is best given dissolved in a vehicle, such as aromatic elixir, and should be well diluted. It may also be given by rectum. It is eliminated by excretion in the urine in an altered form in combination with glycuronic acid.

In the short time remaining, I may say a few words regarding the treatment of convulsions due to poisoning by drugs, such as the local anesthetics, strychnine, camphor and picrotoxin. These all may cause death by paralysis of respiration, but the paralysis is not produced in the same way in all cases. We should keep this in mind in our treatment. The barbiturates can abolish the convulsions caused by cocaine, and this is useful because the convulsions have a damaging influence on respiration. It appears to be necessary to abolish the convulsions to afford protection. But it is an easy matter to do harm with the barbiturate because cocaine itself directly depresses the respiratory center and so do the larger doses of antidote. The case of strychnine convulsions is different. Strychnine causes increased reflex excitability, which fatigues the respiratory center as shown by Gold and Travell, and this hyperexcitability of the center rather than the convulsions plays the major role in causing cessation of respiration. Therefore depressant drugs, such as the barbiturates, ether or alcohol, can prevent the respiratory depression of strychnine even when they fail to abolish the convulsions. From the practical standpoint it is wise to maintain a state of moderate hyperexcitability in strychnine and cocaine poisoning so as to avoid overdosage with the depressant.

DR. GOLD: I am sorry to have to cut short the direct discussion. We should like to have as much time as possible for questions.

STUDENT: In a series of patients coming in with epileptic seizures, about what percentage have an organic lesion that can be demonstrated by the encephalogram or other diagnostic procedure?

DR. WOLFF: You are leaving out of consideration the group that have brain lesions that cannot be demonstrated by our available methods?

STUDENT: Yes.

DR. WOLFF: I am guessing, but I would say between 10 and 15 per cent have lesions that can be demonstrated with our available methods.

STUDENT: How effective is magnesium sulfate in the treatment of convulsions, particularly in the eclamptic?

DR. WOLFF: Very effective. I have left it out of my discussion because the agents I referred to probably have the most behind them in the way of experience. Magnesium sulfate is an excellent drug and may be used if you happen to like it. There is nothing against it.

STUDENT: Would you say something about the care of the tongue in convulsions?

DR. WOLFF: Most people do not need anything done to their mouths during a convulsion. The tongue usually falls back and out of the way of the teeth, yet it does not fall back far enough to cause asphyxia. As you look at the patient during a convulsion, keep "an eye" on the mouth, and color, but look especially for evidence that might be useful in localizing a lesion. Usually you are not called on to do anything more active than to sit at the side of the patient and prevent him from hurting himself, assuming the patient does not have a destructive or dangerous delirium. Moreover, you need seldom do anything about the tongue. It will take care of itself.

Was there some special aspect I did not touch on?

STUDENT: Yes, how about gags?

DR. WOLFF: The gag is a vicious instrument in my opinion. It is made of one or two tongue depressors held together with a piece of adhesive plaster on one end. The patient has this end put between the teeth, preferably between those in back. It is hoped that the teeth will close down on it. What often happens is that somebody has to force the jaws apart in order to get the gag in place. I do not think the apparatus is useful. If the tongue has already been caught between the teeth, the injury has been done.

DR. MILHORAT: May I ask Dr. Gold a question? What is your feeling regarding the use of paraldehyde in convulsions? The drug is used very little, yet it would appear to be a relatively safe drug.

DR. GOLD: Perhaps paraldehyde ought to be used more commonly than it is, although it does possess a very disagreeable odor. It can be given in large doses with safety. There are some interesting reports on the use of paraldehyde in obstetric analgesia; in one of these they used doses of the order of 8 drachms (30 cc.) of paraldehyde by rectal instillation together with 1.5 cc. of benzyl alcohol to reduce the effects of the irritant action of the paraldehyde on the rectum.

Smaller doses have been repeated as necessary during the day, and they appeared to be both effective and safe.

DR. J. E. DEITRICK: Is the action of paraldehyde by rectum as rapid as soluble phenobarbital intravenously? In a patient coming into an accident room with convulsions, isn't it difficult to insert a rectal tube and give paraldehyde in that way?

DR. GOLD: I quite agree. On the other hand is it not just as difficult to make an intravenous injection of soluble phenobarbital during convulsions? A subcutaneous or intramuscular injection is, of course, much easier but the effects are delayed.

DR. DEITRICK: I should like to ask another question about paraldehyde while we are on the subject. Would you recommend its being given intravenously? I had it given intravenously in two cases with striking therapeutic effects.

DR. GOLD: Paraldehyde has been used intravenously, and I see no reason why it cannot be given intravenously. One should be certain of its purity, since ordinary commercial samples often contain significant amounts of acetaldehyde. The dose is about 4 cc. in a 10 per cent solution of physiologic solution of sodium chloride.

Are there any other questions?

STUDENT: Should the occasion arise in a digitalized patient in which it is necessary to give large doses of calcium, is there any contraindication for its use?

DR. GOLD: No, there is no absolute contraindication, but it ought to be given more cautiously because of the possibility that a fully digitalized subject may be more susceptible to calcium. The fear of the combination arises chiefly from experiments in animals. These show a synergism between the two drugs when toxic doses of each are given. Recent experiments in our laboratory, however, show no serious effects of the combination when both drugs are given in amounts comparable to even the highest amounts used therapeutically.

STUDENT: I should like to ask Dr. Gordon what other procedures are used in children with laryngeal spasm during the convulsion.

DR. GORDON: Occasionally laryngeal intubation will be used, if the oral, intramuscular or intravenous administration of calcium has not relaxed the laryngospasm. This is very rare.

DR. MILHORAT: A great deal is said about the occurrence of skin rashes in patients who are given phenobarbital, but isn't it a fact that in the large series of patients with epilepsy who are treated in our neurologic clinic with continued administration of phenobarbital these have occurred only in probably one or two instances?

DR. WOLFF: Yes, cutaneous manifestations are uncommon in our series of patients with convulsions.

STUDENT: Could I ask Dr. Wolff about the present evaluation of ketogenic diets in epileptic seizures.

DR. WOLFF: They are expensive and inconvenient for the patient. There are instances in which the ketogenic diet is found to be useful.

STUDENT: You mean you would use it after trying the other methods?

DR. WOLFF: My own practice is to reduce the fluids to between 500 and 800 cc., to have the patients take a diet which approximates two calories of fat to one of carbohydrate, which is not a ketogenic diet, but one which is not so expensive or not so inconvenient. The total calories are 2,600. In addition, I give phenobarbital, starting with 15 mg. three times a day, and raise it 15 mg. per dose daily until I get the desired effect. In short, I use an eclectic method.

DR. GOLD: I believe it was stated here that the adult during a convulsion is given a dose of 60 mg. of phenobarbital, and Dr. Gordon gives an infant a dose of 30 mg. Infants may then receive as much as one half of the dose given to adults. If the weight of the infant is taken at about 30 pounds and Dr. Wolff's adult at about 150 pounds, the infant receives 2.5 times as much as the adult on the basis of their weights. Is the infant more tolerant to phenobarbital than the adult, or is the dose larger than necessary for infants? That is the first question. The second is: Why does phenobarbital receive preference over other barbituric acid compounds? Do you believe it more effective or safer?

DR. WOLFF: One assumes that patients will take some sedative drug for years. Certainly 60 mg. three times a day is probably not the limit of tolerance of a patient, but when you appreciate that the drug is going to be taken daily for years in amounts of 180 mg. it does seem to be about as much as should be given.

DR. GOLD: From experiences I have had, I believe children commonly receive excessive doses of sedatives. As to adults, suppose that 1 grain three times a day is not adequate to control the convulsions; is it not all right to give them 2 or even 3 grains?

DR. WOLFF: I dare say. If 60 mg. three times a day is inadequate, I prefer to supplement the drug with bromides, i. e. 60 mg. of phenobarbital three times, plus whatever additional bromide is necessary. From a toxicologic standpoint it would probably be reasonable to give greater amounts of phenobarbital if desired.

STUDENT: Why phenobarbital and not some other barbituric acid compound?

DR. WOLFF: It just happens to be one that has behind it a tradition of use. It is an agent that I happen to have more experience with than any other. It is a relatively inexpensive form of barbiturate, and its action is moderately prolonged. I think there is no other justification. I feel there are probably other barbiturates that would be quite as good if one happened to have a similar amount of experience with them.

DR. MCKEEN CATTELL: Doesn't your statement about the barbiturates apply to other sedatives as well? Isn't the selection of different sedatives in various conditions to a large extent a matter of fortuitous experience with certain compounds rather than a matter of superior merits of one over another?

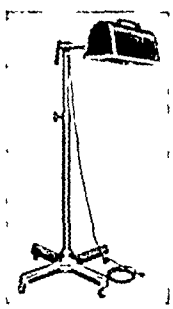
DR. WOLFF: I think that is correct.

DR. GOLD: Are there any other questions?

Avertin with amylene hydrate was recommended for the control of convulsions in doses of from 80 to 100 mg. per kilogram. The literature reports deaths from avertin with amylene hydrate used in doses of the order of 120 mg. per kilogram, and I am wondering whether one is not likely to get into trouble from time to time with such doses as from 80 to 100 mg.

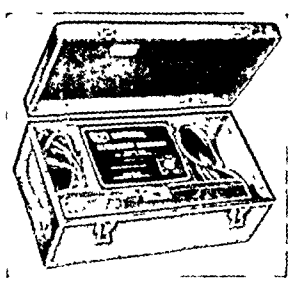
DR. GORDON: My experience with the use of avertin with amylene hydrate in doses of from 80 to 100 mg. has been limited to several patients with tetanus, to whom it was given for as many as fourteen continuous days without difficulty, and with great relief of symptoms. Further experience might make for more cautious recommendations.

Council on Physical Therapy



THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

HOWARD A. CARTER, Secretary.



LIEBEL-FLARSHEIM GENERAL BODY QUARTZ LAMP AND ORIFICIAL ULTRA-VIOLET GENERATOR ACCEPTABLE

Manufacturer: The Liebel-Flarsheim Company, 303 West Third Street, Cincinnati.

The Liebel-Flarsheim General Body Lamp and Orificial Lamp are of the so-called "cold" type of mercury glow quartz ultraviolet generators. They are low pressure, low temperature

Liebel-Flarsheim General Body Quartz Lamp.

Liebel-Flarsheim Orificial Ultraviolet Generator

burners. One burner is intended for general body irradiation, the other a quartz tube for orificial application. The general body type has a self-contained head, including burner and transformer, and adjustable stand. It is finished in crinkled black lacquer with chrome plated metal trim. The detachable head is equipped with a handle for transportation. When used with the stand, it may be rotated through a circle or extended 18 inches toward the side and then rotated. It is adjustable in height from 34½ to 63½ inches. The head is spring counter-

Apparent Relative Photographic Intensity of L-F General Body Quartz Lamp No. V-101 June 9, 1938

Wavelength Angstroms	Log_{10} I	I
2,536	3.25	1,780
2,650	0.65	4.5
2,804	0	1.0
2,894	.40	2.5
2,967	1.05	11.2
3,022	.73	5.4
3,130	1 80	63.

balanced for ease of adjustment. The whole is mounted on rubber tired, ball bearing casters with supporting feet heavily weighted to prevent tipping.

The professional type burner is placed in front of the transformer in the hood. This avoids exposure of the patient to contact with high voltage leads. The transformer delivers 2,000 volts on open circuit. The current to the burner under full load is 18 milliamperes. A 5 foot quartz tube burner is arranged in rectangular grid, evacuated and filled with gas and liquid mercury. It will produce a first degree erythema after two minutes' exposure at a distance of 20 inches, according to the firm.

The Liebel-Flarsheim General Body Lamp has a 26 watt input at 115 volts, 60 cycles; after it is run for some time, until stable, it has 138 microwatts per square centimeter output at a distance of 20 inches measured from the centers of the tubes for all wavelengths less than 3,200 angstroms. Over 95 per cent of the energy is concentrated at 2,536 angstroms (measured in air).

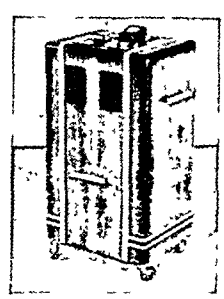
The relative values of the intensity of the lines are given in the accompanying table. The absolute measurements were made with a calibrated thermopile.

The orificial unit is supplied in a keratol-covered carrying case, which houses the transformer and also accommodates the separate burner case, the orificial applicator and supply cable. It operates on 110 volt, 60 cycle, alternating current outlet. The orificial lamp consists of a quartz tube of a fairly orthodox shape and size, held in a molded bakelite handle. The transformer delivers about 2,000 volts on open circuit; on full load the current to the lamp is 10 milliamperes. An orificial applicator of universal size to facilitate treatments to accessible orifices is supplied.

The ultraviolet output is constant and capable of producing a first degree erythema in approximately ten seconds on contact application to the skin, according to the firm. On a patient with extremely hypersensitive skin this time is reduced to about five seconds.

The output of the orificial lamp at 1 inch distance with 1 inch of tube exposed and the rest covered is 3,280 microwatts per square centimeter. The input is 9 watts at 115 volts, 60 cycles, the lamp being run until stable before measuring.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Liebel-Flarsheim General Body Quartz Lamp and Orificial Ultra-Violet Generator for inclusion in its list of accepted apparatus.



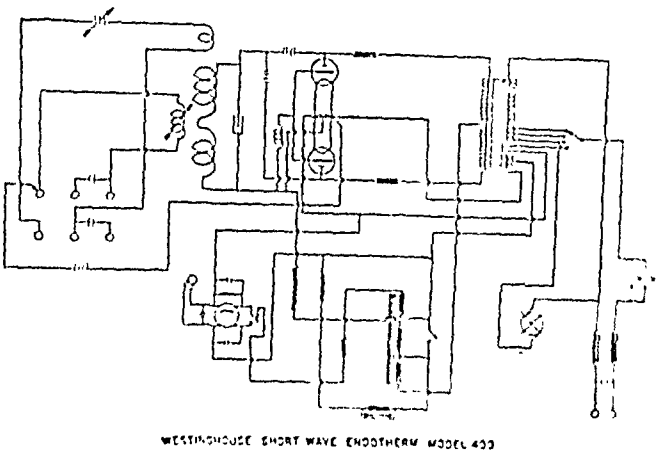
WESTINGHOUSE SHORT WAVE ENDOTHERM, MODEL 400, ACCEPTABLE

Manufacturer: Westinghouse X-Ray Company, Inc., Long Island City, N. Y.

The Westinghouse Short Wave Endotherm, Model 400, is recommended for medical and minor surgical purposes. It is housed in a dark walnut cabinet. Pad, cuff and cable electrodes and felt spacers are part of the standard equipment. A treatment drum with floor stand is available. Surgical accessories may be procured for minor surgical procedures commonly employed in office practice. The instrument panel has two separate controls, one for pad, cuff and surgical procedures and one for the coil technic. There are six patient outlets, a power output meter and main switch to operate tubes, and forced draft ventilating fan.

The tubes are employed in a tuned plate, tuned grid circuit. The wavelength is 22.4 meters. Both the cable and pad circuits are inductively coupled to the oscillator circuit. For surgery there is a separate terminal receiving its energy through a small fixed condenser. A voltage regulator is supplied to compensate for the variations in the voltage of the supply line.

After four hours of continuous operation, the temperature rise in the outside windings of the transformer was 50 C. The power input under full load showed a maximum of 1,140 watts. A power output of 400 watts by the lamp load method claimed by the firm was verified. The tubes are protected against overload by a safety regulator.



Westinghouse Short Wave Endotherm, Model 400.

In order to substantiate heating claims made for the unit, the firm submitted tests performed by a qualified investigator. Details are given here:

Two male subjects, weighing 190 and 195 pounds respectively, were used in these tests. Twelve observations were taken, six with the inductive method and six with the double cuff technic. The technical procedure for making the tests was that recommended by the Council. A cannula was introduced at the midpoint of the thigh and inserted for a distance of 2 inches or until the femur was encountered. Temperature readings were made by means of thermocouples inserted into the cannula and constructed of constantan and copper placed in hypodermic needles. The constant junction was kept at 0 C. by placing in a vacuum bottle filled with crushed ice. The couples were calibrated in a constant temperature oil bath against a mercury thermometer certified and

calibrated by the National Bureau of Standards. Potential differences were read from a Leeds and Northrup portable potentiometer of requisite sensitivity. The accuracy is within plus or minus 0.1 degree F.

WESTINGHOUSE SHORT WAVE ENDOTHERM MODEL 400

Schematic diagram of circuit.

For the coil technic three turns of the cable around the thigh were employed, equally spaced by a wooden holder. It was approximately 5 inches from the upper to the lower edge of the cable. A spacing between the cable and skin of three-fourths inch was achieved by felt and one layer of toweling. The cannula was spaced between the outside turns of the cable. Then the machine was operated to the tolerance of the patient.

When the cuff technic was used, these electrodes were 15 inches by 3¼ inches in diameter. They were applied equidistant above and below the cannula and averaged from 7½ inches to 9¼ inches center to center. Felt spacing, from one-half to three-fourths inch, was placed between the skin and the cuff.

Six tests were also run with the treatment drum technic. The electrode was applied over the thigh as close to the skin and nearly over the point where temperatures were read as the inserted thermocouples would permit. The patient's tolerance to heat on the skin was the control of intensity of current.

Orificial tests were run to indicate the amount of pelvic heating available with this unit. Temperatures were taken for this treatment with a large Chapman electrode. This was drilled through so that the thermometer could be passed and the mercury bulb brought into contact with cervical tissue. A large short wave pad was used as the dispersive electrode. This was spaced approximately 3 inches from the lower abdomen by means of a folded turkish towel. The thermometer was left in place throughout the treatment.

The unit was tried out clinically by a reliable investigator, who reported that it operated satisfactorily.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Westinghouse Short Wave Endotherm, Model 400, for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

PAUL NICHOLAS LEECH, Secretary.

RACÉPHEDRINE (RACEMIC EPHEDRINE), RACÉPHEDRINE HYDROCHLORIDE (RACEMIC EPHEDRINE HYDROCHLORIDE) AND RACÉPHEDRINE SULFATE (RACEMIC EPHEDRINE SULFATE)

The manufacturer of a brand of synthetic racemic ephedrine hydrochloride asked the Council to adopt a nonproprietary name. The Committee on Nomenclature voted that the name Racéphedrine be recognized as a nonproprietary designation for the racemic ephedrine base and that Racéphedrine Hydrochloride be the name for racemic ephedrine hydrochloride. The Council voted to include Racéphedrine Hydrochloride in New and Nonofficial Remedies. The Council has under consideration Racéphedrine and Racéphedrine Sulfate.

DANGER OF INTRA-URETHRAL INJECTION OF SOLUTIONS OF LOCAL ANESTHETICS

The Council has again considered a report on local anesthetics, particularly in reference to the continued reports of severe reactions following the intra-urethral injection of solutions of various local anesthetics.

The Council has long warned against the danger of such procedures. In the report of the Committee for the Study of Toxic Effects of Local Anesthetics (THE JOURNAL, March 15, 1924, p. 876) it was pointed out that "Urethral injections constitute a special source of danger. Absorption does not take place readily from the bladder or bronchial mucous membrane." It was recommended that solutions of "local anesthetics should not be injected into the urethra when trauma or stricture exists." In spite of these warnings, however, the attention of the Council office is being called more or less frequently to recurrences of toxic effects due to intra-urethral injection of solutions of local anesthetics. It was pointed out in the Council consideration that in this type of tragic accident often the occurrence is wholly unexpected and it may follow the injection of a much smaller amount than the same patient had previously had without notable symptoms. It therefore seems advisable to repeat the warning as to the use of local anesthetics intra-urethrally.

The Council directed that all manufacturers of Council accepted local anesthetics which may be used for intra-urethral injection be required to include a suitable warning of the dangers of the intra-urethral injection in the presence of trauma, or where it is likely to occur at the time of injection, when the present advertising is reprinted, and in any event within one year of the date of notification.

PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

YELLOW BONE MARROW CONCENTRATE (THE ARMOUR LABORATORIES)

In 1934 Armour and Company presented Yellow Bone Marrow Concentrate, stated to be "a concentrated oily solution of the physiologically active substances which promote the formation of granulocytes and are present in the yellow bone marrow of cattle and other domestic animals used for food by man." It is proposed for use in agranulocytosis.

The firm submitted a number of case reports collected by the Sprague Memorial Institute and the Department of Pathology of the University of Chicago and stated that reports were being prepared for publication. Reference was made to the paper of Griffin and Watkins which appeared in THE JOURNAL, Aug. 23, 1930, page 587. At that time the firm was informed that the Council could not report satisfactorily on the product because of *the paucity of clinical evidence.*

Since that time the consideration was held in abeyance until the firm in 1938 reopened the matter and submitted reprints of two articles (Marberg, C. M., and Wiles, H. O.: Granulocytopoietic Fraction of Yellow Bone Marrow, *Arch. Int. Med.* **61**:408 [March] 1938 and Marberg, C. M., and Wiles, H. O.: Yellow Bone Marrow Extracts in Granulocytopenia, THE JOURNAL, Dec. 11, 1937, p. 1965).

The Council's referee reviewed this evidence carefully and summarized the situation as follows:

1. The beneficial effect of Yellow Bone Marrow Concentrate (The Armour Laboratories) has been evidenced in six cases of what seems to be true agranulocytic angina. Clinical improvement including increase in neutrophils followed the administration of this substance.

2. While this clinical evidence leaves something to be desired, it is recognized that the difficulty in securing cases is real.

The Armour Laboratories was asked to make certain revision of its proposed advertising for the product and did so. The Council felt, however, that the evidence was not sufficient to warrant acceptance at this time and voted to hold consideration in abeyance pending the development of future corroborative evidence for the place of Yellow Bone Marrow Concentrate in the treatment of agranulocytosis, meanwhile authorizing publication of the foregoing preliminary report.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

RACÉPHEDRINE HYDROCHLORIDE. — Racemic Ephedrine Hydrochloride. — *d-l*-Ephedrine Hydrochloride. — $C_{10}H_{17}ON.HCl$.

Action and Uses.—The same as those of l-ephedrine hydrochloride.

Dosage.—From 30 to 50 mg.

Racéphedrine hydrochloride (Synthetic racemic ephedrine hydrochloride) is a colorless, crystalline substance. The melting point of crystalline racéphedrine hydrochloride is 187-188 C. (microscopic heating stage). The solubility in water is 1 part of substance in 4 parts of water at 20 C; in alcohol, 1 part of substance in 25 parts of 95 per cent ethyl alcohol. The aqueous solution is neutral to litmus.

Weigh out, accurately, 0.2 Gm. of racéphedrine hydrochloride and transfer over phosphorus pentoxide in an Abderhalden dryer at 80 C., exhaust to 2 mm. of mercury vacuum and dry for five hours: the loss of moisture is not more than 2 per cent. Incinerate 0.2 Gm. of racéphedrine hydrochloride, accurately weighed, and previously dried to constant weight, as described: no residue remains. Dissolve approximately 0.5 Gm. in 20 cc. of water: the aqueous solution of racéphedrine hydrochloride does not show optical activity; the solution gives the test for chlorides, U. S. P. XI, page 449; on addition of ammonia water or sodium carbonate solution, no turbidity takes place. Slightly acidify 3 cc. of the solution with diluted hydrochloric acid (0.5 cc.): no precipitate occurs on the addition of barium chloride solution (0.5 cc.) *(sulfates).*

Dissolve approximately 0.02 Gm. of racéphedrine hydrochloride in 1 cc. of concentrated sulfuric acid: no color is formed. To approximately 0.2 Gm. dissolved in 1 cc. of distilled water add 2 cc. of 20 per cent sodium hydroxide solution: oily drops are formed. Extract the milky turbid mixture twice with 25 cc. of ether: the (racéphedrine) base crystallizes out on slow evaporation of the ether; after recrystallization from ether and drying at room temperature over phosphorus pentoxide in a slight vacuum, the racéphedrine melts at 76 C.

Dissolve approximately 0.2 Gm. of racéphedrine in 8 cc. of distilled water; add 1 drop of 2 per cent copper sulfate solution and 1 cc. of 20 per cent sodium hydroxide solution: a purple color is developed which, on shaking with ether, is partially dissolved in the ether layer; evaporate the ether layer: a pinkish residue remains. Place a drop of a 5 per cent solution of racéphedrine hydrochloride on a microscopic slide and introduce a small solid particle of potassium oxalate at an edge of the drop: a crystalline precipitate immediately appears. The form of the crystals allows the making of distinction between optically active and racemic forms of ephedrine hydrochloride. The former gives bundles of needles and prisms; the latter, thin plates.

Transfer 0.5 Gm. of racéphedrine hydrochloride, accurately weighed and previously dried over sulfuric acid for five hours, to a separator. Add 10 cc. of distilled water and 5 cc. of ammonia solution. Extract with 6 portions of ether, using 25 cc., 20 cc., 15 cc., 15 cc. and 15 cc., respectively. Collect the extracts in a beaker; evaporate the ether on a water bath to about 5 cc.; add 10 cc. of alcohol, previously neutralized to bromthymol blue solution with 0.1 normal hydrochloric acid. Titrate the excess acid back with 0.1 normal sodium hydroxide: the racéphedrine (base) found is not less than 80 per cent nor more than 82.5 per cent of the weight of racéphedrine hydrochloride. (One cc. of 0.1 normal hydrochloric acid is equivalent to 0.0165 Gm. of racéphedrine.)

IMMUNE GLOBULIN (HUMAN) (See THE JOURNAL, Nov. 5, 1938, p. 1767).

National Drug Company, Philadelphia.

Immune Globulin (Human).—Prepared by the method of McKhann from fresh, healthy human placentas; the globulin is reprecipitated to reduce the content of other tissue proteins and hemoglobin. Merthiolate 1: 4,000 is added as a preservative. Each lot is tested for sterility by the method of the National Institute of Health. Marketed in 2 cc. and 10 cc. glass syringes with chromium steel needles for parenteral use.

RABIES VACCINE (See New and Nonofficial Remedies, 1938, p. 402).

Medical Arts Laboratory, Inc., Oklahoma City.

Rabies Vaccine (Killed Virus): Also marketed in packages of seven vials, each vial containing 2 cc.

NICOTINIC ACID (See THE JOURNAL, July 2, 1938, p. 27, and the Revised Supplement to N. N. R. 1938, p. 22).

Mead's Nicotinic Acid Tablets, 20 mg.

Prepared by Mead Johnson and Company, Evansville, Ind. No U. S. patent or trademark.

Nicotinic Acid-Abbott.—A brand of nicotinic acid-N. N. R.

Manufactured by the Abbott Laboratories, North Chicago, Ill. No U. S. patent or trademark.

Nicotinic Acid Tablets, 50 mg.-Abbott.
Nicotinic Acid Tablets, 100 mg.-Abbott.

STOVARSOL (See New and Nonofficial Remedies, 1938, p. 100).

The following dosage forms have been accepted:

Stovarsol Tablets, 0.1 Gm.
Stovarsol Tablets, 0.05 Gm.

ESTRONE-ABBOTT (See THE JOURNAL, Oct. 1, 1938, p. 1301, and Revised Supplement to New and Nonofficial Remedies 1938, p. 12).

The following dosage form has been accepted:

Ampoules Estrone, 0.5 mg. in oil, 1 cc.: Each cubic centimeter contains estrone 0.5 mg. (5,000 international units) in sesame oil.

IODEIKON (See New and Nonofficial Remedies, 1938, p. 218).

The following dosage form has been accepted:

Iodeikon Emulsion Powder-Abbott.—Iodeikon 33.34 per cent in a vehicle composed of malt sugar 37.30 per cent, powdered cocoa 18.30 per cent, tartaric acid 8.25 per cent, vanillin 2.20 per cent, saccharine 0.54 per cent and menthol 0.07 per cent.

Prepared by the Abbott Laboratories, North Chicago, Ill.

DIGITALIN, "GERMAN" (See New and Nonofficial Remedies, 1938, p. 191).

Hypodermic Tablets Digitalin (German, Pure, Merck), 0.00065 Gm. 1/100 grain-Upjohn.

Prepared by The Upjohn Company, Kalamazoo, Mich. No U. S. patent or trademark.

OLD TUBERCULIN (See New and Nonofficial Remedies, 1938, p. 408).

Eli Lilly & Co., Indianapolis.

Tuberculin Ointment (Wolff)-Lilly.—A culture of human tubercle bacilli (H-37) of four weeks' growth in glycerin broth, sterilized, evaporated to one-fifteenth its original volume and triturated to a smooth mixture, to which 0.4 per cent of phenol is added as a preservative. *It is proposed for* use as a tuberculin test by the patch method. Marketed in packages of one 2 Gm. collapsible tube with a 2 Gm. control tube.

A NEW DIETARY FACTOR

Failure of nicotinic acid to prevent pellagra-like symptoms in rhesus monkeys, and the successful prevention of rhesus pellagra by a wholly unknown nutritional factor, recently reported by Day,[1] Langston[2] and others of the University of Arkansas, call attention to the possibility that there may be more than one etiologic type of pellagra. About three years ago the Arkansas biochemists placed monkeys on a presumably adequate diet containing all known vitamins. This diet consisted of a mixture of casein, polished rice, ground whole wheat, cod liver oil, ascorbic acid, salt mixture and sodium chloride. All monkeys fed this diet developed anemia, leukopenia, gingivitis, diarrhea, anorexia and loss of weight. The ulcerations of the gum were apparently identical with the typical oral lesions in human pellagra. Death invariably occurred in from one to three months.

Following the well confirmed successes of nicotinic acid in preventing black tongue in dogs, nutritional panmyelophthisis in rats and human pellagra, the Arkansas investigators tested the effects of the addition of nicotinic acid to their routine deficiency diet. From 10 to 50 mg. of nicotinic acid was added to the daily diet. All normal monkeys whose deficiency diet was thus supplemented with nicotinic acid developed the characteristic oral lesions and nutritional cytopenia, the condition terminating fatally in the same period as that shown by control monkeys receiving only the deficiency diet. The nicotinic acid had no demonstrable effect on the pellagra-like oral lesions in these animals. In later tests the Arkansas physiologists found that 1 mg. of riboflavin added to the daily diet will not prevent the development of pellagra in monkeys, nor will a combination of nicotinic acid, riboflavin and thiamin appreciably affect the course of this deficiency disease. If the daily deficiency diet is supplemented by 10 Gm. of dried brewers' yeast, however, or by 2 Gm. of liver extract, normal body growth and a normal blood picture are maintained over long periods.

They conclude from these results that monkeys require some factor contained in yeast or in liver extract in addition to the factors commonly recognized as part of the vitamin B complex. For this unknown nutritional factor they tentatively suggest the name "vitamin M." Attempts to isolate and identify this new antipellagra "vitamin" are now in progress in their laboratory.

THE TENTH PAN AMERICAN SANITARY CONFERENCE

The interest, enthusiasm and occasional criticism aroused by the eighth International Conference of American States at Lima, Peru, last December offer opportunity to point out that when effective Pan American cooperation in most matters was still a dream of statesmen and scholars it had already been achieved in the field of public health, largely under medical auspices. International cooperation of the American republics in this field began at the quarantine conference held in Washington in 1881. There Finlay first enunciated guardedly his hypothesis that the stegomyia mosquito was the vector of yellow fever, then causing one epidemic after another from the United States to Argentina and Chile. When finally this concept was confirmed in 1900 by the American army commission headed by Reed, control methods were revolutionized and yellow fever was eradicated from all its old foci at seaports.

The Pan American Sanitary Conferences[1] came into being as a result of the foresight of such physicians as Finlay himself, Wyman, Liceaga, Guiteras, Ulloa, Cruz and Moore. They were actually created by virtue of a resolution adopted by the second International Conference of American States in Mexico City (1901-1902). Permanent organization both of the conferences and of the Pan American Sanitary Bureau was effected at the first International Sanitary Conference of the American Republics in Washington in October 1902.

The aims pursued by the originators of these meetings are reflected in the remarks of President Theodore Roosevelt to the members of the second conference (1905):

> I believe that we on this hemisphere are going to teach all the world by an object lesson that separate nations can dwell together in absolute harmony and can unite in a common effort, as you are uniting here, for the betterment of the conditions affecting them all. In medical matters, in industrial, scientific, social, artistic matters, each of our countries has something to learn from the others, and I welcome you as colleagues and as teachers. Of course, I could not overstate the all-importance of the medical profession in modern life and, as it is now becoming, in modern international life. In the old days a plague that happened in one country was regarded as only concerning that country until it spread over into some other helpless nation to defend itself against it. Now we recognize that the stamping

1. *Publications on the history* and achievements of the Pan American Sanitary Conferences may be secured by addressing the Pan American Sanitary Bureau, Washington, D. C.

out of disease, the warfare against unhygienic conditions, must be done by the organized effort of the medical profession of all the countries joined together.[2]

At the tenth conference Dr. Hugh S. Cumming said that each of these conferences, held at different capitals of American republics, has left behind it a series of concrete accomplishments which have inevitably advanced the great cause which brought about their organization, namely the improvement of public health in all the American republics through international cooperation so far as this is practicable and advisable. The first Pan American Sanitary Conference (1902) set the standard for the succeeding ones and established the Pan American Sanitary Bureau; the second (1905) formulated the Washington Convention, which was in effect the first Pan American Sanitary Code; the third (1907), fourth (1909-1910) and fifth (1911) consolidated the territory gained and opened new paths for the future; the sixth (1920) provided for the publication of the *Boletín*, which has come to be one of the most important as well as one of the best known activities of the Sanitary Bureau; the seventh (1924) approved the Pan American Sanitary Code, a model international health charter enjoying the distinction of being the first Pan American treaty unanimously ratified by all the republics and of serving as a standard for subsequent international agreements on the same subject; the eighth (1927) and ninth (1934) charted new courses and expanded the functions of the Pan American Sanitary Bureau to the magnitude they have reached. The tenth maintained in full this splendid tradition, imposing new duties on the bureau and recommending new ways of Pan American cooperation.

The problems faced by international public health workers and discussed by them at sanitary conferences have been of pressing importance since the earliest days. Yellow fever was a grave problem confronting the 1881 conference; it was still a problem at the 1938 conference because, while stringent control measures have practically eliminated it from ports and cities and from the danger of maritime transmission, the presence of jungle yellow fever in certain areas combined with the increase of air travel renders this ancient enemy still a possible menace. As the great international scourges of former years—cholera, plague, smallpox, typhus—are brought under control, the importance of other problems comes to light. Malaria, venereal diseases, intestinal parasites, tuberculosis, leprosy, water supply and sewage disposal, milk supply, nutrition, mother and child welfare, social insurance, bacteriologic and biologic standards and similar matters now appear on the programs of the Pan American Sanitary Conferences and the Pan American Conferences of National Directors of Health, the latter also held under the auspices of the bureau.

The tenth Pan American Sanitary Conference was not only successful but also made history along several lines: through the completeness of its program; through the size and technical character of the delegations attending; through the presence for the first time of women delegates; through the extensive scientific reports submitted there both by the various countries and by the Rockefeller Foundation and the Pan American Sanitary Bureau, which permitted the formation of an exact idea of the developments which have taken place since the previous meeting and the progress already achieved or now under consideration;[3] through the enthusiasm which inspired those in attendance; through a health exhibition which so far had never been a feature of these assemblies; through the unanimity of sentiment on the part of the representatives of Pan American public health in the face of questions considered, some of them of the greatest importance; and through the sensible and very practical judgment which, as a rule, guided the discussions.[4] Only one republic (Paraguay) was unable to send representatives. The directors of health of the majority of the twenty-one republics were present, and with them professors of hygiene and experts on such varied themes as bacteriology and biology, venereology, dietetics, tropical medicine, pediatrics and puericulture, tuberculosis, maritime and aerial quarantine and, finally, public health teaching and health administration in general.

The Pan American Sanitary Bureau,[5] which has its headquarters in Washington, D. C., has been a constantly increasing force in international public health since its reorganization in 1920. It maintains traveling representatives, including physicians and sanitary engineers, who visit the various republics from time to time at the request of the national authorities to lend their advice and assistance in dealing with public health problems such as health administration, plague, water supply and sewage disposal, and mosquito surveys; it acts as a consulting agency, publishes a monthly bulletin of public health information with articles in the four official languages (Spanish, French, Portuguese and English), with a circulation of about 9,000 in Latin America, as well as weekly statistical reports and transactions of Pan American Sanitary Conferences, and has a library including more than 400 medical and public health journals from Latin America. The tenth Pan American Sanitary Conference approved several amendments to the constitution of the bureau, one of them recommending an increase in the maintenance quotas to permit the expansion of activities recommended by international public health interest as well as by the Conference for the Maintenance of Peace, Buenos Aires, 1936, and previous sanitary conferences. This increase

Surgeon **83**: 1 (July) 1938; Report to Tenth Pan American Sanitary Conference; Annual Report of the Director, Pan American Sanitary Bureau, 1938.

was also recommended by the eighth International Conference of American States in December, and several countries have already ratified the proposal.

The director of the Pan American Sanitary Bureau, Dr. Hugh S. Cumming, Surgeon General, Retired, U. S. Public Health Service, who has served as director of the bureau since 1920, was present at the conference and for the fourth time was reelected to that position, heading the directing council, each member of which belongs to a different republic. The eleventh Pan American Sanitary Conference is scheduled to be held in Rio de Janeiro, Brazil, in about four years and will be preceded by the fourth Pan American Conference of National Directors of Health, to be held in Washington in 1940.

The American Medical Association lent effective and practical support to this movement through the publication of its Spanish Edition for a period of ten years (1918-1928).[6] Congress has now under consideration the recommendations made by an interdepartmental committee appointed by the President for extending Pan American cooperation, especially in cultural fields, including medicine and public health. Such cooperation does much to establish good will and to overcome prejudices founded on ignorance.

Current Comment

PREVENTION OF SERUM SICKNESS

The "induced erythema" reported by Voss and Hundt[1] of children's clinic in Heidelberg, Germany, is interesting. Blood was drawn from patients convalescent after the serum sickness which in their hands so often follows routine administration of diphtheria antitoxin. From 1 to 10 cc. of the resulting convalescent human serum was injected intravenously into diphtheria patients from one hour to eight days after routine administration of antidiphtheritic horse serum. The German investigators report that if the intravenous convalescent serum injection is made within the first twenty-four hours allergic symptoms are not noted. If the injection is delayed till the third or fourth day, however, an "inverse anaphylactic reaction" is produced, a generalized erythema, which usually disappears within a few hours. Delayed until the eighth day, i. e. until the end of the usual incubation period of spontaneous serum sickness, the "inverse anaphylactic reaction" is of "shocklike intensity." Following the induced erythema, the patients are completely desensitized to horse proteins. Spontaneous serum sickness does not develop in these desensitized children after completion of the usual incubation period. These results suggest that intravenous injection of convalescent human serum can be safely made on the third day following administration of diphtheria antitoxin and, thus given, may serve as a successful method of preventing serum sickness. The nature of the presumptive "secondary antibody" in the convalescent human serum, however, has not yet been determined. Fatalities have not thus far been reported from German hospitals as a result of this clinical research.

SYPHILIS IN NORTH CAROLINA

According to a recent press release from the North Carolina State Board of Health, 4,000 new cases of syphilis are being reported from that state each month as compared with 6,000 annually before the control campaign was launched. It is concluded therefore that the estimate of 300,000 cases of syphilis in the state made by the survey method was probably not exaggerated. Since the population of North Carolina is approximately 3,500,000, about 9 per cent of all the people in the state on the basis of this statement are syphilitic. Apparently also according to this release 48,000 new cases of syphilis develop each year and are actually reported. Irrefutable evidence of this startling conclusion should be offered before it is made the platform on which to plead for additional federal funds.

DANGERS OF PREGNANCY AFTER LONG INTERVAL

The impression that women who have long intervals between pregnancies are especially prone to obstetric difficulties and complications induced Ballard[1] to study 100 unselected pregnant women who had not had a pregnancy for ten or more years. Ninety per cent of the cases were from the clinic group, and the other 10 per cent from the private practices of the clinic staff. There were fifty-six white and forty-four colored patients, approximately the reverse ratio of the white and colored patients on the service. Eighty-five were between 26 and 40 years of age and forty were between 31 and 35. The average interval between pregnancies was 12.38 years and in 80 per cent the elapsed period between the present and previous pregnancies was between ten and fourteen years. Two patients, however, reported intervals of twenty-one years. Altogether, these women had experienced 207 previous pregnancies, fifty had one prior pregnancy each and one woman had had nine previous pregnancies. Eighty-seven patients delivered full-term living children and there were twelve deliveries of premature children, including one set of twins. There was one therapeutic abortion for hyperemesis gravidarum, and one premature stillbirth attributed to prolapse of the uterus and acute gonorrheal infection. The average duration of labor of ninety-three patients who were allowed to go into labor was slightly over twelve hours. Sixty-two patients had labor of ten hours or less, while twelve had twenty-four hours or more of labor. There were sixty-eight normal spontaneous deliveries, six cesarean sections and seventeen forceps deliveries. The uncorrected fetal mortality was 7 per cent, and one mother died of embolism. It was also concluded that white women are more apt to have long intervals between pregnancies than colored women;

1. Ballard, Margaret B.: A Study of 100 Pregnancies Occurring Ten or More Years After the Last Previous Pregnancy, Bull. School of Medicine University of Maryland 23: 63 (Oct.) 1938.

there is no difference between the longer and shorter intervals as to labor complications; the number of full term living children is slightly increased; the average duration of labor is increased about one fourth; operative deliveries are increased more than three times; the ratio of male to female babies is increased over the average, and the complications of toxemia, cardiovascular disease, placenta praevia, abruptio placentae, prolonged labor, uterine inertia, cervical dystocia and secondary anemia are definitely increased. She concludes, therefore, that the woman who has not had a pregnancy for ten years or more should receive the best antepartum care and should be delivered in a hospital and under expert obstetric supervision.

ALLERGIC CAPILLARY IMPERMEABILITY

The recent demonstration that in certain allergic conditions endothelial permeability is so reduced as to prevent the mechanical removal of colloidal irritants from local tissues introduces unsuspected complexity in theories of allergy. Direct microscopic study of capillary permeability was made possible by the synthesis of numerous relatively nontoxic colloidal dyes of known molecular size. If these dyes are injected intravenously into laboratory animals the rate of diffusion through the capillary endothelium is readily followed microscopically through a transparent window inserted in the skin or macroscopically by placing a drop of liquid petrolatum on the skin so as to make it semitransparent. Joyner and Sabin [1] of the Rockefeller Institute applied the latter technic to a study of the rate of outward diffusion of dyes or dye removal by capillary absorption after endermic injection. They found that if 0.025 cc. of a 2.5 per cent solution of pontamine sky blue, for example, is injected intracutaneously into a normal guinea pig the injected dye rapidly spreads outward through the regional lymphatics and interstitial tissue spaces. Rapid absorption by the local capillaries evidently takes place, since the color is soon demonstrable on all mucous surfaces. If the same volume of dye solution is injected endermically into a guinea pig during the allergic stage of experimental tuberculosis, however, this rapid outward diffusion and capillary absorption do not take place. The blue remains sharply localized for several hours and the mucous surfaces are not colored. The rate of local lymph formation is apparently markedly reduced. A similar though less pronounced reduction in endothelial permeability was demonstrated in guinea pigs during the allergic stage of streptococcic infection. During the late nonallergic or moribund stage of experimental tuberculosis the injected dye spreads outward more rapidly than in normal controls. There would seem therefore to be a terminal breakdown in the acquired allergic capillary impermeability. That injected antigens are localized at the site of injection in allergic animals was first emphasized by Opie,[2] who interpreted this localization as due solely to specific antibody reactions. The nonspecific mechanical factor demonstrated by the Rockefeller Institute physiologists, therefore, may lead to a reinterpretation of this conclusion. The strict localization of nonspecific irritants at the site of injection may conceivably lead to misleading local diagnostic inflammatory reactions.

RIBOFLAVIN DEFICIENCY IN MAN

Sebrell and Butler,[1] by means of a daily ration similar to that used by Goldberger and Tanner, succeeded in producing a cheilosis in ten of eighteen women in from ninety-four to 130 days after the beginning of the experiment. The diet consisted of cornmeal, cowpeas, lard, casein, flour, white bread, calcium carbonate, tomato juice, cod liver oil, syrup, and syrup of iodide of iron. On the eighty-sixth day of the experiment all were started on a weekly supplement of 30 mg. of crystalline ascorbic acid and 3.3 mg. of crystalline thiamin chloride. The lesions began as a pallor of the mucosa of the lip in the angles of the mouth without involvement of the buccal mucosa. Maceration and superficial transverse fissures appeared within a few days. These lesions resembled those described as perlèche. Four of the ten women with cheilosis were treated with daily doses of 1 or 2 mg. of synthetic crystalline riboflavin for from three to ten days, after which the dose was changed to 0.025 mg. per kilogram of body weight. All lesions completely disappeared after five, six, twenty and forty-seven days of treatment respectively. Another four women with cheilosis were treated for five days with 100 mg. of nicotinic acid daily. At the end of five days the lesions in all four were definitely worse and treatment with riboflavin was started. The lesions completely disappeared in three of the women after twelve, thirteen and twenty-four days of treatment but were so much more serious in the fourth that after forty-nine days the daily dose of riboflavin was increased to 0.05 mg. per kilogram of body weight. Thereafter the symptoms receded rapidly. One woman was treated with 100 mg. of nicotinic acid for forty-three days, at the end of which time, the lesions still being present, riboflavin was added to the diet followed by complete healing within ten days. The remaining woman developed the typical skin lesions of pellagra beginning thirty-six days after the experiment began and they were allowed to progress for forty days longer. After thirty days on 30 mg. of nicotinic acid daily these lesions were completely healed, although the cheilosis remained twenty-one days after the skin lesions of pellagra had completely healed and was not controlled until after riboflavin had been administered. These interesting observations, while preliminary in nature, indicate that a specific clinical syndrome can be experimentally produced and that the early developing cheilosis can be alleviated by the administration of small doses of crystalline synthetic riboflavin but not by nicotinic acid. The authors therefore believe that the condition may be considered a manifestation of riboflavin deficiency and suggest that the term ariboflavinosis be added to the nomenclature of vitamin deficiency diseases as a designation for the clinical condition due to deficiency of this vitamin.

ORGANIZATION SECTION

GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

PENNSYLVANIA

The Medical Society of the State of Pennsylvania is committed to its responsibilities to keep its members who live away from medical centers abreast of the progress of medicine. In 1933, when Dr. Donald Guthrie was president of the state society, postgraduate seminars were planned by the society and conducted by instructors of the medical schools in Pennsylvania. County medical societies desiring to organize classes of not less than twenty-five physicians communicated with the chairman of the committee on postgraduate education. In 1934 this committee consisted of six members with the former president of the state society as chairman, and he continues to act in this capacity.

Physicians who registered for the seminars indicated their preference of subjects for discussion. A series of six seminars given one day each week for six consecutive weeks was the usual plan. A registration fee of $10 was charged, which included the cost of a luncheon or dinner. Each instructor was allowed an honorarium of $25 as well as railroad fare. The state medical society agreed to absorb unavoidable deficits. Each county society which elected the plan was responsible for local organization, registration and other arrangements.

During 1934 six postgraduate seminars were held in medicine, gynecology and obstetrics, and roentgenology. In addition a course in physical therapy was presented over five successive days. Total registration for these seminars was 592. Six counties participated during the first year.

After this preliminary experience a definite procedure was established for securing the interest of county medical societies throughout the state. It was recommended that a seminar committee be appointed in each county society and also a subcommittee responsible for assigning subjects to teachers, for financial arrangements and for other local particulars. The state society committee listed the names of several hundred faculty members of the medical schools in Pennsylvania who were available for extension teaching. From this list county societies selected appropriate subjects and instructors. It was recommended that each seminar consist of three parts: a clinical ward class, didactic instruction and round table discussion. When more than twenty-five physicians subscribed for a course, it was possible to extend the series for more than six seminars. Hospitals were used as meeting places whenever possible. Graduate programs were not designed to take the place of regular county medical society meetings.

In 1935 approximately 640 practicing physicians participated in various seminars held throughout the state. In every section the program proved to be successful and no expense was incurred for the state medical society.

In 1936 the Pennsylvania State Department of Health offered, in cooperation with the state medical society, postgraduate institutes in obstetrics and pediatrics for practicing physicians. The state medical society's commission on maternal welfare and committee on pediatric education cooperated with the health department in making arrangements. Institutes in obstetrics and pediatrics were organized in forty-five towns throughout the state. These were financed with federal funds, and honorariums of $50 were paid instructors from the medical schools of Pennsylvania, in addition to travel expenses. The choice of subjects and speakers and many of the details connected with this program were arranged by the health department, which notified physicians that full day sessions would be held with three speakers on obstetrics or three on pediatrics. Lectures were mimeographed in pamphlet form and distributed to physicians who had enrolled. Three institutes were given in pediatrics and three in obstetrics. No registration fees were charged.

In 1937 the educational program in obstetrics and pediatrics was continued in several sections of the state. The general plan and arrangements for instruction were as noted for 1936 with the exception that only county medical societies which requested the programs were included, and six lectures were given on one day on both subjects. Approximately 300 practicing physicians received some graduate training in pediatrics and obstetrics during the year.

The chairman of the state society's commission on maternal welfare, Dr. James S. Taylor, has attempted during the past year to determine the number of hospitals in the state in which 500 or more obstetric patients are delivered annually. In hospitals with adequate clinical teaching material, conferences of members of the staff with other practicing physicians review maternal mortality statistics and other related data. These conferences are open to all physicians in the community and are designed for the purpose of determining the cause of each maternal and infant death. There are now eight centers throughout the state where such conferences are held. Obstetric conferences were begun in Philadelphia approximately three years ago, where meetings have been held once each month.

In December 1937 Dr. Thomas H. A. Stites was engaged as field secretary for the committee on graduate education of the state medical society. He visits officers of each county medical society in order to stimulate the interest of practicing physicians in graduate medical education, attends regular meetings of each county medical society and discusses the state society's program with members of local committees concerned with medical education. Whenever a county medical society does not have a sufficient number of members to warrant engaging instructors to give a series of lectures and clinics, it is urged to join with another county society in a cooperative program. When a county has shown sufficient interest in graduate education to organize a course, all further details concerning it are left entirely to local physicians.

Since the work of the field organizer began, courses have been given in twenty counties of the state outside of Allegheny, Dauphin and Philadelphia counties. Approximately 857 practicing physicians have participated and about 300 more in seven other sections of the state are planning to attend graduate seminars this year. Subjects that have been demanded most frequently are cardiology, obstetrics, pediatrics, cardiovascular-renal disease, neurology, gastro-enterology, internal medicine, syphilis, allergy, dermatology and diabetes. The graduate program has been largely self supporting and there have been few deficits for the state medical society.

The Medical Society of the State of Pennsylvania supports a library with a librarian in attendance in the building of the society at Harrisburg. An exchange has been set up with other state medical societies, so that journals and proceedings may be obtained as well as reprints for distribution to physicians practicing throughout the state. Approximately 60,000 reprints are available. For the year that ended in August 1938 there was a total of 319 loan packages distributed to physicians.

The Philadelphia County Medical Society organized its first postgraduate institute in 1936. Since then one has been held annually in a local hotel during March or April. Dr. Rufus S. Reeves is chairman of the committee on postgraduate institute. Every year one or two subjects are chosen for complete

discussion by instructors of the medical schools of Philadelphia and invited speakers. As many as seventy speakers sometimes participate in one institute. Cardiovascular-renal disease, diseases of the chest and respiratory tract and diseases of the digestive tract have been considered. The next annual program will be devoted to the blood dyscrasias and metabolic diseases. Scientific and technical exhibits are a part of the institute.

The institute was attended in 1936 by 564 individuals from thirteen states, in 1937 by 715 from seventeen states and two foreign countries, and in 1938 by 1,787 from thirty-six states and eleven foreign countries. A registration fee is charged, excepting for members of the Philadelphia county society; 802 of the 2,360 members of the society registered in 1938. There were 107 other Pennsylvania physicians who attended.

A library is maintained by the Philadelphia County Medical Society in its building. This library, which now contains 3,549 volumes and seventy-seven periodicals, has a librarian in attendance and is available not only to physicians practicing in Philadelphia but also to graduate students, medical students and nurses as well. During 1937 and 1938 there were 2,545 visitors.

In 1926 the Allegheny County Medical Society started a series of graduate courses of the extension type, patterned after those of the Kings County Medical Society of Brooklyn. A committee on graduate education consisting of five members was appointed to arrange and supervise graduate courses, to determine the fee for each course, to prepare and distribute announcements with the aid of the society's executive secretary and to make these activities self supporting. Allegheny's program for graduate medical education has been described by Dr. W. H. Robinson in the *American Medical Association Bulletin* (**29**:20 [Feb.] 1934).

Intensive courses were conducted also in which clinical material available in Pittsburgh was used, so that practicing physicians in the vicinity might have the opportunity to learn by actual experience and demonstration. Subjects which have been presented include neurology, pediatrics, roentgenology, ophthalmology, obstetrics, urology, pharmacology, physical therapy, gynecology and various aspects of internal medicine. From 1926 to 1934 six series of from six to eight courses each were given in local hospitals with a total registration of 314.

The Committee on Graduate Education of the Allegheny County Medical Society now consists of six members, two from the University of Pittsburgh School of Medicine and four from the county medical society, as well as two ex officio members. Since 1934 fifty or more practicing physicians have registered each year for graduate training. In 1938 sixty registered for the course of instruction in pneumonia. Courses which have proved most popular are pediatrics, ophthalmology, proctology, gynecology, obstetrics, physical therapeutics and gastro-enterology. Whenever possible, bedside teaching is emphasized and practicing physicians are given the opportunity to examine patients. Instructors are selected from the membership of the county society. Approximately 2,500 announcements are mailed to physicians in western Pennsylvania.

A cooperative postgraduate course in industrial hygiene was given at the University of Pittsburgh School of Medicine in October 1938 under the auspices of the county society and the medical school's department of industrial hygiene. Dr. T. Lyle Hazlett, director of the course, was assisted by five lecturers and other guest speakers. Subjects included traumatic surgery, toxicology of solvents, physiologic effects of industrial gases and metals, dermatoses and occupational health hazards. Three industrial plants in the vicinity of Pittsburgh were studied. There were thirty-three physicians registered, representing nineteen industries. A fee of $50 was charged. A mimeographed copy of the lectures was provided for each registrant.

During 1939 courses will be offered by the Allegheny county society in neurosurgery, clinical electrocardiography, proctology, gynecology, diseases of the ear, nose and throat, endocrinology and genito-urinary disease. Registration is limited in some courses. The registration fee for each is $10. Illustrated lectures, clinical demonstrations and, in some, laboratory instruction are included.

The Harrisburg Academy of Medicine has held a postgraduate medical assembly in Harrisburg each May for the past five years. The membership of the academy is approximately 160, and the attendance at each annual meeting varies from 150 to 500. Usually six guest speakers conduct the one day program. They are provided with travel expenses. A registration fee of $1 is charged each physician, and a copy of the proceedings of the medical assembly is given each registrant. Subjects of current interest are selected. In twelve sections of the state outside of the metropolitan areas similar one day graduate programs are provided.

The University of Pennsylvania Graduate School of Medicine, in addition to long courses in basic clinical studies, offers short personal courses in several subjects. These include cardiology, parasitology and tropical medicine, allergy and diabetes mellitus for practicing physicians, and neuropathology, clinical psychiatry, clinical biologic neurology and psychiatry, slit lamp microscopy and ophthalmic pathology for special students. Each course has limited registration and a fee. The course in clinical biologic neurology and psychiatry is designed for the members of the medical staffs of mental hospitals in Pennsylvania. It was given during October, November and December 1938. Registration was limited to ten.

During July 1938 the Pennsylvania Hospital of Philadelphia conducted a graduate course which included clinics, ward rounds, lectures, demonstrations and discussions on the various services of the hospital. A registration fee of $150 was charged, which allowed members of the staff who gave instruction honorariums of $5 or $10.

During 1938 one week of intensive courses in syphilis was given in Philadelphia for practicing physicians, in cooperation with the Pennsylvania State Department of Health. Facilities of the Hospital of the University of Pennsylvania and of the Pennsylvania Hospital were used. Discussions of the pathogenesis and laboratory and clinical aspects of syphilis, technic and interpretation of treatment, and methods of controlling the disease were included.

The Mercy Hospital, Philadelphia, has given a five day series of lectures each April since 1933. The series is designed for Negro physicians, dentists, medical students and graduate nurses. In April 1938 such subjects as pediatrics, neurology, obstetrics, otology, odontology, syphilis, otolaryngology and a symposium on diabetes were included. Members of the Philadelphia County Medical Society assist in the program each year. At the last session there were approximately sixty registrants.

The Pennsylvania Tuberculosis Society is cooperating with the Medical Society of the State of Pennsylvania in an effort to develop an organized program for continuing the education of the profession and of the public in tuberculosis. Tuberculosis committees are being organized in county medical societies throughout the state. A physician is provided by the tuberculosis association to visit county medical societies to discuss laboratory tests and the clinical aspects of the disease. A motion picture sound film on "Diagnostic Procedures in Tuberculosis" has been utilized by medical societies in several sections of the state. Scholarships are offered to physicians for graduate study in tuberculosis.

Of the 13,205 physicians in the state, 9,040 are members of the Medical Society of the State of Pennsylvania. The society is notably generous in its policy of providing, without cost to its component societies, speakers representing its various disease control committees, such as cancer, pneumonia, diabetes, appendicitis, syphilis and maternal mortality.

STATE MEDICINE IN WASHINGTON

The Bellingham Eagles Lodge in the state of Washington has announced its intention to undertake a campaign for a state medicine act involving the "passage of a law providing medical treatment for citizens of the state at state expense." The Bulletin of the King County Medical Society for June 6, 1938, expresses the opinion that:

> While it is doubtful if the type of medical service which has so long been sponsored by the Eagles' organization will ever be in very wide demand, nevertheless, this movement on the part of this one organized group should be watched carefully.

THE IMPORTANCE OF POSTGRADUATE MEDICAL EDUCATION

Abridgment of an address read by George Morris Piersol, M.D., Philadelphia, at the ninetieth anniversary of the Philadelphia County Medical Society, Jan. 27, 1939.

It is eminently fitting that we should direct our attention to the question of postgraduate medical education on this, the ninetieth, anniversary of the Philadelphia County Medical Society. Long aware of the importance of postgraduate study, our society has been a pioneer in this field of activity, which at present is engaging the interest of medical educators and medical societies throughout this country. The practical problem which is an outstanding challenge to the medical profession and medical education today is how to devise effective methods which will afford practicing physicians the opportunities for adequate postgraduate study and, having provided such facilities, to induce physicians to utilize them. In this way and in this way alone can we hope to make available to the people of this country the ever increasing benefits of modern medical knowledge.

Without legislative coercion or even the advice of economists, the various medical groups, on their own initiative, have set up properly constituted boards for the certification of specialists. This movement had its inception in such highly specialized groups as the ophthalmologists, the otolaryngologists and the neuropsychiatrists and within the last few years has been extended so as to embrace all clinical subdivisions of medicine, including now the internists and the general surgeons. The requirements laid down by these certifying boards are so exacting that those who seek special certification must present satisfactory evidence of adequate training in the medical sciences as well as in their particular field.

Weekly Roster and Medical Digest 34: 781-783 (Feb. 11) 1939.

In the past there has been a tendency to regard postgraduate medical education as something detached and apart from the broad question of medical training. From an educational point of view the different phases in the training of a physician should be looked on as a coordinated whole. Every step in the sequence of a medical education, premedical studies, the medical school, the years in a hospital as an intern and later as a resident or fellow, on through the period of general practice and postgraduate training, leading in some instances to specialism, should have as its objective one underlying and dominant aim, namely the proper and continued training of physicians well qualified to cope successfully with the health needs of the country. The more widespread such a concept of medical education becomes and the more uniformly such a program is adopted, the greater will be the improvement in the quality of medical service furnished by us. When, as the result of further progress in all aspects of medical education, the medical care of the people of this country is placed on a more satisfactory and efficient basis, many of the criticisms that are sometimes leveled at the medical profession will be silenced.

It is important for a society such as ours, which rightfully undertakes to guide and influence medical thought, to be ever mindful that the basic factor underlying continued confidence in the medical profession is education sufficiently broad in scope to include graduate as well as undergraduate training. Therefore in developing an adequate educational program every consideration should be given to postgraduate medical education, opportunities for which should be made readily available to the practicing physician through the well organized efforts of medical schools, hospitals and medical societies.

OFFICIAL NOTES

ADDRESSES BY OFFICIAL STAFF

DR. MORRIS FISHBEIN:

April 1—*University of Illinois Students*, Y. M. C. A., Chicago.
April 2—Phi Delta Epsilon, Knickerbocker Hotel, Chicago.
April 3—Vanderbilt University School of Medicine, Nashville, Tenn.
April 4—Nashville Academy of Medicine, Nashville, Tenn.

April 18—Indiana Tuberculosis Association, *Indianapolis*.

RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title Your Health, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).

Changes in this time will be necessary to take into consideration daylight saving time. Announcement of this change will appear in advance in THE JOURNAL. Owing to network conflicts the Chicago broadcast will not occur at 1 p. m. on Wednesday but there will be a rebroadcast from a recording over Station WENR at 8 o'clock each Monday evening. The program broadcast each Monday will be identical with the network program of the preceding Wednesday.

It has been necessary to curtail the length of the series by omitting the last two programs, which would have been broadcast June 14 and June 21. The series, therefore, will end with the broadcast scheduled for June 7.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

April 5. Don't Believe Everything!
April 12. Learning to Live.
April 19. "Accidents Don't Just Happen—"

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status.—S. 795 has been reported to the Senate, without amendment, with a recommendation that it pass, proposing to authorize an appropriation of $11,580,000 annually to enable each state to establish, extend and improve services for educating children who are crippled, blind, partially seeing, deaf, hard of hearing, defective in speech, cardiopathic, tuberculous or otherwise physically handicapped, and who for their education require an expenditure of money in excess of the cost of educating physically normal children.

Bills Introduced.—S. 1843, introduced by Senator Bailey, North Carolina, contemplates the assignment of medical officers of the Public Health Service for duty on vessels of the Coast and Geodetic Survey and provides that all commissioned officers, ships' officers and members of the crews of the vessels of the United States Coast and Geodetic Survey, including those on shore duty and those on detached duty, whether on active duty or retired, and all dependent members of families of such personnel shall be entitled to medical, surgical and dental treatment and hospitalization by the Public Health Service in the same manner and to the same extent as are now or may hereafter be provided by law and regulations for officers and enlisted men of the United States Coast Guard and their dependents. S. 1899, introduced by Senator Harrison, Mississippi, provides that there shall be in the Public Health Service a commissioned medical officer to be known as the Assistant to the Surgeon General and who shall perform such duties as the Surgeon General may prescribe and shall act as Surgeon General during the absence or disability of the Surgeon General. The Assistant to the Surgeon General, while serving as assistant, shall have, it is proposed, a rank in the Public Health Service which shall correspond to that held by a brigadier general in the United States Army. H. R. 5026, introduced by Representative Reece, Tennessee, proposes that all acts conferring compensation and hospitalization benefits on veterans of the World War shall be extended to include veterans who served on the Mexican border as members of the Regular Army or National Guard from June 1916 to April 1917 and who received honorable discharges. H. R. 5038, introduced by Representative Terry, Arkansas, proposes, among other things, to authorize an annual federal appropriation of such amount as may be necessary to enable each state to furnish financial assistance to needy incapacitated individuals.

DISTRICT OF COLUMBIA

H. R. 5221, introduced by Representative Bolles, Wisconsin, provides that retired members of the police and fire departments of the District of Columbia shall receive necessary medical or surgical services, medicines and hospitalization for illnesses or disabilities reasonably calculated to be the outgrowth of injuries received or disease contracted in line of previous active duty. H. R. 5238, introduced by Representative Nichols, Oklahoma, proposes to regulate the practice of optometry in the District of Columbia. The practice of optometry is defined to be the "application of optical principles through the use of mechanical methods and devices in the examination of the human eye for the purpose of ascertaining visual defects, and the determination of proper lenses for the aid and relief thereof."

STATE MEDICAL LEGISLATION

Illinois

Bills Introduced.—S. 241 proposes to limit licensure in the healing arts to citizens of the United States. H. 498 proposes that whenever in a civil or criminal proceeding issues arise on which the court deems expert evidence desirable, the court may, on the request of either party to the proceeding, appoint one or more experts, not exceeding three on an issue, to testify at the trial. Either party to the proceeding, however, may call expert witnesses provided reasonable notice is given the adverse party of the name and address of the experts to be called.

Michigan

Bills Passed.—The following bills passed the house March 23: H. 145, proposing to authorize the organization of corporations to operate nonprofit hospital service plans whereby hospital service may be provided by any hospital or group of hospitals with which such corporations have contracts to such of the public as become subscribers to the plans entitling each subscriber to stated hospital care; and H. 215, proposing to authorize the organization of corporations to establish, maintain and operate nonprofit medical care plans, whereby medical care is provided at the expense of the corporation to such persons or groups of persons of low income as become subscribers to such plans under contract which entitle each such subscriber to definite medical and surgical care, appliances and supplies, by licensed physicians in their offices, in hospitals and in the home.

Minnesota

Bill Passed.—H. 853 passed the house March 22, proposing to prohibit, except on the written prescription of a licensed physician, dentist or veterinarian, the retail sale or distribution of barbital, veronal, propanol, ipral, dial, neonal, sandoptal, amytal, phenobarbital, phanodorn, noctal, allonal, medinal or any preparation, mixture or other substance containing any of the aforementioned substances.

Missouri

Bills Introduced.—H. 658, to amend the osteopathic practice act, proposes that "The system, method or science of treating diseases of the human body, commonly known as osteopathy, and as taught and practiced in *any school of osteopathy recognized and approved by the American Osteopathic Association,* is hereby declared not to be the practice of medicine and surgery" within the meaning of the medical practice act and not subject to its provisions. The present law has, in place of the words italicized "the American School of Osteopathy of Kirksville, Missouri." H. 662, to amend the food and drug act, proposes to repeal that section of the act prohibiting the manufacture, production, sale or possession of any article of food or drug which is adulterated or misbranded and to substitute for it a provision requiring all drugs, except those described in original, nonrefillable, hand-written prescription, signed by a licensed physician or veterinarian, to be labeled with the true English name, together with a statement as to the danger and sometimes untoward effects of the drug in question and to give the names of at least two active antidotes printed on the label in a type as large as any used thereon.

New Jersey

Bills Introduced.—S. 210, to amend the law granting a lien to a licensed physician treating a person injured through the negligence of another, proposes to deprive the attending physician of the lien if, without the consent of his patient, he makes any report whatever concerning the nature of the injuries to the person whose negligence is alleged to be responsible for the injury or to that person's insurance carrier. S. 214 proposes to require any county prosecutor who receives information as to the existence of any marihuana weed in his county to notify the State Department of Health of the fact and to require the department on receipt of such information to investigate concerning the existence of the weed in that location. The department is then to certify to the county prosecutor as to the existence of the weed and the prosecutor is then empowered to destroy the weed if it is present. A. 464 proposes that at least one member of the State Board of Health shall be a registered pharmacist. A. 493 proposes to permit any person more than 21 years of age, of good moral character, a citizen of the United States, who has received a license to practice chiropractic in this state and who has completed a course of study of not over [sic] one thousand hours of physiotherapy, including dietetics, in a medical or professional school or a special course designated and approved by the state board of medical examiners, to be admitted to an examination in physiotherapy and dietetics to be given by the board for a license to practice physiotherapy and dietetics.

New York

Bills Passed.—The following bills passed the assembly March 22: A. 1428, proposing that a license to practice osteopathy shall entitle the holder thereof to use instruments for minor surgical procedures and to use anesthetics, antiseptics, narcotics and biological products; and A. 1433, proposing to

prohibit except on the written prescription of a licensed physician, dentist or veterinarian, the retail sale or distribution of barbital, sulphonethylmethane (trional), diethylsulphor diethylmethane [sic] (tetronal), carbromal, chloral or chloral hydrate, or chlorbutanol.

Bills Introduced.—S. 1492 proposes to limit licensure in medicine to citizens of the United States. The present law limits licensure to citizens of the United States or persons who have declared their intention of becoming such citizens. S. 1510 proposes to prohibit the manufacture, distribution or advertising of adulterated and misbranded foods. S. 1545 and A. 2042 propose to declare the policy of the state that the manufacture and sale of adulterated or misrepresented foods, drugs and cosmetics are matters of state concern and to create a temporary state commission to recommend to the legislature a comprehensive program for the regulation and prevention of the manufacture and sale of adulterated or misrepresented foods, drugs and cosmetics and to submit proposals designed to prevent and eliminate false and misleading advertising relating to the products named. A. 2028 proposes to repeal the law granting liens to hospitals treating persons injured through the negligence of others.

North Carolina

Bill Introduced.—S. 336 proposes to enact a separate naturopathic practice act and to create a board of naturopathic examiners to examine and license persons applying for licenses to practice naturopathy. The bill states that naturopathy is "defined to mean the use and practice of natural methods as taught in standard colleges of Naturopathy and as defined and enacted by Congress February 16, 1931 [as a matter of fact no such law was ever enacted by Congress], embracing the physiological, mechanical and material health sciences to aid in purifying, cleansing and normalizing the human organism, for the preservation or restoration of health, according to the fundamental principles of anatomy, naturopathic physiology and applied psychology, as may be required." The bill specifically proposes to permit such licentiates to practice "nonsurgical gynecology" and "midwifery" but prohibits its licentiates from practicing "materia medica, radium therapy, medicine or surgery." Aside from the practices prohibited specifically, licentiates apparently will be able to practice without restriction.

Oklahoma

Bill Introduced.—H. 496, to amend the medical practice act, proposes to require all licensed physicians to register annually with the board of medical examiners on or before July 1 and to pay at that time an annual registration fee of $3.

Pennsylvania

Bill Introduced.—H. 565 proposes to enact a separate practice act for persons practicing the natural healing arts and to create a board of examiners to examine and license applicants for such licenses. The board, apparently, is to be authorized to issue two sorts of licenses: (1) a license permitting the treatment of the body by any movements, adjustments and manipulations performed by the hands or nonsurgical instruments or appliances and (2) a license conferring the rights just stated and, in addition, permitting the use of any physical forces, such as air, light, water, heat, cold, electricity or any of their derivatives, phytotherapy, dietetics and exercises, or any other system or systems of therapeutics correlated with the foregoing therapeutic measures.

Rhode Island

Bills Introduced.—S. 198 proposes to enact a separate naturopathic practice act and to create a board of examiners in naturopathy to examine and license applicants for licenses to practice naturopathy. The bill states that "the practice of the profession of naturopathy is hereby designated as non-medical and drugless, and is defined as a science dealing with the diagnosis and treatment of disease through natural therapeutics. It shall embrace and include physiological, mechanical and dietetic sciences, such as mechano-therapy, electro-therapy, use of diet and herbs including powdered and dehydrated foods and fruits, and other methods as taught in the various recognized schools of naturopathy, excepting, however, surgery and the prescription of compounded drugs." H. 884, to amend the osteopathic practice act, proposes that "The acceptance of any federal law or regulation or the application thereof by any department or bureau of this state which affects medical practice or the control of public health or medical care of state dependents, shall apply equally to practitioners of osteopathy and practitioners of medicine." H. 913 proposes to prohibit the sale or distribution of appliances, condoms, drugs or medicinal preparations intended or having special utility for the prevention of venereal diseases and/or used in gynecologic hygiene or treatments except by places duly registered by the division of narcotics and pharmacy or by licensed physicians.

Wisconsin

Bills Introduced.—S. 288 and A. 519 introduced at the request of the Wisconsin Hospital Association, Conference of Catholic Hospitals and the Wisconsin Medical Society, propose to authorize the formation of corporations to establish and operate nonprofit hospital service plans whereby certain hospital service may be provided by participating hospitals to persons who may become subscribers to such plans. The term "participating hospital" refers to any hospital which has a contract with a nonprofit hospital service membership corporation to render hospital service to subscribers to the hospital service plan. The bill proposes that members of such corporation shall be (1) three nonmedical persons designated by each participating hospital, at least two of whom shall be directors or be active in the operation of such participating hospital; and (2) a number of persons equal to the number of participating hospitals.

WOMAN'S AUXILIARY

Arizona

Dr. J. D. Hamer spoke, at a recent meeting of the auxiliary to the Maricopa County Medical Society held in Phoenix, on the special autumn meeting of the House of Delegates of the American Medical Association.

Michigan

The board of directors of the auxiliary to the Michigan State Medical Society met in Detroit November 18. Mrs. P. R. Urmston, president, gave a report on the meeting of the board of directors of the auxiliary to the American Medical Association, which was held in Chicago November 11. Proceeds from a rummage sale held by the auxiliary to the Bay County Medical Society amounted to $75. William J. Burns, executive secretary, Michigan State Medical Society, spoke before the auxiliary in November on the national health program.

The auxiliary to the Calhoun County Medical Society has donated seven wheel chairs to the new Community Hospital.

The auxiliary to the Jackson County Medical Society was addressed by Dr. Philip A. Riley on the pending legislative measures that were approved at the recent state medical meeting in Detroit. Dr. Riley discussed the measures based on socialized medicine, stating that Jackson, Calhoun and Washtenaw counties have far more hospital beds than are needed at present.

Oregon

The auxiliary to the Multnomah County Medical Society presented its first hobby show last September. There were seventy-four exhibits. In October the auxiliary was addressed by Dr. Charles E. Sears, Portland, on "What the Medical Association Can Do to Provide Better Medical Aid to the People," and Dr. Robert L. Benson, Portland, on "The National Health Conference."

Virginia

The auxiliary to the Mid-Tidewater Medical Association met in January at West Point. Dr. Wright Clarkson of Petersburg spoke on cancer work. Mrs. Joseph Bear, Richmond, also spoke on the work of the woman's field army of the American Society for the Control of Cancer.

The auxiliary to the Norfolk County Medical Society met January 11. Mrs. Hawes Campbell, president of the auxiliary to the Medical Society of Virginia, spoke on health problems.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

State Medical Meeting in Phoenix.—The Arizona State Medical Association will hold its forty-eighth annual meeting in Phoenix April 13-15 with headquarters at the Hotel Westward Ho. Dr. Harold W. Rice, Bisbee, is president. The guest speakers will include:

Dr. John C. Jones, Los Angeles, Extrapleural Pneumothorax in the Treatment of Phthisis.
Dr. Frank T. Hogeland, Sonora, Mex., The Medical Control of Silicosis.
Dr. Edward William Alton Ochsner, New Orleans, Thrombophlebitis.
Dr. Norman F. Miller, Ann Arbor, Mich., Common Lesions of the Cervix and Their Treatment.
Dr. Webb W. Weeks, New York, Eye Diseases in Their Relation to General Medicine.
Dr. Lewis F. Morrison, San Francisco, Impaired Nasal Ventilation in the Adult.
Dr. Edward H. Cary, Dallas, Texas, Federal Trends in Medical Care and Health Legislation.
Dr. Frederick Kellogg, Long Beach, Calif., Recent Advances in Syncope or Medical Shock.

The speakers from Arizona will include:

Dr. Dermont W. Melick, Williams, Artificial Pneumothorax: 1. Its Application to the Ambulatory Patient.
Dr. Leslie B. Smith, Phoenix, Diabetes Mellitus and Observations with Protamine Zinc Insulin.
Dr. Lyle A. Condell, Safford, Undulant Fever and Its Treatment with Sulfanilamide.
Dr. Robert E. Hastings, Tucson, Low Back Pain with Sciatic Radiation.
Dr. John W. Pennington, Phoenix, Enuresis.
Dr. Howard C. James, Tucson, Metabolism in Pregnancy.
Dr. Zenas B. Noon, Nogales, Differentiation of Parietal and Intra-Abdominal Pain.
Dr. Joseph Bank, Phoenix, Diagnostic Value of and Indications for Gastroscopy.

The woman's auxiliary will meet at the Westward Ho Thursday, April 13-14. Speakers will include Drs. Jack B. Eason, Phoenix, director, maternal and child health, state department of public health, on "Role of the Auxiliary in Maternal and Child Health Program," and Dr. Miller.

CALIFORNIA

Lectures for the Public.—The fifty-seventh course of popular medical lectures will be offered by Stanford University School of Medicine, San Francisco, in Lane Hall as follows:

Dr. Edwin L. Bruck, April 7, Pneumonia and Its Treatment by Recent Serums and Drugs.
Dr. Harold A. Fletcher, April 21, Electrical Engineers Come to the Aid of the Hard of Hearing.
Claude A. Shull, M.A., May 5, What Are the Movies Doing to the Emotional Stability of Our Children?
Dr. Paul A. Gliebe, May 19, Emotions and Physical Diseases.

CONNECTICUT

Hospital News.—A building program is under way for Mount Sinai Hospital, Hartford, to permit the renovation and construction of an east wing, thus increasing the bed capacity to more than 100. It is hoped to secure $250,000 in a campaign for funds which was to begin in February.

New Chief of Crippled Children Division.—Dr. Louis Spekter has been appointed chief of the division of crippled children of the Connecticut State Department of Health, Hartford, succeeding Dr. Russell V. Fuldner, resigned. Dr. Spekter graduated at the University of Rochester School of Medicine, Rochester, N. Y., in 1933.

Committee to Aid Yale's Program of Development.—A committee of physicians and laymen has been appointed to aid Yale University in the development of its program in medicine and public health, it was announced at a meeting of medical alumni in the Sterling Hall of Medicine, New Haven, February 23. Dr. Harvey Cushing, Sterling professor of neurology emeritus and director of studies in the history of medicine, will be general chairman. An executive committee is composed of the following: Dean Stanhope Bayne-Jones, chairman; Fuller F. Barnes, Bristol, Conn.; William McCormick Blair, Chicago; George Parmly Day, New Haven; Thomas W. Farnam, New Haven; Dr. Norman E. Freeman, Philadelphia; Harry C. Knight, New Haven; Dr. Fred T. Murphy, Detroit; Charles-E. A. Winslow, Dr.P.H., New Haven, and Dr. Milton C. Winternitz, New Haven. The committee is to assist in making better known among the alumni and friends of the university the work of Yale in medicine and public health. Large sums, contingent on the receipt of further gifts, have been pledged for the development of this work.

GEORGIA

Personal.—Dr. John L. Elliott, Savannah, has been elected coroner of Chatham County.——Dr. Young H. Yarbrough, Milledgeville, has been appointed assistant superintendent of the Milledgeville State Hospital.——Dr. James A. Thrash, Columbus, health officer of Columbus and Muscogee counties, has been elected superintendent of the Muscogee County Tuberculosis Hospital.——Dr. Clarence M. Sharp, formerly of Lake Kushaqua, N. Y., has been appointed superintendent of the state tuberculosis sanatorium at Alto.

ILLINOIS

Society News.—Dr. Leonard T. Furlow, St. Louis, discussed "Acute Head Injuries" before the Sangamon County Medical Society, Springfield, February 2.——Dr. Lee C. Gatewood, Chicago, addressed the Will-Grundy County Medical Society at Joliet March 24 on "Jaundice—Its Causation and Clinical Study."

Chicago

Dr. Lord Will Discuss Pneumonia.—Dr. Frederick T. Lord, clinical professor of medicine emeritus, Harvard Medical School, Boston, will lecture at a joint meeting of the Chicago Medical Society and the Institute of Medicine of Chicago April 5 on "The Serum Treatment of Pneumonia." A sound film "The New Day" will also be shown.

The Gehrmann Lectures.—Dr. Herbert C. Clark, director, Gorgas Memorial Institute of Tropical and Preventive Medicine, Inc., Panama, Canal Zone, will deliver the Gehrmann Lectures for 1938-1939 of the University of Illinois College of Medicine in the Medical and Dental College Laboratories Building, 1853 West Polk Street. His subjects are:

April 12, Malaria. Its Effect on Labor Efficiency in the Tropics.
April 13, Amebiasis, Clinical and Nonclinical.
April 14, Modern Factors Favoring Spread of Diseases.

Branch Meetings.—Dr. James B. Collip, professor and head of the department of biochemistry, McGill University Faculty of Medicine, Montreal, Canada, will discuss "Results of Recent Laboratory Studies on Anterior Pituitary Hormones" before the North Side Branch of the Chicago Medical Society April 6. A symposium on diseases of bones will be presented before the North Shore Branch April 4; Dr. Arthur Steindler, Iowa City, will discuss "Fracture Deformities and Contractures" and Dr. Charles F. Geschickter, Baltimore, "Malignant Tumors of Bones."

INDIANA

Emeritus Staff Members Honored.—A new division of emeritus members was recently created at Deaconess Hospital, Evansville, to honor older staff physicians. The following twelve physicians have been designated charter members: Walter H. Coleman, Earl Conover, George C. Dunlevy, William H. Field, Charles B. Harpole, Charles W. Hartloff, Bleeker J. Knapp, William E. McCool, Henry Nenneker, Marcus Ravdin, Olen C. Stephens and William P. Woods. The group was honored at a dinner February 21, the forty-seventh anniversary of the hospital.

Society for the History of Medicine.—The Indiana Association of the History of Medicine was organized at a meeting February 15 in the library of Eli Lilly & Co., Indianapolis. Dr. Edgar F. Kiser was chosen president. The next meeting will be held May 17 at the same place. It is planned to hold quarterly meetings, and application for membership has been made to the American Association of the History of Medicine. Additional information may be obtained from Mrs. Irene Strieby, library, Eli Lilly & Co. Dr. William N. Wishard Jr., Indianapolis, addressed the recent meeting on the life of Edward Jenner.

Personal.—Mr. Rollen Waterson, Whiting, has been appointed executive secretary of the Lake County Medical Society, a recently created position. Temporary headquarters have been set up in the Hammond City Hall. The society recently became incorporated.——Dr. Philip H. Becker, Crown Point, has been appointed superintendent of the Lake County Tuberculosis Sanatorium, succeeding the late Dr. James O.

Parramore; he formerly served as assistant. According to the state medical journal, a new wing providing 100 beds is about to be opened, and a new chapel is to be named in honor of Dr. Parramore.——Drs. Oliver V. Schuman and Nathan I. Kithcart, Columbia City, were recently voted honorary membership in the Whitley County Medical Society.

MARYLAND

New Physician-in-Chief of Baltimore City Hospitals.—Dr. John T. King, associate in medicine, Johns Hopkins University School of Medicine, Baltimore, was recently appointed physician-in-chief of the Baltimore city hospitals, filling the vacancy caused by the death of Dr. Thomas R. Boggs. Dr. King graduated at Johns Hopkins in 1914.

Graduate Week in Medical History.—"Medicine in the Renaissance" will be the theme of the second graduate course in medical history at the William H. Welch Medical Library, April 24-29, under the auspices of the Institute of the History of Medicine, Johns Hopkins University, Baltimore. The course will precede the annual meeting of the American Association of the History of Medicine in Atlantic City, N. J., April 30-May 1, so that members of the course can proceed directly from Baltimore to Atlantic City. A registration fee of $5 will be charged. The speakers will be:

Dr. Henry E. Sigerist, director of the institute, Economic, Social and Political Foundations of the Renaissance.
Ludwig Edelstein, Ph.D., Ancient Traditions in Medieval and Renaissance Thought.
J. Ben Robinson, D.D.S., dean, University of Maryland School of Dentistry, Influences Exercised by Conventional Medicine on the Beginning of Autonomous Dental Education.
Ruth Musser, M.S., and John C. Krantz Jr., Ph.D., department of pharmacology, University of Maryland School of Medicine, The Friendship of Christopher Wren and Robert Boyle.
Dr. Owsei Temkin, The Physician in the Renaissance.
Dr. Sanford V. Larkey, Hygiene and Public Health in the Renaissance.
Dr. John Rathbone Oliver, The Oxford of Anthony Wood.

The subjects of the seminars planned for each afternoon are "The Concept of the Renaissance," "Bibliographic Problems of Renaissance Literature," "Some Biological Problems of the Renaissance," "Diseases Prevailing in the Renaissance and Their Interpretation" and "Medical Literature in the Vernacular: English, German, French, Italian." Isaiah Bowman, LL.D., president, Johns Hopkins University, will open the course and Dr. Alan M. Chesney, dean of the school of medicine, will deliver the closing address. Applications to attend the course should be addressed to the Institute of the History of Medicine, 1900 East Monument Street, Baltimore, before April 10.

MICHIGAN

Undulant Fever at State College Traced.—Defective plumbing combined with the use of a faulty sterilizer in the bacteriology laboratory was the cause of an outbreak of undulant fever which caused the death of one student and the illness of forty-eight others at Michigan State College, East Lansing (THE JOURNAL, February 18, p. 653). According to the state department of health, back-siphonage of contaminated water from a sink in the basement of the undulant fever laboratory and its spread through the bacteriology building's distributing system to all outlets on the second and third floors has been demonstrated. Glassware used in growing undulant fever cultures was washed at this sink after being removed from a steam sterilizer. Tests indicated that living germs were present on the glassware after it had been in the sterilizer for one hour. This had been considered ample time to kill the germs if the apparatus had functioned properly, it was said. Immediate causes of the outbreak have been corrected.

Society News.—Dr. Jerome R. Head, Chicago, presented a "Survey of Thoracic Surgery" before the Muskegon County Medical Society February 17.——Dr. Robert L. Schaefer, Detroit, addressed the Calhoun County Medical Society, Battle Creek, February 7 on "Diagnosis and Treatment of Gonadal Immaturity."——Dr. Edward F. Sladek, Traverse City, addressed the Northern Michigan Medical Society in Petoskey February 9 on latest trends in state legislation concerning organized medicine.——Dr. Carl F. Schmidt, Philadelphia, discussed "New Drugs—How They Are Discovered and Introduced" before the Wayne County Medical Society and the Detroit Retail Druggists Association February 27.——The Detroit Dermatological Society was addressed February 21 by Drs. Arthur E. Schiller on "The Industrial Nurse"; William T. Krebs, "The Plant Physician"; John Ewart Caldwell, "The Interpretation of the Michigan Industrial Disease Law," and Mr. L. B. Case, "The Plant—Its Equipment and Chemistry."

MINNESOTA

Clarence M. Jackson Lecture.—The Clarence M. Jackson Lecture is under the auspices of the Phi Beta Pi Fraternity of the University of Minnesota and not the Hennepin County Medical Society as stated in THE JOURNAL March 11, page 1005.

Harold S. Boquist Lecture.—Dr. Henry C. Sweany, medical director of research, Chicago Tuberculosis Sanatorium, Chicago, will deliver the annual Harold S. Boquist Lecture at the University of Minnesota Medical School, Minneapolis, April 4, on "Study of the Pathogenesis of Tuberculosis by Correlating Age and Morphology of Primary Tubercles."

MISSOURI

State Medical Meeting at Excelsior Springs.—The Missouri State Medical Association will hold its annual session in Excelsior Springs April 10-12. The speakers will include:

Dr. Alexis F. Hartmann, St. Louis, Clinical Use of Sulfanilamide and Its Derivatives.
Dr. Jennings C. Litzenberg, Minneapolis, The Conduct of Normal Labor and Its Abuses.
Dr. William M. Ketcham, Kansas City, The Male Sex Hormone.
Drs. John J. Boucek, Charles E. Gerson and Andrew C. Henske, all of St. Louis, Pneumoperitoneum in the Treatment of Pulmonary Tuberculosis.
Dr. Warren H. Cole, Chicago, Surgical Aspects of Peptic Ulcer.
Dr. Goronwy O. Broun, St. Louis, Clinical Studies of Vitamin K.
Dr. James Archer O'Reilly, St. Louis, The Crippled Child in Missouri.
Dr. Idys Mims Gage, New Orleans, Acute Trauma of the Abdominal Viscera (Subcutaneous Injury of the Abdomen); Surgery of Acute Cholecystitis.
Dr. George Wilse Robinson Jr., Kansas City, Treatment of Depressions and Melancholias.
Dr. Sumner L. S. Koch, Chicago, The Worker's Hand.
Dr. Raymond O. Muether, St. Louis, Recent Developments in the Treatment of Lobar Pneumonia.
Dr. Fred M. Smith, Iowa City, Diagnosis and Treatment of Coronary Thrombosis.
Dr. Drew W. Luten, St. Louis, The Heart.
Dr. Jacob Kulowski, St. Joseph, The Modern Approach to the Problem of Acute Hematogenous Osteomyelitis.
Dr. Evarts A. Graham, St. Louis, Accomplishments of Modern Chest Surgery.
Dr. William Malamud, Iowa City, Modern Trends in the Treatment of Schizophrenia.
Dr. Byrl R. Kirklin, Rochester, Minn., The Value of X-Ray Diagnosis as It Pertains to the Physician in General Practice.
Dr. Alfred W. Adson, Rochester, Minn., The Status of Sympathectomy for Hypertension.
Dr. Walter M. Whitaker, Quincy, Ill., Pneumonia in Childhood.
Dr. Frederick J. Taussig, St. Louis, The Role of the Ellis Fischel State Cancer Hospital in the Control of Cancer in Missouri.
Dr. Paul F. Cole, Springfield, Missouri Cancer Survey, 1938.
Dr. Carl F. Vohs, St. Louis, Prepayment Medical and Hospital Care.

Drs. Bernard W. Hays, Jackson, and James R. McVay, Kansas City, will deliver addresses as president and president-elect respectively.

NEW YORK

Course on General Medicine.—Members of the Columbia County Medical Society attended a course on general medicine at the Hudson City Hospital in recent weeks. The lecturers, all of New York, were:

Dr. William Goldring, Physiological Interpretation of the Clinical Manifestations in Renal Diseases and Hypertension, January 10.
Dr. Samuel H. Geist, Practical Endocrinology, January 24.
Dr. Ralph G. Stillman, Significance of Laboratory Tests and Methods in the Practice of Medicine, February 7.
Dr. Alexander B. Gutman, Dehydration, Acidosis and Shock, February 21.
Dr. Edward M. Livingston, Abdominal Pain, March 7.

Society News.—Dr. Abraham H. Aaron, Buffalo, addressed the Medical Society of the County of Westchester March 21 on "Treatment of Selected Gastrointestinal Conditions from the Viewpoint of the General Practitioner."——Drs. Edward C. Reifenstein and Fred L. Ritter addressed the Onondaga County Medical Society, Syracuse, March 7 on "Recent Advances in Pneumonia Therapy" and "Diverticulitis with Perforation" respectively.——Dr. Perry G. Goldsmith, Toronto, Ont., addressed a joint meeting of the Syracuse Academy of Medicine and the Syracuse Ear, Nose and Throat Club March 21 on "Diseases of the Upper Respiratory Tract with Hoarseness as a Symptom."——Dr. John E. Deitrick, New York, addressed the Dutchess County Medical Society February 8 at the Hudson River State Hospital on "Failure of the Peripheral Circulation."

New York City

Personal.—Dr. George K. Meynen, Jamaica, was recently honored with a testimonial dinner given by about 200 friends and colleagues of Jamaica Hospital. Dr. Meynen has prac-

ticed medicine in Queens for fifty-two years; he was one of the founders of Jamaica Hospital and its first surgeon, according to a bulletin from the hospital.

Symposium on Venereal Disease.—Under the auspices of the department of urology of New York Medical College and Flower-Fifth Avenue and Metropolitan hospitals, the New York City Department of Health and the Social Hygiene Committee of the New York Tuberculosis and Health Association, a symposium on "the human side of the venereal diseases" was presented February 8 at the Meinhard Health Center and the East Harlem Health Center.

Meeting on Heart Disease.—At a scientific session of the New York Heart Association March 28 the speakers included Drs. Harold E. B. Pardee, on "Uniform Criteria for the Diagnosis of Heart Disease and a Discussion of Special Features of the New Edition of the Criteria"; Clarence E. de la Chapelle, "The Anatomical Changes Produced by Heart Disease," and Charles E. Kossmann, "The Contribution of Electrocardiography to Heart Disease."

Medical Service in Vocational Schools.—The vocational school division of the public school system has established a complete medical unit in each of the twenty-four trade and industrial schools, according to the New York *Times*. Forty physicians and as many nurses have been assigned to watch the health of 55,000 students in these schools. Each child is to have a thorough physical examination and a follow-up system is to check on remediable ailments. Students who cannot afford private treatment are sent to clinics. One physician and one nurse will be on duty as long as classes are in session. The new arrangement is an expansion of previous service. Last year, although not every school had a complete medical staff, 42,000 pupils were examined. Only 10,000 were found to be free from defects. More than 3,500 defects were corrected. Twenty thousand pupils were examined to discover whether they had chosen a vocation to suit their physical capacities; 6,000 were found to be in work unsuited to them. In some the impairments were corrected, but in 1,500 the defects could not be remedied and these children were directed into other fields, it was said.

OKLAHOMA

Society News.—Dr. Philip M. McNeill, Oklahoma City, addressed the Okfuskee-Okmulgee County Medical Society, Okemah, January 18 on pneumonia.——Dr. E. Rankin Denny, Tulsa, addressed the Tulsa County Medical Society, Tulsa, March 13 on "Physiology of Oxygen Want and Clinical Use of Oxygen" and Mr. J. I. Banash, consultant engineer, Chicago, "Methods of Administering Oxygen."

PENNSYLVANIA

Society News.—Drs. William J. Fetter and William L. Mullins, Pittsburgh, addressed the Jefferson County Medical Society, Punxsutawney, March 9 on "Biliary Tract Problems" and "Clinical Aspects of Coronary Artery Disease" respectively.——Dr. Charles Howard Marcy, Pittsburgh, addressed the Mercer County Medical Society, Grove City, March 8 on "Modern Treatment in Tuberculosis."——Dr. George Harlan Wells, Philadelphia, addressed the Delaware County Medical Society, Chester, March 9 on "Comparative Value of Antipneumococcic Serum and Sulfapyridine in the Treatment of Pneumonia."

Philadelphia

The Samuel D. Gross Prize in Surgery.—The Philadelphia Academy of Surgery announces that essays will be received in competition for the Samuel D. Gross Prize of $1,500. According to the conditions, this prize is awarded every five years "to the writer of the best original essay, not exceeding one hundred and fifty printed pages, octavo, in length, illustrative of some subject in surgical pathology or surgical practice founded on original investigations, the candidates for the prize to be American citizens." The competitor who receives the prize shall publish his essay in book form and he shall deposit one copy of the work in the Samuel D. Gross Library of the Philadelphia Academy of Surgery. Essays must be written in English by a single author. Each essay must be typewritten, distinguished by a motto and accompanied by a sealed envelop bearing the same motto, containing the name and address of the writer. The committee will return the unsuccessful essays if reclaimed by the writers or their agents within one year. The committee reserves the right to make no award if the essays submitted are not considered worthy of the prize. The entries should be addressed to the Trustees of the Samuel D. Gross Prize of the Philadelphia Academy of Surgery, care of the College of Physicians of Philadelphia, 19 South Twenty-Second Street, Philadelphia, on or before Jan. 1, 1940.

Pittsburgh

Society News.—Dr. Leo H. Criep addressed the Pittsburgh Otological Society March 6 on "The Relationship of Allergy to Ear, Nose and Throat."——Dr. William F. Braasch, Rochester, Minn., addressed the Pittsburgh Urological Association March 13 on "Unusual Urographic Data."——Speakers before the Allegheny County Medical Society March 21 were Drs. Oliver C. Wenger of the U. S. Public Health Service on "Opportunity for the Physician in a Syphilis Control Program"; Harry I. Miller, "Newer Concepts in the Management of Peripheral Vascular Disease"; Herbert Frankenstein, "Spontaneous Subcutaneous Rupture of the Stomach," and Lawrence Wechsler, "Hematemesis: Problems in Diagnosis and Medical Treatment."

SOUTH CAROLINA

State Medical Meeting at Spartanburg.—The ninety-first annual meeting of the South Carolina Medical Association will be held in Spartanburg April 11-13 at the Hotel Cleveland. The preliminary program includes the following speakers:

Dr. Marion H. Wyman, Columbia, You Can't Socialize a Doctor's Mind.
Dr. Carl B. Epps, Sumter, Shall We Be Leading Pioneers or Driven Slaves?
Dr. Frank Philip Coleman, Columbia, Surgical Management of Pulmonary Tuberculous and Nontuberculous Chest Diseases.
Dr. Keitt H. Smith, Greenville, The Use of Sulfanilyl-Sulfanilamide in the Treatment of Specific Urethritis and Urinary Infections.
Dr. Irwin Grier Linton, Charleston, Vaginal Hysterectomy.
Dr. Sol B. McLendon, Columbia, Epilepsy and Its Management.

Round table conferences will form part of the program. The program lists discussions of deficiency diseases, conducted by Dr. Virgil P. W. Sydenstricker, Augusta, Ga.; roentgenology, Dr. William M. Sheridan, Spartanburg; surgery, Dr. Frederick E. Kredel, Charleston; allergy, Dr. Foster M. Routh, Columbia, and obstetrics, Dr. Robert E. Seibels, Columbia.

TENNESSEE

State Medical Meeting in Jackson.—The annual meeting of the Tennessee State Medical Association will be held in Jackson April 11-13 at the New Southern Hotel under the presidency of Dr. Tom R. Barry, Knoxville. At an evening meeting Tuesday April 11 Dr. Barry will deliver his official address and Dr. Rock Sleyster, Wauwatosa, Wis., President-Elect of the American Medical Association, will discuss "Medical Problems of the Day." Other guest speakers will be:

Dr. James B. McLester, Birmingham, Ala., Pellagra and Its Modern Treatment with Special Emphasis on the Borderline States.
Dr. Fred W. Rankin, Lexington, Ky., Combined Abdominoperineal Resection of the Rectum (talking motion picture in color).
Dr. Clarence H. Crego Jr., St. Louis, Operative Correction of Lower Extremity Length Inequality.
Dr. Leon J. Menville, New Orleans, Breast Cancer: Technic of Examination and Preoperative Radiation.

Tennessee physicians on the program will include:

Dr. Joseph P. Gilbert, Nashville, Epilepsy; Diagnosis and Treatment.
Dr. Henry B. Brackin, Nashville, Metrazol Treatment of Dementia Praecox, or More Frequently Now Called Schizophrenia.
Dr. Horace Barton McSwain, Paris, Auscultation in the Diagnosis of Surgical Diseases of the Abdomen.
Dr. Alfred M. Goltman, Memphis, Manifestations of Allergy Other Than Asthma.
Dr. Robert H. Williams, Nashville, Sulfanilamide Pyridine in the Treatment of Pneumonia.
Lt. Col. George W. Reyer, Medical Corps, U. S. Army, Nashville, The Necessity for Medical Military Preparedness.
Dr. Willis H. Thompson, instructor for the graduate course in pediatrics, formerly of Minneapolis, Feeding Problems in Infancy.

TEXAS

Personal.—Dr. William L. Brown, El Paso, was recently made an honorary member of the Southwestern Medical Association, of which he was a founder twenty-five years ago.——Dr. William S. Terry Jr., Jefferson, was recently appointed health officer of Marion County.——Dr. John C. Blair, Kerens, was recently elected chairman of the state board of education, it is reported.——Dr. Otho C. Bowmer, Corsicana, was recently elected health officer of Navarro County.

District Meetings.—The Twelfth (Central Texas) District Medical Society met in Waco recently. The speakers included Drs. Lewis W. Pollok, Temple, on "Surgical Treatment of Uterovaginal Prolapse"; Harry H. McClellan, San Antonio, "Is Insanity an Inherited Defect or an Acquired Delirium?"; Herbert E. Hipps, Marlin, "A New Surgical Procedure in Acute Arthritis," and Howard R. Dudgeon Jr., Waco, "Primary Thrombocytopenic Purpura Haemorrhagica."——The Tenth District Medical Society in cooperation with the state department of health sponsored a two day graduate course in obstetrics and pediatrics in Lufkin February 9-10. The lecturers were Drs. Calvin R. Hannah and Hugh Leslie Moore, Dallas.

WISCONSIN

State Board Appointments.—Drs. George R. Reay, La Crosse, and Henry W. Howe, Racine, have been appointed to the state board of medical examiners. They succeed Drs. Alvin G. Koehler, Oshkosh, and Henry O. McMahon, Milwaukee.

New Chairman of Cancer Committee.—Dr. Marcos Fernan-Nunez, professor of pathology and bacteriology, Marquette University School of Medicine, Milwaukee, has been appointed chairman of the cancer committee of the State Medical Society of Wisconsin. He succeeds Dr. William D. Stovall, Madison, who recently resigned after ten years of service.

Society News.—Speakers at a meeting of the Milwaukee Pediatric Society February 8 were Drs. John Lester Reichert, Chicago, "Treatment of Nonspecific Vaginitis in Children"; Elmer L. Sevringhaus, Madison, "Endocrine Changes in Adolescence," and John Dale Owen, Milwaukee, "The Physiology of the Vaginal Tract."——Dr. Jacob Arnold Bargen, Rochester, Minn., addressed a joint meeting of the Milwaukee Academy of Medicine and the Milwaukee Gastroenterological Society February 21 on "Regional Enteritis: Pathology, Diagnosis and Clinical Observations."——Speakers before the Medical Society of Milwaukee County February 10 were Dr. Rock Sleyster, Wauwatosa, President-Elect of the American Medical Association, on "Medical Problems of the Day"; Mr. J. C. Gamroth, state compensation officer, Madison, "The U. S. Compensation Act for Injuries to WPA Workers," and Mr. J. George Crownhart, secretary, State Medical Society of Wisconsin, Madison, on "Sickness Insurance."

GENERAL

Special Society Election.—Dr. Samuel W. Hartwell, Buffalo, was elected president of the American Orthopsychiatric Association at its annual meeting in New York in February. Dr. Norvelle C. La Mar, New York, was reelected secretary. The 1940 meeting will be held in Boston.

Warning—Fraudulent Instrument Man.—The American Surgical Trade Association reports that a swindler is operating among Ohio physicians claiming to represent surgical supply houses and collecting in advance for surgical instruments. The firms he claims to represent are nonexistent and the physicians are being swindled, according to the association. Physicians are warned not to pay money in advance to unknown persons.

American Institute of Nutrition.—A symposium on "Fortification of Foods with Vitamins and Minerals" will form the program of the annual meeting of the American Institute of Nutrition in Toronto, Canada, April 26. Speakers in the symposium will be Agnes Fay Morgan, Berkeley, Calif.; Lydia Roberts, Ph.D., Chicago; Dr. William H. Sebrell Jr., U. S. Public Health Service; E. M. Nelson, Ph.D., U. S. Department of Agriculture, Washington, D. C., and Dr. Alonzo E. Taylor, Stanford University, Calif.

April Is "Cancer Control Month."—President Roosevelt has issued the annual proclamation as provided by a law passed in 1938 designating April as "Cancer Control Month" and inviting governors of the states, territories and possessions of the United States to similar action. The proclamation invites all agencies interested in a national program for the control of cancer to unite during April "in a concerted effort to impress upon the people of the nation the necessity for this program and the importance of constant vigilance in this fight for humanity."

Conference of Radiologists.—The American College of Radiology held its ninth annual conference with the Conference of Teachers of Clinical Radiology under the auspices of the commission on education of the college February 12 in Chicago. At an afternoon meeting Dr. Walter F. Donaldson Pittsburgh, spoke on "Medical Economics and the National Scene" and Mr. Mac F. Cahal, executive secretary, The Inter-Society Committee for Radiology, reported on a survey of the economics of radiologic practice. An evening meeting was devoted to discussion of refresher courses for radiologists.

Symposium on Temperature.—The American Institute of Physics announces plans for a symposium on "Temperature and Its Measurement in Science and Industry" to be held this fall. Those interested in taking part in such a symposium should communicate with the institute at an early date, giving information about their field of work and the subject of the contribution that they wish to make. The purposes of the symposium are to (1) coordinate the treatment of the subject in the sciences and branches of engineering, (2) review principles and bring up to date the record of recent work, (3) accumulate contributions for a comprehensive text to be published as soon as possible after the symposium is held, (4) reveal the subject as an important branch of physics and (5) supply schools with the information required for the improvement of curriculums. Among members of the committee arranging the symposium is Dr. Eugene F. DuBois, professor of medicine, Cornell University Medical School, New York. Information may be obtained from the institute at 175 Fifth Avenue, New York. Henry A. Barton, Ph.D., is director.

Meetings at Richmond April 5-7.—The American Association for Cancer Research will hold its thirty-second annual meeting at the Medical College of Virginia, Richmond, April 5-6. Among those who will present papers are:

Dr. Shields Warren, Boston, The Prognostic Value of the Response to Radiation in Carcinoma of the Cervix.

Dr. Kenneth M. Lynch, Charleston, S. C., Carcinoma of the Lung in Asbestosilicosis.

Dr. George O. Gey, Margaret K. Gey and Margaret R. Lewis, Baltimore, Continuous Cultures of Blood Cell Tumors and Their Transplantability.

Wilton R. Earle, Ph.D., and Carl Voegtlin, Ph.D., Washington, D. C, Further Observations on the Mode of Action of Methylcholanthrene on Cultures of Normal Tissues.

The American Association of Pathologists and Bacteriologists will have its thirty-ninth annual meeting April 6-7 at the college. Among more than fifty papers on the program are the following:

Dr. Dale Rex Coman, Philadelphia, Experimental Peritonitis: Alteration of the Leukocytic Response After Repeated Injection of Physiologic Saline.

Drs. David Goldstein and Irving Graef, New York, The Influence of Sulfanilamide upon the Evolution of Experimentally Induced Pneumococcus Pneumonia in Rats.

Dr. Walter Schiller, Chicago, Concepts of a New Classification of Ovarian Tumors.

Dr. Harry Goldblatt, Cleveland, Experimental Observations on the Pathology and Pathogenesis of Essential Hypertension.

Drs. Irvine H. Page, Indianapolis, and Irving Graef, New York, Hypertension Following Experimental Perinephritis Induced by Cellophane.

Drs. Edwin F. Hirsch and Russell H. Morgan, Chicago, The Causal Significance to Traumatic Ossification of the Fibrocartilage in Tendon Insertions.

Dr. Alvin J. Cox Jr., San Francisco, Vitamin A Storage in Active and Arrested Liver Cirrhosis.

The American and Canadian section of the International Association of Medical Museums will hold its thirty-second annual meeting April 5. The program will include a symposium on photographic methods as applied to museum technic and discussions on technical methods and cardiovascular and other anomalies.

FOREIGN

Medical Meetings in Germany.—Announcement is made of medical meetings to be held in Germany within coming months, as follows:

German Ophthalmological Society, Heidelberg, September 4-6.
German Society for Digestive and Metabolic Disorders, Vienna, in September.

Ophthalmologic Tour to the United States.—The North of England Ophthalmological Society is sponsoring an "ophthalmologic tour" to the United States. Visits will be made to New York, Philadelphia and Washington. The group will leave Southampton on the *Nieuw Amsterdam* April 22, arriving in New York April 30, will be in Philadelphia May 5-7 and in Washington May 8-9 and will leave New York on the *Queen Mary* May 10.

Personal.—Dr. James R. Learmonth, regius professor of surgery in the University of Aberdeen, Scotland, has been appointed professor of surgery at the University of Edinburgh

to succeed the late Sir David P. D. Wilkie. Dr. Learmonth received a scholarship from the Rockefeller Foundation in 1924 and spent a year at the Mayo Clinic, Rochester, Minn. After a period in Scotland he returned to Rochester as a member of the surgical staff of the clinic in 1928 and remained there until 1932, when he went to the University of Aberdeen.——William D. Coolidge, Ph.D., director of the research laboratory of the General Electric Company, Schenectady, N. Y., has been awarded the Faraday Medal by the British Institution of Electrical Engineers. Dr. Coolidge is known for his development of the x-ray tube that bears his name, for the production of high voltage cathode rays outside the generating tube, for his work on modern x-ray generating apparatus, measurement of the dielectric constant of liquids and conductivity of aqueous solutions of high temperatures and on ductile tungsten. He has previously received the Hughes Medal of the Royal Society of Arts and Sciences and numerous American awards.

Deaths in Other Countries

Dr. Charles Cyril Okell, editor of the *Journal of Hygiene;* at one time assistant editor of the *Journal of Pathology and Bacteriology,* professor of bacteriology at the University of London College Hospital, died in Cambridge February 9, aged 50.——**Prof. Vaclav Libensky,** professor of medicine and director of the Polyclinic at Charles University, Prague, Czechoslovakia, president of the Czechoslovakian Society of Cardiology, died Dec. 10, 1938.

Government Services

Annual Report on the Health of the Army

For the fifth successive year, automobile accidents have been first in the list of causes of death in the United States Army. According to the annual report of the surgeon general, during the calendar year 1937 of 611 deaths, 329 were caused by disease and 282 by external causes. The death rate, 3.48 per thousand, was the lowest in eleven years. The leading causes were: automobile accidents 102, suicides 59, pneumonia 56, diseases of the coronary arteries and angina pectoris 41, airplane accidents 27, appendicitis 25, drowning 23, cancer and other malignant tumors 22, tuberculosis 17 and homicides 14.

The strength of the army in 1937 was 175,624, about 10,000 more than in 1936. The average officer strength was 11,706.

There were 108,756 admissions to sick report, a rate of 619 per thousand strength of personnel, somewhat lower than the 1936 rate. The infectious diseases proper and common respiratory diseases account for approximately 40 per cent and injuries 20 per cent of the admissions. Five causes, influenza, tonsillitis, bronchitis, injuries due to athletics and gonorrhea, produced 24.4 per cent of all illness in the army. For the army as a whole, the highest incidence of illness was among white enlisted men in Panama, the lowest among Filipinos, but the rate for Negro enlisted men exceeded that for Filipinos only slightly.

Gonorrhea headed the list of causes for loss of time, as it has every year since the World War, accounting for 194,973 days lost; the next in order was athletic exercises, with 68,790 days lost. Communicable diseases and injuries produce nearly half the noneffectiveness. The daily noneffective rate has remained about the same for many years; for 1937 it was 29.7 per thousand of strength.

Retirements and discharges for physical disability were responsible for the separations of 2,651 persons from the service in 1937: seventy-five officers and warrant officers, twenty nurses and 2,556 enlisted men. Officers retired for disability averaged 50.5 years of age and 23.7 years of service, but a large percentage of the enlisted men were young and had served only a short time. In 91.4 per cent of the enlisted men the disability existed prior to enlistment. The leading cause of discharge as for several years past was dementia praecox. The tendency to this disease is inherent in many persons, but a satisfactory method of preventing them from enlisting in the army has not yet been devised, the report comments. As much may be said of tuberculosis and constitutional psychopathic states, which were third and fourth on the list of causes for discharge. In the case of flat foot, however, which was second on the list, it would seem that the standards of physical examinations should be more rigidly adhered to at the time of enlistment, in the opinion of the surgeon general.

Venereal diseases are costing the army more than a million and a half dollars a year for treatment and are responsible for 18 per cent of the noneffectiveness due to disease. Although conditions with respect to these diseases have improved greatly, no reason is seen for relaxation of control measures; rather they should be strengthened, the report said.

Pneumonia was the leading cause of death among diseases, as it was in 1936. There were 871 cases. Influenza increased, as it has each year since 1933; in 1937 there were 7,226 admissions for this cause. Admissions for tuberculosis reflect the downward trend in the general population, it was pointed out; there were 271 admissions, 170 discharges for disability and 17 deaths in 1937. An abrupt increase in typhoid was noted, fourteen cases compared with four cases in 1935 and 1936. There were no cases of rabies, anthrax, tetanus or smallpox.

Diseases of the digestive system caused more admissions to sick report than any other. Tonsillitis and pharyngitis are included in this group and caused 40 per cent of the admissions. Appendicitis showed the highest admission rate in ten years, with 2,224 admissions, 2,100 appendectomies and twenty-three deaths.

More than 900 men were absent from duty each day, on the average, during 1937 because of injuries. This amounted to 18 per cent of all admissions to sick report and 19 per cent of the noneffectiveness. Athletics, falls and automobiles were responsible for 43 per cent of the cases. The report predicted that as the use of motor vehicles increases in the army injuries and deaths caused by them will increase. Military vehicles were involved in only eleven of the 102 deaths, but the number was twice as large as in 1936, it was pointed out.

It is believed that carelessness is the chief factor in automobile accidents and falls. Lack of care in selection of athletes, in provision of equipment and in the maintenance of playing fields may contribute to athletic injuries, the report suggested.

The number of persons invalided home from overseas garrisons was 840, twenty-one of whom were officers. Diseases of the circulatory system were responsible for one third of the cases among officers; among enlisted men the principal causes were flat foot, venereal diseases, dementia praecox, constitutional psychopathic states, psychoneurosis and tuberculosis.

The patient-day cost for the fiscal year 1938, computed on figures furnished by Walter Reed, Fitzsimons, Letterman, Army and Navy and William Beaumont General hospitals and the station hospital at Fort Sam Houston, Texas, was $5.09. The number of beds available and occupied in general hospitals June 25, 1938, was 5,359.

With the addition of fifty medical officers authorized by Congress in 1937, the present commissioned personnel is 1,083. The enlisted strength of the medical personnel as of June 30, 1938, was 8,291. The Medical Department Reserve Corps had a strength of 15,061 June 30.

Recent efforts to modernize the equipment of the medical department have been directed toward development of a mobile surgical hospital. Four semitrailers with van type bodies have been procured. Two of these are being fitted as operating room vans, one as a sterilization unit and one as a kitchen. It is hoped to add an additional van to complete a basic operating unit in order that the complete equipment may be demonstrated at the International Congress of Military Medicine and Pharmacy in May in Washington and later at the New York World's Fair.

During the year of this report a new main hospital building was completed at Fort Sam Houston at a cost of $1,347,400. A fund of $200,000 was appropriated for a hospital of 116 beds and barracks for the medical detachment at Fort Knox, Kentucky.

A section on syphilis was established in the professional service division of the surgeon general's office, with Major L. L. Gardner in charge. The Army Medical Museum reported 4,491 accessions during the year, an increase over previous years. The report says that the museum has taken its place as one of the popular sights of Washington and 100,781 persons visited it in the year. Loan sets of slides from the registry of pathology in the various specialties are in constant demand, especially by physicians preparing for the examinations of the boards of medical specialties. The Army Medical Library added 4,104 bound volumes to its collection and finished the third volume of the fourth series of the Index Catalogue. The fourth volume containing literature catalogued under the letter D was reported to be under way. Congress authorized construction of a new building for the museum and the library, but funds were not appropriated.

March 1, 1939.

Report of the Medical Research Council

Twenty-five years ago the government decided to promote medical research by setting up the Medical Research Committee, which in 1920 became the Medical Research Council. The report for 1937-1938 refers to the great increase in medical investigation in this period, to which is due an improved level of health. The whole trend of medicine in the present century has been toward study of the basic factors of disease, and many maladies can now be cured or controlled by specific remedies. But there is often delay in the application of discoveries.

THE PREVENTION OF DIPHTHERIA

A striking example is the lack of public recognition of the value of preventive inoculation against diphtheria, which is the commonest single cause of death among children. In 1937 there were 61,339 cases in England and Wales, with 2,963 deaths, nearly all in children between the ages of 1 and 15 years. Yet since 1929 preventive inoculation has proved increasingly successful and in parts of America diphtheria has practically disappeared. In Hamilton, Ont., with a population of 175,000, diphtheria has not been diagnosed once in the past five years, while in Quebec, where inoculation was not used, the deaths from diphtheria were even more numerous in 1936 than in 1927. In New York City inoculation has reduced the mortality for diphtheria in children to 2.1 deaths per hundred thousand persons, while the figure was 31.8 in England and Wales.

CHRONIC PULMONARY DISEASE AMONG COAL MINERS

In recent years it has become apparent that coal miners are subject to disabling chronic pulmonary disease that does not come within the accepted definition of silicosis, which it resembles clinically but from which it differs radiologically. In silicosis the lungs, on radiologic examination, show shadows indicating distinct nodulation, but in the condition referred to this appearance is absent and instead there may be a variety of other shadows, the significance of which, in relation to the occurrence and progress of disability, is not clearly understood. Apart from the disabling character of the disease, the matter is of economic importance, for compensation is given for silicosis but not for other forms of pulmonary disease. The council has undertaken to investigate the subject for which it has chosen the anthracite coal field of South Wales. The problem is difficult, for pulmonary disease among coal miners cannot easily be related to particular working conditions, as there are so many factors which vary from place to place. The council is gratified to be responsible for a fine example of team work, which involves the cooperation of physicians, chemists, physicists, statisticians, geologists and mine inspectors.

THE RADIUM TREATMENT OF CANCER

Until recently the only ways to apply radium were interstitially or to the surface. A newer method, known as radium beam therapy or teleradium therapy, consists in the use of rays from a large mass of radium situated at a distance from the patient. In 1933 the council cooperated with the Royal Colleges of Physicians and Surgeons, the National Radium Commission and the Radium Institute in forming the Radium Beam Therapy Research. During the first four years of the research the use of the method was restricted to the treatment of cancer of the mouth, tongue, pharynx and larynx, in which the results have been encouraging. These sites were selected for the preliminary observations because they are accessible to radium therapy and, being comparatively superficial, permit the local effects of radium to be observed readily. In most of the cases the condition was advanced and the results compare favorably with the results of surgical intervention. On the other hand, the treatment produces a period of discomfort. New technical methods have been evolved through the cooperation of physicists and clinicians. It is clear that the method is capable of destroying accessible primary growths, and the main problem is a method for insuring the destruction of secondary growths. After a course of irradiation with a 5 Gm. unit, secondary growths usually disappear from the neck but, if present in the chest, escape destruction. In order to meet the situation work has recently been begun with a 10 Gm. unit. It is proposed to make a comparative study of the radium beam therapy and the high voltage roentgen therapy of cancer. Meanwhile there is already looming in the distance the therapeutic effect of neutrons and of temporarily radioactive substances, such as radiosodium. It is possible that both radium and the x-rays will be superseded by the cyclotron in the treatment of cancer by radiation and radioactive substances. Dr. F. G. Spear of the council's staff is at present in California, working with Professor Lawrence on the biologic effects of neutrons.

Ophthalmologic Congress

The annual congress of the Ophthalmological Society of the United Kingdom will begin April 20. Ophthalmologists from abroad are invited to all the meetings. Immediately preceding the congress, meetings will be held at the Royal Society of Medicine, 1 Wimpole Street, London, by the International Association for the Prevention of Blindness and the International Organization Against Trachoma. The International Association for the Prevention of Blindness will convene on April 19 at 2 p. m., and the application of the Credé method for the prevention of ophthalmia neonatorum in various countries will be discussed by speakers from home and abroad, including Dr. Conrad Berens of New York. The International Organization Against Trachoma will meet on April 19 at 4:30 p. m. to discuss the incidence and clinical type of trachoma in Europe and North and South America, that is in countries commonly considered to be nontrachomatous, and the treatment of trachoma by sulfanilamide and its congeners. Members of the congress are invited to these meetings.

A War Time Hospital Organization

Britain entered the great war without any military preparations for a catastrophe of that magnitude. If unhappily she should have to defend herself against aggression, she will be found to have made every possible preparation, especially for air attacks on the civilian population. The minister of health, Dr. Walter Elliot, has issued to all hospital authorities a memorandum explaining a comprehensive emergency scheme for a wartime hospital organization. In the course of the next few weeks every hospital will receive a notification explaining what part it is to play. The minister has been assisted by specialists appointed in accordance with the advice of the presidents of the Royal Colleges of Physicians and Surgeons. The basis of the scheme is the division of hospitals into different classes according to their intended uses. Room is to be made for the reception of casualties in one wing or block of most of the mental hospitals in the country, and a few mental hospitals are to be completely cleared of their ordinary patients, who will be transferred to other institutions, so as to provide some major units for the reception of casualties from the largest cities. It is proposed to link up casualty hospitals to each other in the more vulnerable areas and to selected hospitals farther out. The casualty hospitals would include the leading London hospitals, which would be denuded of their ordinary patients. Some of the institutions which are to act as base hospitals are to receive part of the valuable equipment now concentrated in the cities.

There are 371,500 hospital beds in England and Wales, not including 130,000 in mental hospitals. As these beds are almost

always fully occupied with the ordinary civilian sick, they would have to be substantially increased in the event of an emergency. At the outset there will be sent home all patients for whom institutional treatment is not essential except those whose homes are in areas to be evacuated. It is estimated that this would free from 30 to 50 per cent of the existing beds. In addition, patients in the danger areas would be transferred to outer areas and additional beds would be introduced into selected hospitals and institutions. Arrangements for distributing 80,000 beds are already in hand. If necessary, accommodation can be found by putting beds closer together in wards or by setting up others in ancillary buildings within hospital precincts. The effect would be to provide 300,000 beds for casualties, of which 200,000 would be available in the first twenty-four hours. But the minister appreciates that this may not be sufficient, and the government is exploring the possibility of using additional buildings for the expansion of hospitals in the danger areas and erecting huts on land adjacent to hospitals elsewhere.

Under the affiliation scheme the medical staffs of groups of affiliated hospitals will be divided into surgical teams and teams to be assigned to the appropriate hospitals. There are to be mobile surgical teams to deal with exceptional pressure wherever it may come. Where personnel is required beyond what can be given by affiliated hospitals, requests are to be made to the ministry of health and the Central Emergency Committee of the British Medical Association, which has already established a register of all physicians available. In advance of an emergency, individual doctors will be allotted to particular hospitals or groups of hospitals.

The Cancer Bill: Quack Advertising to Be Checked

In the House of Commons the minister of health, Dr. Elliot, stated that he proposed to appoint a subcommittee of the medical advisory committee to advise him on general principles with regard to the treatment of cancer. This subcommittee would consist of experts in surgery, medicine, gynecology, radium therapy, pathology and public health administration. A member moved amendments to strengthen the clause against the advertising of remedies for cancer. The prohibitory clause in the bill applied only to the person offering treatment and not to those who aided or abetted by the advertising. As pointed out in the *Times*, a quack residing outside the jurisdiction of English courts could order an advertisement by post and no one would be liable. All reputable newspapers had long refused to publish such advertisements and the others should be compelled to do so. For this reason the Newspaper Society had expressed complete approval of the amendments. These were passed by the house.

PARIS

(From Our Regular Correspondent)

Feb. 25, 1939.

The French League Against Rheumatism

The annual meeting of the French League Against Rheumatism was held in Paris Dec. 3, 1938. At the morning session operations for chronic rheumatic arthritis of the hip and gonorrheal rheumatism were demonstrated by Professor Mathieu and Dr. Padovani, who also showed a color film of arthroplastic resection of the hip.

At the afternoon session, papers were read on chronic gonorrheal rheumatism. The first of these was presented by Prof. Henri Gougerot, Florent Coste and Pierre Durel, who said that the chronic forms were not as well known as the acute forms. A striking feature of the chronic forms was that the relation between former gonorrhea and the arthritis was not always apparent. Frequently the existing arthritis seemed to be more directly related to acute nonspecific articular rheumatism, an intestinal infection, syphilis or tuberculosis.

In the second paper, Dr. F. Layani called attention to the nonspecific character, in general, of the treatment. For severe polyarthritis, drugs which act by raising the temperature are indicated, whereas for the subacute forms, preparations containing gold, as well as the neoarsphenamines, acridine salts and subcutaneous bacteriotherapy, have given satisfactory results. The use of the sulfanilamides has not been encouraging. Chronic gonorrheal rheumatism can never be controlled until local foci have been eliminated. If this can be accomplished by using the sulfanilamides and artificial heat, the affected joints should be massaged and given the benefit of early mobilization.

In a third paper, Drs. J. Surmont and G. Michon outlined the various types of physical therapy. For the localized forms of chronic gonorrheal arthritis, radiotherapy to combat the inflammatory reaction should be given. For the more generalized forms with acute or subacute onset, pyretotherapy with a temperature to 41 C. (105.8 F.) is indicated. When the onset has been more chronic, either irradiation in high doses or short wave treatment, also in high doses, gives the best results. In general the various forms of physical therapy should be employed.

In a fourth paper, Dr. Marcel Boppe said that before any operative correction of ankylosis was contemplated it was essential to eliminate a persisting urogenital or arthritic infection. Arthroplasty, especially of the knee, has been followed by excellent functional results, even though the radiographic changes, such as those of a degenerative hypertrophic osteoarthritis, are demonstrable postoperatively.

Jacques Forestier and Mlle. Certonciny reported having found evidences of a preceding gonorrheal infection in 44 per cent of fifty cases of spondylo-arthritis.

Dr. M. Pellet stated that, from the radiologic standpoint, gonorrheal arthritis fails to show any characteristic changes. One must consider rarefying osteitis, with hyperostosis and osteophytosis and numerous other changes in relation to the clinical history and laboratory observations.

Dr. Graber-Duvernay recommended the use of calcium gluconate for chronic gonorrheal coxitis. Several series are given of fifteen injections of 10 cc. of a 10 per cent solution, at the rate of five injections a week. After four or five such series no additional injections are given for a month.

Electrocardiographic Changes Due to Barometric Depression

The experimental study of the effects on the cardiovascular system of lowering of the atmospheric pressure as encountered by aviators at high altitudes is being carried out on an extensive scale at several of the aviation centers near Paris. Animals are placed in pneumatic caissons and the oxygen tension is lowered as needed so as to reproduce as closely as possible the atmospheric conditions met in aviation. At the Jan. 17, 1939, meeting of the Académie de médecine of Paris, the three cardiologists Prof. Charles Laubry, Dr. Jean Walser and Dr. Louis Deglaude reported their observations on dogs and rabbits on the electrocardiographic changes incident to atmospheric conditions at different altitudes. Their results differ in some respects from those published by other investigators.

At high altitudes, modifications of the monophase wave type as reported by Koch were never observed. After exposure to conditions similar to those found at altitudes of 10,000 meters, Cluze and his co-workers reported total cardiac fibrillation. This could not be corroborated by Laubry and his co-workers, who believe that their observations differ from those of the other investigators cited in the form and dose of the anesthetic which was employed and in the duration of the exposure to various altitude conditions.

The artificially produced electrocardiographic changes provoked by the same alterations of pressure under identical conditions are inconstant. The variations of the T wave are more constant. At an altitude of 1,500 meters, there is a slight increase of amplitude, which usually diminishes at altitudes between 4,000 and 8,000 meters, to increase when an altitude of 10,000 meters is reached. It then increases to such an extent that it can exceed in amplitude that of the R wave. The heart appears to possess a remarkable adaptability to sudden changes in atmospheric pressure as observed in almost vertical upward flight. The more important alterations of the electric curve are observed in experimental depressions which correspond to altitudes above 8,000 meters (about 25,000 feet), especially when an airplane is obliged to remain at that altitude for a prolonged interval.

Birth Rate Continues to Decrease

The population of France showed a sharp decline during the first nine months of 1938 according to official statistics. Deaths exceeded births by 27,365, while in 1937 there were eleven more births than deaths. The number of marriages decreased from 202,811 in the first nine months of 1937 to 200,160 in the same period of 1938. The number of deaths increased from 471,139 in the first nine months of 1937 to 494,107 in the same period of 1938. This increase in mortality is chiefly responsible for the decrease in the natality rate, i. e. relation of births to deaths, because there were 471,150 births in the first nine months of 1937, as compared with 466,742 births in the same period of 1938.

Effects of Alcohol, Coffee and Tobacco on Motorists

Among motorists it is frequently assumed that the harmful effects of alcoholic beverages can be abolished by the drinking of coffee. Professor Dr. Mueller, director of the Institute of Forensic Medicine of Heidelberg University, has determined from numerous experiments that this opinion is completely wrong. The persons submitting to the tests drank substantial quantities of beer and then partook of very strong coffee (40 Gm. of coffee beans of superior quality in 400 cc. of boiling water, allowed to stand for fifteen minutes). Subsequent tests in no instance disclosed any change in the alcoholic content of the blood. However, further observation of the subjects showed an alleviating influence on the subjective and objective effects of alcohol. This was manifested from fifteen to thirty minutes after ingestion of the coffee; the subjects no longer felt fatigued, the gait was steadier and indistinct speech had disappeared. Then too the reaction time, namely the interval between the observation of a circumstance and the necessary response, was diminished, although the normal interval was not reached. However, later on after the consumption of coffee, the subjects experienced a pronounced feeling of relaxation and uncertainty, which rendered them unfit for further experimentation. According to these tests the drinking of coffee produced only a rather brief recovery. If the subject was accustomed to coffee drinking, the diminution of the sobering effect was remarkable. By and large, if coffee sobered an erstwhile intoxicated person, the sobriety was of brief duration and was followed by such pronounced relaxation that, as Mueller says, one can by no means assume the responsibility for permitting drivers of motor vehicles to indulge freely in alcoholic beverages on the assumption that they can be sobered by subsequent drinking of coffee. The sobering effect of coffee may be explained as due to the contraction of the cerebral vessels and consequent diminished blood perfusion of the brain and the central nerve cells.

Whereas caffeine produces a remission of the signs of alcoholic intoxication, the nicotine contained in tobacco seems to exacerbate the effects of alcohol. The basis for this circumstance is assumed to be a dilatation of the cerebral vessels, and this in turn, on account of the concomitant increase in blood perfusion, leads to a concentration of alcohol in the nerve cells. If coffee drinking after consumption of alcohol is accompanied by the smoking of cigarets, the sobering effect of the coffee will be in large part offset by the nicotine.

The Pharmacology of Short Waves

Fritz Hildebrandt, professor of pharmacology at Giessen, conducted investigations of the pharmacology of short waves. Previously only an increased thermic effect in the tissue was demonstrated. Since it is to be assumed that chemical processes are also produced, the author first examined the histamine content of the blood after treatment with the short wave apparatus according to Schliephake's method (wavelength 3.5 meters). These experiments were performed on dogs; the thorax was exposed to the short wave current for from one half to one hour. At various intervals within the next twenty-four hours, specimens of blood were taken and the histamine content was determined. In some of the animals an increase of several hundred per cent was observed to take place directly and a return to normal would occur within the next two to four hours. In others the histamine value was not elevated immediately, but rather the maximum was reached after some two hours and the return to normal value then ensued gradually in the next few hours. Diathermic tests yielded virtually the same results. Accordingly the influence of the histamine content of the blood must be attributed to the pronounced thermic effect of the short wave current. The histamine values should be rather large, since tests in which single injections of histamine were used in doses of 0.1 mg. per kilogram of body weight disclosed that the histamine had disappeared quantitatively from the blood at the end of five minutes.

Regulation of Radioactive Waters

New legislation provides for strict regulation of the advertising of the products of those medicinal springs which are entitled to be termed "radiumbäder" (radium baths). Proprietors of such springs are required to measure the radioactivity of all spring water and other medicinal products which are advertised as radioactive. These tests must be made at regular quarterly intervals corresponding to the seasons of the year. All advertising matter published since Jan. 1, 1939, relative to radioactive therapeutic substances must contain exact numerical data on the radioactivity of the products. The proper figure should be reckoned as the average of at least four measurements made within a certain year and at all seasons of the year. Thus it is not permissible to furnish numerical data with regard to medicinal springs which, although literally accurate, fail to take into account the natural variations in radioactivity.

Professor Schoen Called to Göttingen

As previously reported, Prof. Hermann Straub, Göttingen ordinarius of internal medicine, died suddenly of heart disease while traveling. Now called to succeed him is Prof. Rudolf Schoen, Leipzig ordinarius and director of the university policlinic of internal medicine. Professor Schoen is 47 years old and has had a distinguished training. He is a pupil of pathologist Borst, pharmacologist Wieland, internist Ernst von Romberg and, in particular, internist Morawitz. When the last named left Würzburg for Leipzig, Schoen went with him. Schoen's works deal with pharmacologic-clinical topics, for example problems of sleep, as well as with studies in pathologic physiology. As the director of the clinic at Göttingen has always been a distinguished internist, the choice of Schoen represents a signal recognition of his achievements.

The Number of Cremations

In the German reich during 1937, a total of 78,332 cremations took place in 117 crematories. This means that the cadavers of 9.9 per cent of all persons dying in that year were incinerated.

Professor Weygandt Is Dead

Wilhelm Weygandt, for many years a psychiatrist in Hamburg, died at the age of 68 at Wiesbaden, where he had lately resided. When Weygandt decided to devote himself to psychiatry he had already acquired an unusually broad educational background, for he had been a student of theology, philosophy, psychology, languages and art. From 1896 he specialized in psychiatry and contributed importantly to this field. After extensive travel in connection with his studies, he became extraordinary professor in Würzburg in 1904 and in 1908 became director of the great Hamburg-Friedrichsberg hospital. At the foundation of Hamburg University in 1919, Weygandt was appointed to the chair of psychiatry. He concerned himself with many problems of his special field and published numerous works, some of which extended into other domains. He was most highly regarded abroad for his work on juvenile feeblemindedness.

BUCHAREST

(From Our Regular Correspondent)

Jan. 23, 1939.

Plethora of Physicians in Sofia

Sofia, the capital of Bulgaria, has a population of 250,000 and there are 800 registered practicing physicians. Accordingly the proportion of physicians to population is 1 : 311. Since there is a shortage of physicians in the rural districts, the government contemplates having one district physician, paid by the state, in each area with a radius of 23 miles.

The System of Medical Chambers

The Albanian legislature has drafted a bill which regulates medical practice and which is destined to introduce into Albania the system of medical chambers. Formerly the quacks, here called "hodjas," could operate freely, but the new law proposes imprisonment and fines ranging from $25 to $100.

Doctor Honoris Causa

At the university of Bordeaux Nov. 29, 1938, Constantin Daniel, member of the Scientific Academy of Paris and Rome, received the degree of doctor honoris causa. Professor Daniel is of Rumanian origin and is well known in France as a surgeon whose literary work aroused great interest in the entire medical world. On this occasion he lectured on scientific cooperation between France and Rumania and between the Bordeaux and Bucharest universities. He also gave an address on the influence which French medical science has had on medical science in Rumania.

Registration of First Year Medical Students

A matriculation certificate is necessary for admission to medical courses, and a foreign certificate is valid only when the minister of public instruction finds it equivalent to the domestic certificate, which embraces the subjects taught in the Rumanian secondary schools. Admission to the first year is temporary, as this year is regarded as a trial year. To qualify for admission the applicant must hand to the dean of the faculty (1) a birth certificate, (2) a certificate of citizenship, (3) a certificate of matriculation, (4) in the case of those under age, the written approval of parents or guardians, (5) a health blank issued by the hygienic institute of the faculty, and (6) the choice of curriculum as well as Bucharest address and three photographs. Admission is preceded by examinations, conducted by a committee of three members appointed by the council of the faculty, in physicochemistry, zoology, botany, anatomy, the physiology of man and general biology, but only from the material prescribed for the upper classes of the secondary schools. These examinations are written and oral. For the written examinations two hours is allowed. Those who pass are admitted only if there are accommodations, as the number of first year students is limited. The examination fee is 100 lei (about $1). Recently a number of families returned from America with sons who were born in the United States and had attended grammar and secondary schools there. Such young men need to learn perfect Rumanian before applying for admittance.

Colon Bacillus Infections of the Urinary Passages

In the experience of the Cluj urologic clinic, mandelic acid has been found highly efficacious against the colon bacillus. Recovery has taken place in 85 per cent of the cases. Among twenty-three cases, treatment of from three to four days was sufficient in seventeen cases, of five days in four cases and of eight days in two cases until the subjective symptoms completely and the objective symptoms almost entirely abated. The patients tolerated ammonium mandelate much better than calcium mandelate. Prior to taking the medicine it is advisable to eat a piece of bread or biscuits, as the drug on an empty stomach is likely to cause discomfort in the stomach. Given in milk or cocoa the drug is not only more palatable but is much better borne. The dose employed at the clinic in general is 12 Gm. daily, but even 9 Gm. a day has proved efficacious. An implicit requirement is limitation of fluids. The period of treatment can be decidedly shortened by reducing the daily quantity of urine to from 500 to 800 cc. In the experience of the chief urologist, mandelic acid therapy is harmless. Renal conditions affecting the renal parenchyma with limitation of renal function contraindicate the use of mandelic acid.

Marriages

JEREMIAH W. KERNER, Jersey City, N. J., to Miss Jeannette V. Hermann of Omaha in Los Angeles, January 20.

COLUMBUS HASSELL PORTER, Memphis, Tenn., to Miss Mary Katherine Ashley at Marion, Ark., Dec. 13, 1938.

WILLIAM HENRY TURNLEY, Stamford, Conn., to Mrs. Hetia Hoffman Stanhope at Riverside, March 2.

LAWRENCE SHINABERRY, Fort Wayne, Ind., to Miss Isabelle McMahan of Alexandria, Nov. 30, 1938.

FRANCIS H. KEHLNHOFER, Wauwatosa, Wis., to Miss Mildred Moldenhauer of Lake Geneva, January 7.

THOMAS ALEXANDER PETERSON, Savannah, Ga., to Miss Ruth Houston of Slyvester, Dec. 3, 1938.

LANDON BOYCE SNAPP, Bristol, Tenn., to Miss Jennie Wood Meade of Mendota, Va., February 18.

HAROLD O. SCHNEIDER, Monroe, Wis., to Miss Frances Louise Warner of Lincoln, Neb., January 7.

CLEMENT E. LOCKWOOD, Holly, Mich., to Mrs. Elsie Knisley of Romeo, in Fenton, Nov. 5, 1938.

ROBERT L. ARMINGTON to Miss Maryanna Loidl, both of Anderson, Ind., Nov. 10, 1938.

JESSE M. SHACKELFORD to Miss Bertha Bowles, both of Martinsville, Va., February 9.

ROY M. PEACOCK, Mobile, Ala., to Miss Mary Belle Forrest of Baltimore, Dec. 20, 1938.

MARY ELLEN NEVILLE to Mr. Edward Bielefeld, both of Milwaukee, Dec. 31, 1938.

JACK MCKITTRICK to Miss Mary Seal, both of Washington, Ind., Nov. 20, 1938.

CHARLES N. LEWIS to Miss Mildred Lee, both of Madison, Wis., Dec. 30, 1938.

Deaths

Daniel Percy Hickling ⊕ Washington, D. C.; Georgetown University School of Medicine, Washington, 1884; professor of psychiatry and neurology and formerly clinical professor at his alma mater; an Affiliate Fellow of the American Medical Association; member of the American Psychiatric Association, Washington Society for Mental and Nervous Diseases, National Psychopathological Association and the Washington Academy of Sciences; member of the committee on arrangements of the International Congress of Mental Hygiene; alienist for the District of Columbia, 1914-1933; professor of medical jurisprudence, National University Law School; formerly attending specialist, neuropsychiatric service, U. S. Veterans Bureau; served as contract surgeon for the U. S. Army; aged 75; served in various capacities on the staffs of the Providence Hospital, Gallinger Municipal Hospital, St. Elizabeths Hospital and the Georgetown University Hospital, where he died, January 10, of pneumonia, following the amputation of a leg.

Elwood Emerson Downs ⊕ Woodbury, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1913; representative of the Section on Radiology to the Scientific Exhibit of the American Medical Association; past president and secretary of the Gloucester County Medical Society, and in 1938 received the society's medal of honor for his contributions as poet laureate of the physicians of Gloucester County; fellow of the American College of Radiology; past president of the Philadelphia Roentgen Ray Society and the Radiological Society of New Jersey; member of the American Roentgen Ray Society and the Radiological Society of North America; president of the board of education; radiologist to the Underwood Hospital, Woodbury; Jeanes Hospital, Philadelphia, and the Salem (N. J.) County Memorial Hospital; author of numerous articles; aged 48; died suddenly, March 18, of embolism following an appendectomy.

George Van Ness Dearborn, Maplewood, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; member of the American Psychiatric Association, American Philosophical Society, American Psychological Association and other scientific societies; in 1899 assistant in physiology at the Harvard University Medical School, Boston; at various times professor, and director of the laboratory of physiology, Tufts College Medical and Dental schools; consulting psychologist to the Forsyth Dental Infirmary for Children, Boston; served during the World War; on the staffs of various veterans administration facilities; at one time on the staffs of the Boston City Hospital and the Augusta (Me.) State Hospital; author of "Textbook of Human Physiology," 1908; editor of "Psychological Index"; aged 69; died, Dec. 12, 1938, in New York.

Carl Boettiger ⊕ Flushing, N. Y.; Cornell University Medical College, New York, 1903; member of the House of Delegates of the American Medical Association in 1935-1936; fellow of the American College of Physicians; member of the Society of American Bacteriologists and the American Society of Clinical Pathologists; past president of the Medical Society of Queens County; served during the World War; clinical professor of medicine at the New York University College of Medicine; member of the city board of health; visiting physician to St. John's Long Island City (N. Y.) Hospital and the Mary Immaculate Hospital, Jamaica, N. Y.; visiting physician and director of the medical service, Queens General Hospital; aged 59; died, February 1, at his home in Forest Hills of coronary thrombosis.

Donald Maclean ⊕ Reno, Nev.; University of Edinburgh Faculty of Medicine, Edinburgh, Scotland, 1898; fellow of the American College of Surgeons; past president of the Washoe County Medical Society; veteran of the Spanish-American War; surgeon for the Leadville, Colo., mines, 1900-1905; chief medical advisor of the Nevada Industrial Commission, 1913-1927; physician to the Nevada State Prison, 1910-1923; surgeon for the Nevada State Orphans' Home; chief of the staff of St. Mary's Hospital; member of the board of trustees of the Washoe General Hospital; aged 66; died, January 4, of coronary thrombosis.

Ellison Lloyd Ross ⊕ Waukegan, Ill.; Northwestern University Medical School, Chicago, 1918; professor of otolaryngology at his alma mater; member of the American Academy of Ophthalmology and Oto-Laryngology and the American Otological Society; fellow of the American College of Surgeons; attending otolaryngologist to the Passavant Memorial Hospital, Chicago, and Veterans' Administration Facility, North Chicago; on the staffs of the Victory Memorial and St. Therese's hospitals, Waukegan; aged 57; died, Dec. 21, 1938, of heart disease.

Byron Ulysses Richards ⊕ Pawtucket, R. I.; Dartmouth Medical School, Hanover, N. H., 1893; an Affiliate Fellow of the American Medical Association; formerly commissioner of health, state registrar and executive secretary of the Rhode Island State Board of Health; past president of the Federation of State Medical Boards of the United States; formerly vice president of the State and Provincial Health Authorities of North America; for many years police surgeon and city physician; aged 72; died, February 15, of mitral insufficiency.

William Cosgrove Hunsicker, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1895; clinical professor of urology at his alma mater; fellow of the American College of Surgeons; director of health of Philadelphia; for many years member of the state senate; urologist to the Hahnemann Medical College and Hospital, St. Luke's and Children's hospitals, Philadelphia, Homeopathic State Hospital, Allentown, and consulting urologist to the Pottstown (Pa.) Homeopathic Hospital; aged 65; died, January 10, of heart disease.

Harry Stearns Willard ⊕ Paterson, N. J.; New York Homeopathic Medical College and Hospital, New York, 1896; fellow of the American College of Surgeons; past president of the Passaic County Medical Society; for many years member of the board of education of Ridgewood; ophthalmologist to the "Bergen Pines," Oradell; Paterson General Hospital and Paterson Eye and Ear Infirmary, Paterson, and Good Samaritan Hospital, Suffern, N. Y.; aged 62; died, Dec. 11, 1938, at his home in Ridgewood of chronic myocarditis.

Ephraim Roland Mulford ⊕ Burlington, N. J.; University of Virginia Department of Medicine, Charlottesville, 1903; member of the House of Delegates of the American Medical Association, 1929-1937; past president of the Medical Society of the State of New Jersey and the Burlington County Medical Society; was surgeon to the Pennsylvania Railroad in his district; on the staff of the Burlington County Hospital, Mount Holly; aged 58; died, March 10, of coronary occlusion while visiting friends in Charlottesville, Va.

Joseph Manuel Rector ⊕ Jersey City, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; attending gynecologist to the Jersey City Medical Center; connected with the Jersey City Hospital since 1893; member of the state board of medical examiners; consulting surgeon gynecologist to the North Hudson Hospital and New Jersey State Hospital at Greystone Park; served during the World War; aged 71; died, January 10, of arteriosclerotic heart disease.

Lyman Augustus Brewer, Toledo, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887; member of the Ohio State Medical Association; fellow of the American College of Surgeons; at one time dean and professor of surgery, Toledo Medical College; served during the World War; chief of staff, Mercy Hospital; consulting surgeon to the Women's and Children's Hospital; on the staff of St. Vincent's Hospital; aged 72; died, January 16, of heart disease.

Mary O'Malley, Buffalo; Niagara University Medical Department, Buffalo, 1897; fellow of the American College of Physicians; past president of the Medical Women's National Association; associate in psychiatry at the George Washington University School of Medicine, 1922-1929; formerly clinical director in charge of the women's service at St. Elizabeths Hospital and consultant in psychiatry at the Gallinger Municipal Hospital; aged 71; died, January 30, of cerebral hemorrhage.

Leopold Jaches ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1903; formerly a lawyer; clinical professor of radiology at his alma mater; member and past president of the American Roentgen Ray Society; member of the Radiological Society of North America and American College of Radiology; served during the World War; aged 65; on the staff of the Mount Sinai Hospital, where he died, January 23.

Martin E. Sargeant ⊕ Ticonderoga, N. Y.; University of Vermont College of Medicine, Burlington, 1908; at various times health officer of the towns of Putnam, Hague and Ticonderoga; health examiner in the local schools, and also acted in a similar capacity in the schools at Putnam and Hague; formerly on the staff of the Moses Ludington Hospital; aged 53; died, Dec. 30, 1938, of pulmonary tuberculosis and diabetes mellitus.

Louis Franklin ⊕ Jersey City, N. J.; Columbia University College of Physicians and Surgeons, New York, 1903; fellow of the American College of Surgeons; surgeon to the Margaret Hague Maternity Hospital and co-founder and president of staff of the Fairmount Hospital, Jersey City; president of the staff of the Hudson County Hospital, Secaucus; aged 56; died, Dec. 20, 1938, of heart disease and hypertensive nephritis.

Ralph Dumphry Simons ⊕ Gardiner, Maine; Medical School of Maine, Portland, 1899; past president of the Kennebec County Medical Society; member of the board of registration of medicine; formerly member of the state legislature; for many years school physician; aged 61; on the staff of the Gardiner General Hospital, where he died, Dec. 25, 1938, of intestinal obstruction due to adhesions.

Edward S. Newell ⊕ Pelham Manor, N. Y.; University of the City of New York Medical Department, 1892; on the courtesy staff of the Mount Vernon (N. Y.) Hospital since 1910, and on the attending staff from 1890 to 1910; for many years on the associate staff and attending staff of the New Rochelle (N. Y.) Hospital; aged 70; died, Dec. 12, 1938, of coronary thrombosis.

Michael Simon Granelli, Hoboken, N. J.; Jefferson Medical College of Philadelphia, 1906; member of the Medical Society of New Jersey; veteran of the Spanish-American and World wars; school physician; on the staff of St. Mary's Hospital; aged 57; died, Dec. 22, 1938, in the Bayonne (N. J.) Hospital of postoperative pneumonia and carcinoma of the bladder.

William James Adams ⊕ Omaha; Creighton University School of Medicine, Omaha, 1924; instructor in surgery and at various times assistant in anatomy and instructor in medicine at his alma mater; on the staff of the Creighton Memorial St. Joseph Hospital; served during the World War; aged 40; died, Dec. 21, 1938, of hypertension and cerebral hemorrhage.

Frank Joseph Savage ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1928; demonstrator in medicine at his alma mater; on the visiting staffs of the Deaconess Hospital, Grace Hospital and St. Vincent Charity Hospital; aged 38; died, Dec. 10, 1938, of adynamic ileus, partial intestinal obstruction and ulcerative colitis.

Levi Franklin Wagner, Reading, Pa.; University of Vermont College of Medicine, Burlington, 1888; Medico-Chirurgical College of Philadelphia, 1890; member of the Medical Society of the State of Pennsylvania; formerly county coroner and prison physician; aged 75; died, Dec. 14, 1938, in the Reading Hospital of cardiac decompensation.

Byron Coleman Meacher, Portage, Wis.; Rush Medical College, Chicago, 1880; member of the State Medical Society of Wisconsin; fellow of the American College of Surgeons; chief of staff, St. Savior's General Hospital; associate member of the staff, St. Mary's Hospital, Columbus; aged 81; died, Dec. 15, 1938, of Parkinson's disease.

Henry G. Chritzman ⊕ Greencastle, Pa.; Jefferson Medical College of Philadelphia, 1926; on the staffs of the Washington (Pa.) County Hospital, Waynesboro (Pa.) Hospital and the Chambersburg (Pa.) Hospital; member of the school board; aged 37; died, Dec. 10, 1938, in the Jefferson Hospital, Philadelphia, of carcinoma.

Edgar Quinby Bullock, Wilmington, Del.; Hahnemann Medical College and Hospital of Philadelphia, 1905; member of the Medical Society of Delaware; formerly secretary of the Delaware Homeopathic Board of Medical Examiners; on the staff of the Homeopathic Hospital; aged 57; died, February 8, of coronary thrombosis.

Lewis Olds Tayntor ⊕ Conneaut Lake, Pa.; University of Maryland School of Medicine, Baltimore, 1926; formerly connected with the Maryland State Health Department as deputy state health officer of three counties; on the staff of the Meadville (Pa.) City Hospital; aged 53; died, Dec. 28, 1938, of cerebral hemorrhage.

William Reid Thompson, Mackville, Ky.; Kentucky University Medical Department, Louisville, 1905; member of the Kentucky State Medical Association; past president of the Washington County Medical Society; bank president; aged 62; died, Dec. 24, 1938, in the A. D. Price Memorial Hospital, Harrodsburg.

Robert Roy Robinson, Hallsville, Mo.; University of Missouri School of Medicine, Columbia, 1901; member of the Missouri State Medical Association; at one time health officer of Grant County, New Mexico, and Boone County, Mo.; aged 59; died, Dec. 23, 1938, in the Barnes Hospital, St. Louis, of tuberculosis.

Edward Gager Fox, Wethersfield, Conn.; University of the City of New York Medical Department, 1883; member of the Connecticut State Medical Society; health officer for fifty years; formerly physician to the state prison; aged 79; died, Dec. 26, 1938, of cerebral thrombosis, arteriosclerosis and diabetes mellitus.

William Truman Stone, Park Rapids, Minn.; Hahnemann Medical College and Hospital, Chicago, 1882; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; at various times member of the state legislature; aged 83; died, Dec. 26, 1938, of angina pectoris.

Walter C. Ashworth ⊕ Greensboro, N. C.; College of Physicians and Surgeons, Baltimore, 1892; past president of the Guilford County Medical Society; on the staff of the Glenwood Park Sanitarium and formerly owner; aged 70; died, Dec. 16, 1938, in the Wesley Long Hospital of carcinoma of the bladder.

Willard Clark Sanford ⊕ Chicago; Chicago Medical College, 1890; formerly associate professor of surgery, University of Illinois College of Medicine; fellow of the American College of Surgeons; on the staff of St. Elizabeth's Hospital; aged 73; died, Dec. 12, 1938, of coronary thrombosis and hypertension.

Henry M. Ogilbee, Manitou Springs, Colo.; Western Reserve University Medical Department, Cleveland, 1882; member of the Colorado State Medical Society; at various times mayor; aged 82; died, Dec. 6, 1938, in the Beth El Hospital, Colorado Springs, of carcinoma of the urinary bladder.

Maly Emanuel Renner, Lagro, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1881; member of the Indiana State Medical Association; aged 78; died, Dec. 12, 1938, in the Wabash County Hospital, Wabash, of injuries received when struck by an automobile.

Arey Covington Everett ⊕ Rockingham, N. C.; University of Maryland School of Medicine, Baltimore, 1897; secretary and past president of the Richmond County Medical Society; for many years a member of the county board of health; aged 65; died, Dec. 26, 1938, of coronary thrombosis.

Thomas McCullough Maxwell ⊕ Butler, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1903; for many years member of the board of health and school board; formerly on the staff of the Butler County Memorial Hospital; aged 60; died, Dec. 7, 1938, of cerebral hemorrhage.

John Kavanaugh Bullock ⊕ Jackson, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1926; member of the American Academy of Pediatrics; formerly vice president of the Mississippi State Pediatric Society; aged 39; died, Dec. 26, 1938, of cerebral hemorrhage.

David William Van Camp, Plainfield, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; past president of the Cumberland County Medical Society; on the staff of the Carlisle (Pa.) Hospital; aged 67; died, Dec. 30, 1938, of arteriosclerosis and hypertension.

Edward Loring Marr ⊕ Melrose, Mass.; Tufts College Medical School, Boston, 1911; veteran of the Spanish-American War; formerly school physician; on the staff of the Melrose Hospital; aged 61; died, Dec. 17, 1938, in the Middlesex County Sanatorium of pulmonary tuberculosis.

Maggie Letitia McCrea, Sterling, Kan.; Northwestern University Woman's Medical School, Chicago, 1891; member of the Kansas Medical Society; past president of the Rice County Medical Society; aged 74; died, Dec. 19, 1938, in the Sterling Hospital of carcinoma of the stomach.

Joseph Irwin France ⊕ Port Deposit, Md.; College of Physicians and Surgeons, Baltimore, 1903; formerly state senator and United States Senator; at one time secretary of the Medical and Chirurgical Faculty of Maryland; aged 65; died, January 26, of chronic myocarditis.

George McClelland Scott, Waynesburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1891; member of the Medical Society of the State of Pennsylvania; for several years member of the school board; aged 73; died, Dec. 9, 1938, of diabetes mellitus and pancreatitis.

Edward Whitfield Tolley, Grand Rapids, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; member of the Michigan State Medical Society; aged 68; died, Dec. 17, 1938, in St. Mary's Hospital of cerebral hemorrhage.

Marion Whitacre ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1899; formerly clinical instructor in medicine at his alma mater; served during the World War; for many years on the staff of the Christ Hospital; aged 67; died, Dec. 3, 1938, of myocarditis and arteriosclerosis.

Lenus Albert Carl, Newport, Pa.; Baltimore Medical College, 1907; member of the Medical Society of the State of Pennsylvania; formerly secretary of the Perry County Medical Society; aged 60; died, Dec. 1, 1938, in the Harrisburg (Pa.) Hospital of coronary thrombosis.

Charles Edward Holleman, Winston-Salem, N. C.; Jefferson Medical College of Philadelphia, 1932; member of the Medical Society of the State of North Carolina; on the staff of the City Memorial Hospital; aged 34; died, Dec. 20, 1938, of pulmonary tuberculosis.

James J. Cavaney, Milwaukee; Rush Medical College, Chicago, 1879; member of the State Medical Society of Wisconsin; formerly on the staffs of the Milwaukee County Hospital and the Misericordia Hospital; aged 85; died, Dec. 30, 1938, of arteriosclerosis.

Ulysses Irenaeus Tope, Lamartine, Ohio; Ohio Medical University, Columbus, 1895; member and past president of the county board of health and member of the local board of education; aged 68; died, Dec. 15, 1938, following an operation for sarcoma of the sacrum.

Clarence William Weller, Austin, Texas; University of Texas School of Medicine, Galveston, 1913; member of the State Medical Association of Texas; served during the World War; aged 55; died, Dec. 5, 1938, of peritonitis following intestinal obstruction.

John Nicholas Baskett, Hannibal, Mo.; Bellevue Hospital Medical College, New York, 1879; member of the Missouri State Medical Association; on the staff of the Levering Hospital; at one time mayor; aged 85; died, Dec. 29, 1938, of coronary thrombosis.

Grover Cleveland McCormack, Joplin, Mo.; St. Louis College of Physicians and Surgeons, 1910; served during the World War; aged 49; died, Dec. 21, 1938, in the Veterans Administration Facility, Fayetteville, Ark., of pulmonary edema and nephritis.

George W. Pfromm ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1894; formerly assistant professor of therapeutics at his alma mater; consulting physician to the German Protestant Home; aged 69; died, Dec. 4, 1938, of carcinomatosis.

Robert Allen Cavitt, Morrison, Okla.; St. Louis College of Physicians and Surgeons, 1896; member of the Oklahoma State Medical Association; county health officer; formerly member of the state legislature; aged 67; died, Dec. 24, 1938, in a hospital at Pawnee.

Emery Trekell, Wellington, Kan.; Northwestern University Medical School, Chicago, 1910; member of the Kansas Medical Society; county health officer; aged 61; died, Dec. 8, 1938, in the Hatcher Hospital of peptic ulcer, cerebral hemorrhage and uremia.

Frederick Snow Canedy, Wellfleet, Mass.; Boston University School of Medicine, 1891; member of the Massachusetts Medical Society; formerly member of the school committee; aged 70; died, Dec. 12, 1938, of cerebral arteriosclerosis and uremia.

Alpha John Wedel, Hesston, Kan.; University Medical College of Kansas City, Mo., 1910; member of the Kansas Medical Society; aged 56; died, Dec. 25, 1938, in the Bethel Deaconess Hospital, Newton, of lobar pneumonia and cerebral hemorrhage.

William Amos Trivette ⊕ Hamptonville, N. C.; Medical College of Virginia, Richmond, 1916; served during the World War; medical director and superintendent of the Trivette Clinic; aged 50; died, Dec. 20, 1938, of lobar pneumonia and influenza.

Clarence Banjay Wasson, Bellevue, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; member of the Michigan State Medical Society; also a minister; aged 73; died, Dec. 6, 1938, of senility.

George Edwin Lewis, Rockville, Md.; Southern Homeopathic Medical College, Baltimore, 1901; veteran of the Spanish-American and World wars; aged 69; died, Dec. 30, 1938, of arteriosclerosis, hypertension and myocarditis.

John Boyd McKeown, Great Falls, S. C.; Medical College of the State of South Carolina, Charleston, 1909; member of the South Carolina Medical Association; aged 52; died, Dec. 23, 1938, of myocarditis and pulmonary infarction.

Calvin Grant Stookey, Mechanicsville, Iowa; Illinois Medical College, Chicago, 1895; member of the Iowa State Medical Society; aged 73; died, Dec. 12, 1938, in St. Luke's Hospital, Cedar Rapids, of hypostatic pneumonia.

George Seibert Lesher, Eastport, Idaho; University of Pennsylvania Department of Medicine, Philadelphia, 1890; acting assistant surgeon, U. S. Public Health Service; aged 76; died, Dec. 16, 1938, in Spokane, Wash.

Arthur Glenn Davis, Senath, Mo.; St. Louis University School of Medicine, 1928; member of the Missouri State Medical Association; aged 34; died, Nov. 25, 1938, in a hospital at Paragould, Ark., of gastric carcinoma.

Jasper William Coller, Wellsville, N. Y.; Long Island College Hospital, Brooklyn, 1880; past president of the Allegany County Medical Society; for many years health officer; aged 86; died, Dec. 29, 1938, of myocarditis.

William Emerson Tucker, Ipswich, Mass.; Long Island College Hospital, Brooklyn, 1870; formerly member of the school committee; aged 89; died, Dec. 3, 1938, of carcinoma of the stomach and arteriosclerosis.

Lucius Sherman Nichols ⊕ Geneva, Ala.; Medical College of Alabama, Mobile, 1897; secretary of the Geneva County Medical Society; formerly county health officer; aged 66; died Dec. 20, 1938, of pneumonia.

Clarence Mansur Westerman, St. Louis; Barnes Medical College, St. Louis, 1906; served during the World War; aged 52; died, Nov. 23, 1938, in the Veterans Administration Facility, Jefferson Barracks, Mo.

William Eli Morris, Georgiana, Ala.; Medical College of Alabama, Mobile, 1897; member of the Medical Association of the State of Alabama; aged 70; died, Dec. 6, 1938, of uremia.

Phebe Russell Norris ⊕ Washington, D. C.; Columbian University Medical Department, Washington, D. C., 1891; aged 78; died, Dec. 11, 1938, of chronic arthritis and myocarditis.

James C. Harris, Oakfield, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1904; aged 56; died, Dec. 5, 1938, in the Phoebe Putney Memorial Hospital, Albany.

Harry Cordover ⊕ New York; University and Bellevue Hospital Medical College, New York, 1934; on the staff of the Morrisania City Hospital; aged 30; died, Nov. 29, 1938.

David Ulysses Surface, Grand Rapids, Minn.; Sioux City (Iowa) College of Medicine, 1896; aged 70; died, Dec. 2, 1938 of myocarditis, hypertension and arthritis.

Martha V. Thomas, South Bend, Ind.; Hahnemann Medical College and Hospital, Chicago, 1896; aged 83; died in December 1938 of heart disease and hypertension.

Joseph Eli Bird ⊕ New Albany, Ind.; Hospital College of Medicine, Louisville, Ky., 1897; on the staff of St. Edward's Hospital; aged 68; died, Dec. 8, 1938.

James Henry Thomason, Guntersville, Ala.; University of Tennessee Medical Department, Nashville, 1907; aged 56; died, Dec. 4, 1938, of heart disease.

John Edgar Tidwell, Andrews, N. C.; Chattanooga (Tenn.) Medical College, 1903; aged 72; died, Dec. 3, 1938, of cerebral hemorrhage and pernicious anemia.

Fred Harvey Bly, *Red Bluff, Calif.; Northwestern University Medical School, Chicago, 1911;* aged 72; died, Nov. 12, 1938, of endocarditis.

Calvin F. Moranville, Hemingford, Neb. (licensed in Nebraska in 1891); aged 88; died at Bayard in November 1938 of senility.

John Henry George Youell, Aylmer (West), Ont., Canada; University of Toronto Faculty of Medicine, 1892; died, Nov. 28, 1938.

Leslie Roy Aiken, Courtright, Ont., Canada; Western University Faculty of Medicine, London, 1913; aged 51; died, Nov. 16, 1938.

Rosaire Georges Matte, Quebec, Que., Canada; Laval University Faculty of Medicine, Quebec, 1884; aged 77; died Oct. 30, 1938.

Frank William Ramsey, Somerville, Mass. (licensed in Massachusetts in 1901); aged 61; died, Nov. 28, 1938, of heart disease.

George William Stiffler, Denver; Missouri Medical College, St. Louis, 1887; aged 80; died, Nov. 17, 1938, of heart disease.

Andrew Jackson Farley, Irondale, Ala.; Atlanta Medical College, 1890; aged 82; died, Nov. 24, 1938, of cerebral hemorrhage.

Eugene Manigault Baker Jr., Patterson, Ga.; Jefferson Medical College of Philadelphia, 1926; aged 38; died, Nov. 2, 1938.

Garrett White, Chapel Hill, Tenn.; University of Tennessee Medical Department, Nashville, 1889; aged 73; died, Nov. 29, 1938.

Samuel Jacob Morris, Mount Elgin, Ont., Canada; Western University Faculty of Medicine, London, 1900; died, Nov. 5, 1938.

James G. Merrison, Sarnia, Ont., Canada; Faculty of Medicine of Trinity College, Toronto, 1878; died, Nov. 24, 1938.

Herman F. Ratte, Los Angeles; Missouri Medical College, St. Louis, 1886; aged 74; died, Nov. 21, 1938, of myocarditis.

Melville Wright Staples, Pleasant Plains, Ill.; St. Louis Medical College, 1884; aged 88; died, Dec. 8, 1938, of uremia.

Martin G. Fox, Thurmont, Ind.; University of Medicine, Indianapolis, 1898; died, Dec. 1, 1938.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Anogen.—Anogen, Inc., New York. Composition: Essentially furfural. Fraudulently represented as a cure for delayed menstruation.—[*N. J. 27226; October 1937.*]

Bacon's Ferretone Tonic.—Max E. Bacon, trading as Ferretone Co., Wichita, Kan. Composition: Chiefly powdered iron, chalk, phosphates, plant extractives, strychnine and a phenolic compound. "System purifier" and tonic," etc. Fraudulent therapeutic claims.—[*N. J. 27135; August 1937.*]

Big-Chief Herbs.—Spors Co., Le Center, Minn. Composition: Essentially plant material including lavender flowers and oil of mustard. For headaches, sinus, catarrh, hay fever and asthma. Fraudulent therapeutic claims.—[*N. J. 27538; January 1938.*]

Cadum Ointment.—Omega Chemical Co., New York. Composition: Essentially zinc oxide (20.4 per cent), sulfur (4.6 per cent), salicylic acid and oil of cade, in a petrolatum and wax base. Proportions of zinc oxide and sulfur falsely stated on label. Fraudulently represented to cure skin diseases, hemorrhoids, etc.—[*N. J. 27364; December 1937.*]

Cal-O-San Stomach Tablets.—G. Brewerton, Fort Browning, Mont. Composition: In each tablet, bismuth subcarbonate (10½ grains), chalk (6 grains), baking soda (10½ grains), starch and peppermint oil. For stomach ulcers, etc. Fraudulent therapeutic claims.—[*N. J. 27142; August 1937.*]

Corley's (Dr.) Cor-Lax.—Buren L. Corley, trading as Dr. Corley's Products, San Francisco. Composition: Essentially plant material including senna and peppermint leaves, cascara bark and fennel seed. Fraudulently represented as a cure for excess acid, upset stomach, congested liver, cancer, tuberculosis, diabetes, kidney and heart trouble, etc.—[*N. J. 27267; October 1937.*]

Corley's (Dr.) Health Broth.—Buren L. Corley, trading as Dr. Corley's Products, San Francisco. Composition: Essentially plant material, including alfalfa leaf and stem, okra, tomato, red pepper, celery seed, onion, potato starch, plant tissue resembling Irish moss, starchy material, and small amounts of stem, leaf and root tissues lacking in diagnostic tissue elements. Fraudulently represented as a cure for mineral and vitamin deficiency diseases, such as stomach gas and ulcers, all digestive upsets, skin ailments, depleted blood, all forms of rheumatism, etc.—[*N. J. 27267; October 1937.*]

Davis (G. W.) Inflammatory Extirpator.—Charles L. Isherwood & Sons, Fall River, Mass. Composition: Essentially alcohol (69.2 per cent), red pepper, a gum, water, and volatile oils including turpentine and camphor. Fraudulently represented as a remedy for external and internal pain, coughs, asthma, croup, headache, urinary diseases, rheumatism, etc.—[*N. J. 27146; August 1937.*]

Dunlap's Antiseptic Liniment.—Morna Wright Medicine Co., and Dunlap Medicine Co., Memphis. Composition: Essentially alcohol (78 per cent), water, and small amounts of chloroform, extracts of plant drugs, ammonia, and volatile oils including sassafras and eucalyptol. For rheumatism, toothache, headache, diarrhea, colic, etc. Fraudulent therapeutic claims.—[*N. J. 27534; January 1938.*]

Elco-Rub.—Erie Laboratories, Cleveland. Composition: Essentially petrolatum, oils of eucalyptus, wintergreen and turpentine, with camphor, menthol and guaiacol. For sore throat, croup, whooping cough, rheumatism, catarrh, etc. Fraudulent therapeutic claims.—[*N. J. 27360; December 1937.*]

Essential Food Minerals.—H. C. Roberts Co., Sioux City, Iowa. Composition: "Essential Food Minerals" was chiefly milk sugar (97.1 per cent), with traces of potassium, sodium, calcium, magnesium, iron, manganese, copper and silicon compounds, chlorides, phosphates and sulfates; "Special Gland Food Essential Food Minerals" was chiefly milk sugar (95.6 per cent), with traces of sodium, potassium, calcium, magnesium, iron, manganese, copper and silicon compounds, chlorides, phosphates, sulfates and iodides; "Special Iodine Containing Essential Food Minerals" was chiefly milk sugar (98.2 per cent), with traces of sodium, potassium, calcium, magnesium, iron, manganese, copper and silicon compounds, chlorides, sulfates, phosphates and iodides. Fraudulently represented for "tonic" and "building-up" purposes and as remedies for numerous ailments.—[*N. J. 27258; October 1937.*]

Ferretone Eye Lotion.—Max E. Bacon, trading as Ferretone Co., Wichita, Kan. Composition: Boric acid, menthol and a yellow color. Fraudulently represented to cure all ordinary eye affections, excessive secretion of tears, fatigued vision, ulcerated eyelids, etc., and to prevent "serious and lamentable diseases and loss of sight."—[*N. J. 27135; August 1937.*]

Foot Pal.—Spors Co., Le Center, Minn. Composition: Essentially small amounts of sodium salicylate, glycerin and pine needle oil in water, colored with a green dye. Fraudulently represented as an antiseptic and a cure for blisters resulting from nail wounds.—[*N. J. 27538; January 1938.*]

Geba.—Vitamin Products Research Foundation, Inc., Chicago. Composition: Protein, starch, sugars and compounds of calcium and magnesium, phosphates and carbonates, with approximately 2 U. S. P. units of vitamin A per tablet. Adulterated because not up to the standard of vitamin A represented for it; misbranded because fraudulently indicated to promote health, a vigorous, robust mind and body, disease resistance, sexual impotence, etc., and to combat infections, prevent anemia and cure irritability, listlessness and beriberi.—[*N. J. 27353; December 1937.*]

Grandma's Medicinal Herbs.—Park Laboratory Co., Inc., San Antonio, Texas. Composition: Essentially senna and small amounts of couch grass, American saffron, caraway seed, anise seed, licorice root, sassafras bark, lavender flowers, bearberry leaves and cinnamon bark. Fraudulent therapeutic claims for its alleged "cleansing" properties.—[*N. J. 27236; October 1937.*]

Hain Vegetable Accessory Reducing Food.—Hain Pure Food Co., Los Angeles. Composition: An appreciable amount of seaweed material, plus some nondescript vegetable tissues. Fraudulently represented as a food for the underweight and overweight, and as supplying dietary minerals.—[*N. J. 27527; January 1938.*]

Harosma.—Erie Laboratories, Cleveland. Composition: Essentially phenacetin (2.5 grains), aspirin (2.7 grains) and caffeine (1/7 grain), in each capsule. Adulterated and misbranded because each capsule did not contain 4 grains of phenacetin, as labeled; misbranded, further, because fraudulently represented as a cure for rose fever, rhinitis, la grippe, weeping eyes, etc.—[*N. J. 27234; October 1937.*]

He-She Antiseptic Vaginal Suppositories.—Helm Co., Benton Harbor, Mich. Composition: Essentially coco butter and boric acid, with small amounts of salicylic acid and quinine. Fraudulently represented as a preventive of leucorrhea and a germicide, and as being prescribed by eminent physicians.—[*N. J. 27275; October 1937.*]

Hygem.—Bloomfield Laboratories, Bloomfield, N. J. Composition: Viable micro-organisms to the amount of not less than 7 million per tablespoonful; no acidophilus bacilli found, though the label described the stuff as "The Mineral Oil Emulsion With Acidophilus." This misrepresentation constituted misbranding, as did the statement "Contains no Drugs nor Cathartics." Other claims were declared fraudulent.—[*N. J. 27388; December 1937.*]

Ice-Mint.—United Sales and Mfg. Co., Binghamton, N. Y. Composition: Essentially water, borax, camphor and menthol, in an ointment base. For nervous headache, sore muscles, corns and calluses, burns, "piles," etc. Fraudulent therapeutic claims.—[*N. J. 27237; October 1937.*]

Kayan.—Allied Laboratories, New York. Composition: Essentially phenolphthalein (about 1.2 grains per teaspoonful); a gum, sugar and starch. Fraudulently represented as a remedy for constipation, intestinal fermentation, toxemia, autointoxication, etc.—[*N. J. 27139; August 1937.*]

Kelement.—Lee Kelpodine Co., Inc., New York. Composition: Tablets consisting simply of kelp. Fraudulently represented as containing medicinal agents which, used as a food accessory, would be beneficial in mineral-salt deficiencies, soft and decayed teeth, pyorrhea, anemia, goiter, nervousness, insomnia, diabetes, frigidity, sterility, etc.—[*N. J. 27127; August 1937.*]

Kelpodine.—Lee Kelpodine Co., Inc., New York. Composition: Tablets consisting simply of kelp. For anemia, goiter, rickets, obesity, asthma, arthritis, dyspepsia, sterility, etc. Fraudulent therapeutic claims.—[*N. J. 27129; August 1937.*]

Kopp's.—C. Robert Kopp, Inc., Hellam and York, Pa. Composition: Morphine sulfate (1/6 grain per fluidounce), flavoring oils including anise oil, with alcohol, sugar and water. Fraudulently represented as a safe and appropriate remedy for babies and infants, whereas it contained morphine, a poison.—[*N. J. 27264; October 1937.*]

Kroup Monia Cough Syrup.—W. D. Taylor & Co., Bessemer, Ala. Composition: Essentially sugar, water, ammonium chloride, glycerin, alcohol, chloroform (1.3 minims per fluidounce), menthol and extracts of plant materials including pine. Fraudulently represented as a safe and effective treatment for croup, whooping cough, etc.—[*N. J. 27384; December 1937.*]

Lawrence's Liniment.—Crain's Corner Drug Store, Longview, Texas. Composition: Essentially glycerin, carbolic acid, iodine, alcohol (2.8 per cent by volume) and chloroform (27 minims per fluidounce). Fraudulently represented as a cure for croup, soreness of lungs, etc.—[*N. J. 27371; December 1937.*]

Lifsey's Vim Herb.—A. P. Durham, Anderson, S. C. Composition: Plant extractives and one or more emodin-bearing drugs. For stomach, kidney, liver and blood disorders, etc. Fraudulent therapeutic claims.—[*N. J. 27149; August 1937.*]

Menard's French Croup Suet.—Menard & Watson, Macon, Ga. Composition: Essentially creosote and volatile oils including camphor, incorporated in a fat. Fraudulent therapeutic claims.—[*N. J. 27372; December 1937.*]

Mentho-Korchlet.—*Rieser Co., Inc., Shamokin, Pa.* Composition: Essentially tissue paper, impregnated with menthol and other perfumes. Fraudulently represented as a remedy for sinus trouble, hay fever, etc.—[*N. J. 27272; October 1937.*]

Miller's Antiseptic Oil.—Herb Products Medicine Co., and Herb Juice Medicine Co., Jackson, Tenn. Composition: Essentially kerosene, with small amounts of red pepper and volatile oils including those of turpentine, wintergreen and sassafras. Fraudulently represented to contain no injurious substances and to be a remedy for muscular rheumatism, burns, scalds, diarrhea, cramps, etc.—[*N. J. 27249; October 1937.*]

Minnehaha Indian Herbs.—Spors Co., Le Center, Minn. Composition: Essentially plant material including senna leaves, gentian root, bearberry, triticum, and unidentified plant substances. Fraudulently represented to cure constipation and its results, such as rheumatism, kidney trouble, stomach disorders, etc.—[*N. J. 27538; January 1938.*]

Munyon's Tona Spaf.—*Munyon Remedy Co., Scranton, Pa., and Sunshine Co., New York.* Composition: Essentially an iron and phosphorus compound, with a small amount of an arsenic compound, plus alcohol, water and flavoring material. Fraudulently labeled as a blood purifier and remedy for la grippe, anemia, insomnia, diabetes, etc.—[*N. J. 27256; October 1937.*]

Naco Nature's Aid.—Naco Co., Jackson, Miss. Composition: Essentially iron sulfate and water, with small amounts of aluminum, calcium, magnesium, manganese, sodium, potassium and phosphorus compounds. Not a germicide, as claimed. Fraudulently represented as a remedy for sores, burns, rheumatism, kidney pus, dysentery, etc.—[*N. J. 27143; August 1937.*]

Nash's Carbolic Salve.—Nash Bros. Drug Co., Jonesboro, Ark. Composition: Essentially petrolatum, with small amounts of carbolic acid, camphor, rosin and boric acid. For salt rheum, tetter, eczema, felons, etc. Not antiseptic, as represented. Fraudulent therapeutic claims.—[*N. J. 27535; January 1938.*]

Nash's Pain-Go.—Nash Bros. Drug Co., Jonesboro, Ark. Composition: Essentially kerosene, with small amounts of volatile oils such as turpentine and sassafras. Fraudulently represented as a "snake oil" and an "antiseptic."—[*N. J. 27535; January 1938.*]

Ourine Nasal Balm and Ourine Application for the Ears.—Aurine Co., Chicago. Composition: "Nasal Balm," essentially mineral oil with small amounts of menthol, wintergreen, and green color; "Ourine Application for the Ears," essentially glycerin, boric acid, extracts of plant drugs and volatile oils, including lavender. Fraudulently represented as remedies for nose and ear troubles.—[*N. J. 27400; December 1937.*]

Picot Compound Tablets.—Picot Laboratories, Inc., Wilmington, Del. Composition: Essentially sodium salicylate, sodium benzoate, potassium nitrate, magnesium carbonate, bearberry and oil of juniper. Fraudulently represented as a cure for rheumatism, an aid to stomach and kidneys, and a blood purifier.—[*N. J. 27375; December 1937.*]

Picot Grape Flavored Salt.—*Picot Laboratories, Inc., Wilmington, Del.* Composition: Essentially baking soda, cream of tartar and tartaric acid, with small amounts of sugar and saccharin. No grape-like taste or odor detected. Fraudulently represented as a remedy for rheumatism.—[*N. J. 27375; December 1937.*]

Ra-Ed-O Pile Suppositories.—Helm Co., Benton Harbor, Mich. Composition: Essentially coco butter, with small amounts of quinine, salicylates, iron compounds and sulfates. "For all forms of piles—bleeding, itching and protruding . . ." Fraudulent therapeutic claims.—[*N. J. 27275; October 1937.*]

Radiumized Health Pad.—Radiumized Applicator Co., Inc. (address not given). Composition: 53 millimicrograms of radium per gram of ore, or 1,695 millimicrograms of radium per pad. Fraudulently represented to insure health and to cure kidney or bladder trouble, constipation, high blood pressure, goiter, skin diseases, etc.—[*N. J. 27259; October 1937.*]

Radiumized Water Revitalizer.—Radiumized Applicator Co., Inc. (address not given). Composition: Radium emanation (radon) in the proportion of 165 millimicrocuries of radon per U. S. quart. Fraudulently represented to "revitalize," to prevent illness, and to be a remedy and cure for chronic ailments, such as rheumatism, arthritis and gout.—[*N. J. 27259; October 1937.*]

R-P 60 Bladder and Gland Remedy.—Helm Co., Benton Harbor, Mich. Composition: Essentially water and extracts of plant drugs (including a laxative), with a small amount of salicylate. Misbranded because fraudulently represented for disorders of the kidney, bladder, rectum and spinal cord, among other things.—[*N. J. 27275; October 1937.*]

Rozel Douche Powder.—Rozel Laboratories, Chicago. Composition: Boric acid, common salt, ammonium alum, and small amounts of carbolic acid and menthol. Fraudulently represented as a cure for inflammations, irritations, leucorrhea, "feminine hygiene," etc.—[*N. J. 27363; December 1937.*]

Rozel Effervescent Cones.—Rozel Laboratories, Chicago. Composition: Essentially tartaric acid, baking soda, talc, starch and a small amount of a chlorine-liberating compound. Not a germicide for vaginal use, as represented. Fraudulent therapeutic claims.—[*N. J. 27547; January 1938.*]

Rx 333.—Eric Laboratories, Cleveland. Composition: Essentially aspirin and sodium salicylate. For the pains of rheumatism, neuralgia, gout, arthritis, lumbago, etc. Fraudulent therapeutic claims.—[*N. J. 27374; December 1937.*]

Rx 333 for Females.—Foundation Laboratories, Inc., Chicago. Composition: Essentially water, alcohol (34 per cent) and small amounts of phosphates, magnesium compounds, protein and perfume. Fraudulently labeled as effective for many female disorders, including certain types of sterility.—[*N. J. 27385; December 1937.*]

Rx 444 for Males.—*Foundation Laboratories, Inc., Chicago.* Composition: Water, alcohol (40 per cent) and small amounts of phosphates, magnesium compounds, protein and perfume. Fraudulently represented as a remedy for prostate and bladder troubles, backache, rheumatism, impotence, etc.—[*N. J. 27385; December 1937.*]

Sasa Scalp and Skin Aid.—Sasa Distributors, Portland, Ore. Composition: Essentially water and alcohol, with small amounts of borax, arsenic, caramel and oil of cinnamon. For dandruff, falling hair, eczema, etc. Fraudulent therapeutic claims.—[*N. J. 27366; December 1937.*]

Scheidemann Remedy Tea.—Scheidemann Remedy Co., Inc., Milwaukee. Composition: Essentially ground wood, twigs and needles, with juniper berries. Fraudulently represented as a remedy for diabetes, kidney disorders, etc.—[*N. J. 27235; October 1937.*]

Six-ine Pills.—Kells Co., Inc., Newburgh, N. Y. Composition: Essentially an iron compound, quinine, strychnine, starch and chalk. Fraudulently represented as a remedy for nervous exhaustion and depression.—[*N. J. 27532; January 1938.*]

Stark's Headache Powders.—Stark's & Co., Midway, Ky., McKesson-Peter-Neat Co., Louisville, Ky., and Kells Co., Newburgh, N. Y. Composition: Essentially acetanilid (averaging 6.75 grains per powder), caffeine and baking soda. Fraudulent therapeutic claims.—[*N. J. 27354; December 1937.*]

Tabletas Marca Vida Para Los Ninos.—*Mexican Medicine Co., Los Angeles.* Composition: Essentially compounds of bismuth, calcium, sodium, potassium, carbonates, nitrates, starch, and extracts of plant drugs including emodin. Fraudulently represented as a cure for numerous disorders in infants.—[*N. J. 27134; August 1937.*]

Urisептin.—Gardner Laboratories, Chicago. Composition: Methenamine, water, glycerin, and extracts of plant material including corn silk, with small amounts of alcohol and salts of sodium, potassium and lithium. Fraudulently represented as a cure for Bright's disease, cystitis, rheumatism, gout, pneumonia, gonorrhea, etc.—[*N. J. 27367; December 1937.*]

Vegetrates.—Health Foundation of California, Los Angeles. Composition: "B. F. 1," essentially vegetable substances including rice bran, cinnamon, cranberry, kelp and leafy vegetables, as well as senna leaves and rhubarb; "B. F. 1" (in tablet form), also contained lime; "Formula H. F. C. No. A-45" (for arthritis), "D-44" (for diabetes), "A-417" (for hay fever and asthma), and "H-410" (for high blood pressure) were reported to consist essentially of unidentified root, stem and leaf material. All were declared misbranded because fraudulently represented to be "health builders" and to cure various disorders.—[*N. J. 27263; October 1937.*]

Vi-Go-Ra Olive Oil Hair Tonic.—Vi-Go-Ra Co., Providence, R. I. Composition: Essentially alcohol (about 77 per cent by volume), castor oil, a sulfonated oil, water and a coloring material. Misbranded because not more than a trace of olive oil was present, if any, and quantity or proportion of alcohol present was not declared on the label; misbranded, further, because of fraudulent claims that it would stop itching scalp instantly, check falling hair, and relieve eczema.—[*N. J. 27399; December 1937.*]

Vita-Mil.—Vita-Mil Co., Charleston, W. Va. Composition: Essentially epsom salt (about 20 per cent) and extracts of plant drugs, including a laxative, with small amounts of sodium benzoate, sugars, saccharin, caramel, flavoring material and water. Adulterated because not a herbal compound, as represented, but a mixture consisting largely of a mineral drug, epsom salt. For stomach and liver troubles, etc. Fraudulent therapeutic claims.—[*N. J. 27380; December 1937.*]

Wah-Poo-Sah Kee-Kee-Kee.—MacDonald Medicine Co., Detroit. Composition: Essentially water and alcohol, with small quantities of plant drugs, including a laxative. Fraudulently represented as "activating the muscle of the bowels" and as containing "no drugs of any kind."—[*N. J. 27248; October 1937.*]

Wil-Du Rheumatism and Gout Medicine.—Wil-Du Medicine Co., Woodbury, N. J. Composition: Essentially alcohol (67 per cent by volume), water, and extracts of plant drugs including senna. Fraudulent therapeutic claims.—[*N. J. 27398; December 1937.*]

World's Wonder System Builder.—World's Wonder Medicine Co., Inc., Detroit. Composition: Essentially epsom salt, extracts of plant drugs including a laxative, with sugar and water. Misbranded because represented to contain chiefly horehound, prickly ash, red clover, red puccoon, black root and pokeroot. Fraudulently represented as a cure for indigestion, scrofula, skin and blood diseases, kidney trouble, chronic rheumatism, etc.—[*N. J. 27540; January 1938.*]

Zonalife.—Zonalife Distributors, St. Louis. Composition: Essentially epsom salt and water, with small amounts of iron and sodium compounds, salicylic acid, wintergreen and saccharin. Fraudulently represented as a cure for headaches, sluggish kidneys, rheumatism and high blood pressure.—[*N. J. 27245; October 1937.*]

Correspondence

THE STATUS OF RETICULOGEN

To the Editor:—The communication from Dr. William P. Murphy, which appeared on page 169 of the January 14 issue of THE JOURNAL, in which he discussed the value of reticulogen, calls for a reply and word of explanation from the U. S. P. Anti-Anemia Preparations Advisory Board.

According to Dr. Murphy, Eli Lilly & Co. has stated in certain advertising literature that "Reticulogen contains 20 units of anti-pernicious anemia principle per cc." Eli Lilly & Co. have not, however, submitted Reticulogen for consideration by the U. S. P. Anti-Anemia Preparations Advisory Board. Consequently the board has made no statement of the potency of this product in terms of U. S. P. units. Moreover, on page 629 of the August 1938 issue of the *Journal of the American Pharmaceutical Association* the board stated that "it will not for the present assign to any preparations of injectable liver extract a strength greater than fifteen units per cubic centimeter." Finally, the U. S. P. advisory board has not published any standards for hemopoietic responses to which Eli Lilly & Co. could refer. Indeed, data concerning hemopoietic responses are only a part of the information which is considered by the board in the assignment of unitage to satisfactory products. Thus it should be entirely clear that the claim of Eli Lilly & Co. does not refer to U. S. P. units but can relate only to units of an entirely unofficial character.

The U. S. P. advisory board is the only agency for assigning U. S. P. units to liver and stomach preparations. Therefore, if any manufacturer labels a product in terms of units other than U. S. P. units, they are units devised merely by that manufacturing house and must not be identified with U. S. P. units. It is most regrettable that the use of such unofficial units should exist and thus lead to confusion. If one manufacturer determines his own units, so may all, and thus the work of the advisory board in securing uniformity of labeling would go for naught.

The board, therefore, took the matter up with the manufacturers of Reticulogen, pointing out the difficult situation which had arisen, and asked them whether they would not change their labels and advertising literature by withdrawing the term "unit" and in this way help to clarify the situation. It is pleasant to report that Mr. Eli Lilly, president of Eli Lilly & Co., has informed the board that in the future on its labels and in its advertising literature it will describe the potency of its product in another way than by the term "unit."

A final word of explanation concerning the definition of a U. S. P. unit should be made. It will be recalled that the first publication of this board, made Feb. 14, 1938, defined the term "U. S. P. unit" as "that amount of material which, when given daily to patients with pernicious anemia, has produced a satisfactory hematopoietic response." It is perhaps desirable to point out that such a definition of a U. S. P. unit does not imply that it represents the minimal amount of effective material which might result in a satisfactory response but merely that particular amount of material which has in fact produced such a response.

Thus if a manufacturer submits at a later time data indicating that a smaller amount of material than that originally tested will give a response satisfactory to the board, a greater unitage for a given amount of the same preparation will be officially assigned. It should therefore be understood that U. S. P. units are not necessarily interchangeable from one product to another. Nevertheless, from the point of view of the patient and the physician it is of far greater practical importance that the official U. S. P. unit should indicate that amount of material which will assuredly possess the potency just defined.

UNITED STATES PHARMACOPEIAL ANTI-ANEMIA
PREPARATIONS ADVISORY BOARD.
By C. W. EDMUNDS, Chairman.

MAGNESIUM SULFATE IN PAROXYSMAL TACHYCARDIA

To the Editor:—In THE JOURNAL, Dec. 17, 1938, page 2275, is a discussion by William Dressler on the use of magnesium sulfate in paroxysmal tachycardia. In *Klinische Wochenschrift* (**14**:1429 [Oct. 5] 1935) was reprinted my research: Ueber die Magnesiumwirkung auf das Herz (The Influence of Magnesium Sulfate on the Heart). This paper was abstracted in THE JOURNAL, Nov. 23, 1935, page 1727. I was the first to report the use of magnesium sulfate in paroxysmal tachycardias and ventricular fibrillation. About the same time was published an experimental study on the effect of magnesium on tachycardia produced by barium and strophanthin (Rothberger, C. J., and Zwillinger, L.: Ueber die Wirkung von Magnesium auf die Strophantin- und die Barium-tachycardie, *Ach. f. exper. Path. u. Pharmakol.* **181**:301, 1936). Dr. Dressler learned this use of magnesium sulfate from me in Vienna. Therefore I was astonished to read that he did not name me as the author of this work.

L. ZWILLINGER, M.D., Prostějov, Czechoslovakia.

CERTIFICATION OF STAINING SOLUTIONS

To the Editor:—In a recent note in THE JOURNAL (Sept. 24, 1938, p. 1239), attention was called to the work that is being done by the Commission on Standardization of Biological Stains, and the question was raised as to whether it would not be possible for this organization to be of more assistance to physicians if its duties were broadened so as to include the approval of satisfactory staining solutions as well as stains in the solid form. In this earlier note the difficulties of doing this were discussed, and the article ended with a query as to who are the chief purchasers of stains in solution form and as to which particular staining solutions give the most trouble at present.

Considerable comment concerning this article has been received, and it is felt that, to a certain extent, the questions asked have been answered. It has been concluded from the comments received that physicians are, as was suspected, the chief purchasers of staining solutions. It also appears that the biggest demand is for the blood stains and that solutions of this type apparently give the most trouble if purchased from an unreliable source. The physician or technician who has to make a blood stain himself but is not equipped to make up the necessary solution or for some other reason finds it inconvenient to do so usually cannot take time to write to some supply house in a distant city in order to obtain the solution already prepared. There is no question but that it would be of assistance to such a physician if some local dispensary of known reliability was available to him from which he could purchase the staining solution he needed.

Since publication of the previous article, the commission has had its attention called to a group of technicians here, a private laboratory there and some individual somewhere else who are disinterestedly trying to supply local physicians in a semi-commercial way with reliable staining solutions. It is felt that there must be other organizations, such as clinical laboratories, or persons endeavoring to do the same sort of thing in other places. Undoubtedly the Stain Commission could be of assistance to any one who is sincerely trying to do this. It could help by seeing that the best ingredients, proper formulas and approved methods of preparation are employed, by arranging to test the products without prohibitive expense to those who prepare the solutions and finally by adopting some plan to assure the purchaser of the reliability of the stains thus prepared.

This note is published in the hope that any persons or organizations who are trying to supply superior staining solutions to physicians and who would welcome the cooperation

of the Stain Commission will get in touch with the chairman at the address given. It is felt that some practical plan can be worked out; but before putting any such plan into operation, we must have a little clearer idea than at present how widespread will be the cooperation we can have in the project. Physicians reading this article can be of assistance in calling it to the attention of some one in their locality who they think might be fitted to cooperate with them and with us in such an undertaking.

H. J. Conn, Ph.D., Geneva, N. Y.
Chairman, Biological Stain Commission.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

CRITERIA OF CURE IN NEUROSYPHILIS

To the Editor:—What tests and observations are of the greatest importance in the examination of the spinal fluid to determine whether a cure of syphilis has been effected? What tests in a neurologic examination are most important in determining whether a patient has been cured?

M.D., Kentucky.

Answer.—This question cannot be answered without a brief discussion of the criteria of "cure" in syphilis. The word "cure" may be applied in three different senses: (*a*) biologic, (*b*) serologic and (*c*) symptomatic. Biologic cure implies that the last remaining spirochete has been eradicated from the patient's body, that he is rendered susceptible to reinfection with syphilis and usually that he is simultaneously "cured" from serologic and symptomatic standpoints. So far as is now known, biologic "cure" is attainable only when treatment is begun in the early stages of syphilitic infection, probably within the first six months. It cannot, so far as is known, be accomplished in patients with late syphilis.

Serologic "cure" implies that all serologic reactions of the blood and spinal fluid are rendered negative and remain so. This type of "cure" is not necessarily synonymous with biologic cure, since serologic "cure" is attainable in some instances of late as well as of early syphilis; nor is it synonymous with symptomatic "cure," since clinical progression or relapse may take place in the face of persistently negative serologic reactions.

Symptomatic "cure" implies that the patient is relieved of symptoms or lesions caused by syphilis, that he is restored to normal health, is maintained in normal health for the duration of his lifetime and is rendered noninfectious for others. Symptomatic "cure" is synonymous with neither biologic nor serologic "cure," since symptomatic "cure" may be attained both in early and in late syphilis without complete eradication of the infection and with positive serologic reactions of the blood or spinal fluid, or both, persisting. For example, symptomatic "cure" is even attainable in dementia paralytica, though in such patients both foci of organisms, positive serologic reactions of the blood and spinal fluid and neurologic abnormalities may persist.

Strictly speaking, therefore, neither the examination of the spinal fluid nor a neurologic examination can be used as a definite criterion of "cure" of syphilis, either biologic, serologic or symptomatic. It is, however, true that in early syphilis examination of the spinal fluid should be employed as a routine as (*a*) a determinant of the type and amount of desirable treatment and (*b*) a criterion for the complete cessation of treatment. For the former purpose, examination of the spinal fluid should be performed as a routine at about the sixth month after the institution of treatment. If at this time the spinal fluid is normal, treatment may proceed by standardized routine methods. If, on the other hand, the spinal fluid is abnormal, alterations in the treatment system are frequently necessary to provide for the contingency of asymptomatic neurosyphilis. For the latter purpose, i. e. as a determinant of "cure," examination of the spinal fluid should be repeated in all patients with early syphilis at the end of a post-treatment year of probation and regardless of whether the original spinal fluid was normal or abnormal. If at the time of this last examination of the spinal fluid abnormalities are found, treatment should be resumed.

In late syphilis, i. e. of more than two years' duration, a whether or not the patient has symptoms or physical signs poi ing to involvement of the nervous system, the spinal fluid sho be examined before any treatment is given or as early as p sible in its course. If the original examination of the spi fluid of a patient with late syphilis is negative it need not repeated, since in persons in whom immunity has been esta lished a normal spinal fluid is a practical guaranty against t subsequent development of syphilis of the central nervous syste If, however, in late syphilis the spinal fluid is abnormal at t original examination, reexamination of the fluid during a after treatment is essential in order to estimate the effectivene of treatment, to provide for alterations in its type if necessa and to gage the optimal amount of treatment desirable.

The tests obligatory in the examination of spinal fluid at a stage of syphilitic infection are (*a*) cell count, which must performed within one hour after the fluid has been withdraw (*b*) protein estimation, preferably by a quantitative technic, (Wassermann test on graduated amounts of fluid ranging fro 0.1 to 1 cc. (flocculation tests on spinal fluid are less satisfacto than complement fixation tests) and (*d*) a colloidal gold, mast or benzoin test.

Like examination of the spinal fluid, results of a neurologi examination, whether negative or positive, can be used as criterion of "cure" in syphilis only in the light of the discussio of "cure" briefly given. In patients with early syphilis it ma be taken for granted that at the start of treatment neurologi abnormalities are absent (excepting the rare instance of acut syphilitic meningitis or the contraction of syphilitic infection b a patient with some other neurologic disease). If the patie with early syphilis is normal from the neurologic standpoint, h should remain so not only during the period of treatment an the post-treatment year of observation but also during yearl periodic recheck examinations for the duration of his life.

In patients with late syphilis, however, and even in those wh have neurologic abnormalities present at the start of treatment symptomatic cure may often be attained. In this case the impor tant feature of recheck examinations from the neurologic stand point is not the disappearance of abnormalities which were originally present but instead the absence of progression in these abnormalities or the nondevelopment of fresh ones.

It is impossible in the brief confines of such a reply as this to outline the steps of complete neurologic examination. Assuming the absence of gross neurologic abnormalities, however, the most important features of recheck examination of treated syphilitic patients are the state of the pupillary reactions both to light and in accommodation; examination of the optic fundus as to the appearance of the optic disks and also a test of visual acuity and at least gross tests of the visual fields; the presence or absence of conduction deafness; tests of the deep and superficial reflexes, especially knee and ankle jerks; tests of deep pain sense by squeezing the achilles tendon and the gonads; tests for vibratory sense in the lower extremities, particularly over the malleoli and tibias; tests for ataxia, including not only such gross tests as the Romberg, the knee-heel, the finger-nose and the finger-finger, but also more delicate tests such as position sense in the great toes, and sensory examination for abnormalities of light touch and pain, particularly in zonelike distribution over the thorax or in patchy distribution over the fronts of the shins.

DIAPER RASH

To the Editor:—Would you please outline a proper course of dietary and local management for a severe case of ammoniacal dermatitis.

M.D., Wisconsin.

Answer.—Ammoniacal dermatitis is an erythematous dermatitis occurring in the napkin area of infants. It is an intertrigo caused by friction of the diaper or by uncleanliness. Ammonia is formed in the wet diaper in situ by the growth of a saprophytic bacillus which splits the urinary urea into ammonia. This bacillus, according to Cooke (The Etiology and Treatment of Ammonia Dermatitis of the Gluteal Region of Infants, *Am. J. Dis. Child.* **22**:480 [Nov.] 1921), is derived from the intestinal contents and infests the diaper as a result of soiling by feces. The best treatment is prophylactic. The diaper should be washed with scrupulous cleanliness, rinsed thoroughly several times in clear water and then put through a final rinsing of boric acid solution. The use of soap and water on the affected parts should be avoided and the skin cleansed with olive oil or liquid petrolatum. A soothing lotion such as zinc oxide 12 Gm., talcum 8 Gm., glycerin 6 cc., sodium borate 6 Gm. and solution of calcium hydroxide to make 240 cc. may be used, or the following ointment: purified tar 3 Gm., zinc oxide 8 Gm., starch 8 Gm. and simple ointment to make 30 Gm.

DOG BITES AND RABIES

To the Editor:—In connection with the prevention of human rabies, would you kindly discuss the following questions: Is it a fact that the patient's skin wound must be of subcutaneous depth before the Pasteur treatment is indicated (assuming that cauterization has previously been performed)? If no bite has been incurred but the skin has been in contact with the saliva of a rabid animal, is treatment indicated? Do the presence of small superficial breaks in the skin, such as scratches, partially healed cuts and pimples indicate treatment if the patient has had contact with a rabid animal? JOHN M. COLLINS, M.D., Seattle.

ANSWER.—There are many thoughtful persons who deplore the cauterization treatment of dog bites or any other open wounds. They believe that such methods are only a repetition of the hot oil treatment of wounds, which was considered proper treatment in the days of Ambroise Paré but which thinking persons have abandoned just as did Paré.

Some believe that if the patient is seen immediately after a wound or bite has been sustained the most effective method of treatment is careful, patient and prolonged cleansing of the wound with soap and water and subsequent irrigation of the wound with warm salt solution. The depth of the wound would have no influence in modifying this treatment except that an irregular wound should be opened or enlarged sufficiently to make sure that every portion of it is reached by the soap and water and salt solution. When the wound resulting from a bite is treated immediately and carefully in this fashion the administration of antirabies serum is not advocated in all instances. On the other hand, if the wound is not seen promptly after the injury has been sustained and so there has been opportunity for the virus to enter the deeper tissues, it should still be cleansed as carefully and thoroughly as possible and this cleansing should be followed with the Pasteur treatment.

ISOLATION OF TUBERCULOUS PATIENTS IN GENERAL HOSPITALS

To the Editor:—The county medical society requested a tuberculosis survey. This survey was recently published and under Institutional Care is found the statement: "The county needs additional beds for the tuberculous. The attitude of the local hospitals is commendable in admitting and caring for the tuberculous for limited periods of time, but the necessary prolonged period of bed rest is not possible and thus far in *these hospitals the isolation of the tuberculous has not been accomplished.*" The last clause has caused considerable discussion, so I am coming to you for an answer to the following question: What precautionary measures should be employed when tuberculous patients are confined to a general ward in a hospital? EXECUTIVE SECRETARY, COUNTY SOCIETY.

ANSWER.—There is excellent support for opening a general hospital to tuberculous patients. As early as 1895 Dr. Lawrence Flick of Philadelphia made a provision for such use of general hospitals. In 1908 the International Congress on Tuberculosis urged general hospitals to provide beds for the tuberculous. In 1912 and 1924 the National Tuberculosis Association adopted resolutions in favor of using general hospitals for tuberculous patients. In 1920 and 1921 the American Medical Association and the American Hospital Association adopted such resolutions. Probably the most recent action on this subject was by the National Tuberculosis Association and the American Hospital Association. In June 1938 a committee of the National Tuberculosis Association with Dr. Charles Hatfield of Philadelphia as chairman made a report strongly recommending the use of general hospitals for the tuberculous. The manuscript for a bulletin on this subject has recently been prepared by Dr. W. H. Oatway of the University of Wisconsin for the American Hospital Association. This is the most complete presentation of the subject that has been made to date. It not only gives the reasons for the use of general hospitals for the tuberculous but also presents a procedure which should be carried out in every hospital that admits tuberculous patients.

Already a good many general hospitals in this country have established tuberculosis services. In fact in 1935 the American Medical Association presented the report of an extensive survey which showed that 418 hospitals in the United States have tuberculosis services and that in a single year approximately 37,000 patients were admitted to them.

The modern treatment of tuberculosis is such that removing patients to isolated places is no longer necessary. Any general hospital that is adequately equipped or can be so equipped is satisfactory for the treatment of this disease, provided nurses and physicians well informed and qualified in the treatment of this disease are in charge. In other words, a division of the hospital can be operated with the same effectiveness in the treatment of tuberculosis as a sanatorium.

The contagiousness of tuberculosis was clearly recognized and discussed nearly 2,500 years ago. The experimental work of Villemin, Colnheim, Koch and the epidemiologic studies of Budd and others proved beyond doubt that tuberculosis is contagious. This fact probably accounts for the statement in the report of the survey in question to the effect that the isolation of the tuberculous has not been accomplished. Recently careful observations have proved beyond doubt that tuberculous patients in hospitals and sanatoriums transmit tubercle bacilli to members of the personnel. Moreover, there is no reason to doubt that they transmit bacilli to other patients. In seeking appropriations for the building of sanatoriums in this country, one of the main arguments was and still is that the tuberculous patient who has the disease in the contagious stage should be removed from his home in order to prevent the spread of tubercle bacilli to the members of his family and other associates. It is ridiculous to consider that a disease which is contagious while the patient remains in the home is not equally contagious when the patient is transferred to a hospital.

The control of tuberculosis in many parts of the world has been so effectively conducted that at present more first infections occur in adult life than in the earlier years of life. For example, Heimbeck of Oslo found that approximately 50 per cent of the students of nursing reacted to the tuberculin test on entrance but that on graduation, after having taken a tuberculosis service, 100 per cent reacted to the test. In this country Geer found that 30 per cent of the entering students under his observation reacted to tuberculin, while 100 per cent of the same group reacted on graduation. These students were subjected to exposure to tuberculosis in a special service for this disease in a general hospital. Boynton found that the rate of tuberculosis infection is a hundred times greater among student nurses in a general hospital service than among students in a college of education and 500 times greater among student nurses in a special tuberculosis service than among students in a college of education. Moreover, when students of nursing and medicine become infected with tubercle bacilli, in a considerable number pulmonary lesions develop demonstrable by x-ray examination; in some clinical tuberculosis, such as pleurisy with effusion, develops, and a few die soon of acute forms of the disease, such as pneumonia, meningitis and miliary tuberculosis. Ross of Manitoba has reported 135 students or graduates in nursing who have been treated in his institution. He says: "Scores of students of nursing lose health and life through hospital-contracted tuberculous infections. Practically all students become tuberculin-positive during their course, showing that they have become infected even if disease should not follow. The hospital cannot avoid responsibility for the infection of nurses until the utmost of medical and nursing science has been used to prevent it."

In Saskatchewan Ferguson found that twelve times as many students or recent graduates in nursing fall ill with tuberculosis as other persons in the general population and eight times as many as among normal school students of about the same age as the nurses.

Heimbeck of Oslo has reported the highest percentage of student nurses falling ill with tuberculosis during training in a general hospital with a tuberculosis service.

Myers, Diehl, Boynton and others have recently called attention to the fact that in 9.6 per cent of medical students who took a tuberculosis service and became infected, so as to react to the tuberculin test, lesions developed in the lungs which could be demonstrated by x-ray films or which caused illness during the brief period of their observations. Among students of nursing who took a tuberculosis service and became reactors to tuberculin, such lesions developed in approximately 11 per cent. In addition to those in whom demonstrable lesions developed within a few months or a few years, all others who became infected have primary tuberculous complexes in their bodies and therefore are potential tuberculosis patients.

With this evidence and much more that might be cited, the time has arrived when one can no longer afford to treat tuberculous patients in general hospitals without making adequate provision for the protection of the personnel. In addition to the responsibility that every hospital should assume for the health of its personnel, there is a legal aspect which is looming large in this country and has become a serious reality. In several states tuberculosis has been placed on the occupational disease list and in others such action is being contemplated. Awards have been drawn by industrial commissions for a good many members of hospital personnel during the past few years.

In the earlier resolutions adopted by various organizations with reference to general hospitals admitting tuberculous patients, the danger to the personnel was minimized or ignored. How-

ever, the recent evidence of the spread of tuberculosis to members of hospital personnel has been so overwhelming that a definite account was taken of the dangers in the 1938 report of the Committee of the National Tuberculosis Association and the recent *Bulletin of the American Hospital Association.*

BACKACHE, MERALGIA PARAESTHETICA AND POSSIBLE SYMPATHETIC NERVOUS SYSTEM TRAUMA

To the Editor:—A married white woman aged 27 first experienced an attack of low back pain, acute and cramping in nature with radiation down the right thigh, at 19. She attributes the attack to lifting. It subsided in a few days with bed rest and local heat. The only previous trauma she can recall was a fall from a tree at the age of 14, the fall not being followed by disability. At the time of the first attack two orthopedists recommended spine fusion for tropism of the articular facets of the fifth lumbar vertebra. The operation was not performed. Following this attack and for the next six years she experienced similar attacks recurring at intervals of roughly three months. Precipitating factors were unusual strain as in lifting, golf or tennis, although at other times she could perform these acts with impunity. The duration of the attacks varied from a few days to two weeks, usually responding to time, bed rest and local heat. When conservative measures failed she submitted to osteopathic maneuvers, which seemed to give relief. She found it advisable to sleep with a 1 inch plank under the mattress. The last attack began in January 1937. While sitting in a theater her back suddenly began to hurt and on attempting to arise she found that pain prevented her from straightening. The low back area seemed cramped into a knot and all trunk and thigh movements were painful. At this time there was no sciatic radiation. Passive flexion of the thighs and pelvic rocking resulted in pain in the low back area and this area was tender to deep pressure. Her most comfortable position was lying with the legs flexed on the thighs and the thighs flexed on the trunk. Conservative measures were tried for four weeks but were unsuccessful and the patient was then hospitalized. Physical and neurologic examinations were negative except as noted and absent ankle jerks. Gynecologic examination was negative. The blood count was normal, urinalysis negative, blood Wassermann reaction negative, blood sugar 95 mg. per hundred cubic centimeters, nonprotein nitrogen 25 and cholesterol 150. Spinal fluid pressure was 70 mm. of water, protein not elevated, gold curve flat, cells 5, Wassermann reaction negative. Reversed Queckenstedt showed that no block was present. X-ray examination showed faulty articulation of the articular facets of the fifth lumbar vertebra with the sacrum. The low back pain subsided after two days on a Bradford frame although straight leg raising still caused pain in the low back area. A modified Albee spine fusion was then done, the graft being taken from the left iliac crest, splintered and laid in the bed. The wounds healed by first intention. During the postoperative period she did not complain of pain in the operative site as much as pain in the anterolateral aspect of the right thigh in an area about 2 inches below Poupart's ligament nearly to the knee. This pain was burning, sticking, tearing and digging in nature. It was quite constant although worse at night. On neurologic examination this painful area was found to correspond to the distribution of the lateral femoral cutaneous nerve. The area was hyperesthetic and firm touch was painful. The patient described it as the kind of pain produced by pressing on a carbuncle. Even light pressure, as from clothes, could not be tolerated long. Paresthesias were present in this area. Outside this area there were no neurologic changes except for the absence of ankle jerks bilaterally. Muscle tone and strength were equal and normal. A diagnosis of meralgia paraesthetica was made and in September 1937, the right lateral femoral cutaneous nerve was interrupted at its exit from the fascia, a piece excised and the proximal stump injected with absolute alcohol. For the next four days there was nearly complete relief except for occasional shooting pains similar to those experienced before the operation. Histologically the excised nerve showed "degenerative changes." Five days after the operation the entire picture recurred with pain as constant and severe as before. Two subsequent operations were performed peripherally. In October 1937 the nerve was interrupted in the right iliac fossa with no effect on the pain. In January 1938 the stump of nerve left at the first operation was found tightly bound down as it passed through Poupart's ligament. The end was bulbous. It was freed and cut back as far as possible with no effect on the pain. I might add that the first and third nerve operations were done only after procaine blocking had shown that they should be successful. During this entire period the patient had been experiencing constant pain in the low back area and stereoscopic roentgenograms showed that fusion was not complete. In March 1938 studies with iodized oil showed no block. Alcohol injections into the lumbar dorsal roots were attempted but the nerves could not be reached because of the presence of the fusion. Epidural injections gave no relief. In May 1938 typhoid vaccine fever therapy resulted in exacerbation of the pain. The patient was taking 3 grains (0.2 Gm.) of codeine and 2 grains (0.13 Gm.) of morphine daily without marked effect. She was going downhill physically. In July 1938 spinal anesthesia stopped the pain for its duration. Laminectomy over the lumbar roots was performed and the nerves were found to be normal except for a few arachnoidal adhesions, which were cleared. The patient experienced moderate relief for about one week. In August 1938 a high thoracic chordotomy was performed. Since then the patient has had no pain in the right thigh or the low back area. About one week after the operation, however, she began to experience constant burning pain in the palm of the right hand. The pain was digging, tearing and crushing in nature. Exposure to cold air made the hand cyanotic; exposure to warm air caused it to become red and swollen. All movements are painful, although they could be performed. The area is hyperesthetic. The only relief that can be obtained is by immersion in cool, not cold water. The skin is macerated. There is no vesiculation or ulceration and the nails appear normal. The dorsum of the hand is not affected. Application of a tourniquet to obstruct the venous return increases the pain. Obstruction of the arterial supply does not increase the pain but it does not relieve it. The patient readily agreed that she could not continue to take narcotics and although she experienced the usual withdrawal symptoms she stopped immediately without having to taper off. Barbiturates at night are her sole medication. Thiamin chloride, 3,000 units daily, is being given. Incidentally there are no neuropsychiatric determinants in this case and a psychiatric diagnosis is untenable. If this is causalgia could it have been caused by traumatism to the nerve roots at the time of the chordotomy? From the literature I have the impression that this condition is produced only by lesions more peripherally. If the damage is to the nerve roots would alcohol injections into these dorsal roots be more rational than stellectomy? Is stellectomy or destruction of the stellate ganglion by alcohol always followed by a Horner's syndrome and if this syndrome intervenes is there any possibility of its being severe enough to impair vision? What would be the order of investigation and procedure which would be least likely to injure or mutilate this patient without unduly prolonging her pain? Is periarterial sympathectomy as described by Leriche still being used? If this is not causalgia would you give the differential diagnosis and outline of therapy? M.D., New York.

ANSWER.—The detailed history, with extensive and apparently accurate clinical and laboratory studies, leaves little that can be recommended from the standpoint of further examination.

The initial complaint of low back pain with sciatic nerve radiation following a strain from lifting, and with subsequent attacks which were often precipitated by lifting, golf or tennis, could best be explained on a mechanical basis, such as retropulsion of an intervertebral disk, without actual rupture of the posterior fibers of the annulus fibrosus. Symptoms may be relieved under these circumstances when the muscle spasm resulting from impingement of the bulging disk on a nerve root is relieved, permitting the fibrocartilaginous disk to reassume its normal contour. It now seems probable that in a considerable proportion of the cases in which there is intermittent backache with sciatic pain the pathologic condition is that which has been described. The presence of a few arachnoidal adhesions about the lumbar nerve roots may be explained as secondary to this intermittent mechanical irritation.

It is more difficult to explain the subsequent symptoms and signs of lateral femoral cutaneous nerve irritation and the painful manifestations in the right upper extremity. The onset of the so-called meralgia paraesthetica within a few days after an operation which was predicated to cure the low back pain and the occurrence of acute pain and vasomotor phenomena in the right hand following the thoracic chordotomy, which apparently resulted in relief of pain in the areas of which the patient had previously complained, does definitely suggest neuropsychiatric factors in spite of the fact that they are so definitely denied. Addiction to morphine must be considered as a possible motive for influencing the mind in the development of a series of painful symptoms which might entitle the patient to receive a drug which her system may have demanded. The possibility that she may be obtaining morphine although it is no longer administered to her by those in attendance cannot be ignored without exhaustive attempts to determine this fact.

If there has been no mistake in interpreting the symptoms and signs which have been supplied, the painful phenomena of the right hand can be explained as a result of traumatism to the sympathetic nervous system. The symptoms described may be those of an atypical erythromelalgia or Raynaud's disease. Attacks of similar painful phenomena have been observed following surgical sections of sympathetic nerve trunks and have been attributed to the development of small neuromas at the cut end of the sympathetic nerve fibers. The chordotomy must have involved some of the tracts of the sympathetic nervous system in the upper thoracic spinal cord, and contraction of scar tissue about sympathetic nerve fibers may be responsible for the symptoms.

Any treatment which can be recommended would be largely hypothetic. Excision of the stellate ganglion has frequently resulted in relief from symptoms such as those described. Accurate selection and removal of this ganglion is followed by the development of some degree of enophthalmos, narrowing of the palpebral fissure and contraction of the pupil of the eye on the operated side. This Horner's syndrome is not sufficient contraindication to the operation if removal of the ganglion offers a reasonable prognosis for symptomatic relief. If the patient is willing to permit the isolation of the stellate ganglion with local anesthesia, a therapeutic test should be carried out before undertaking its excision. After the ganglion has been injected with procaine hydrochloride, the hand may be exposed to cold air or water and subsequently to heat to determine whether or not the procaine block has prevented the recurrence of pain and of the vasomotor phenomena. In the event that such an injection does relieve these symptoms, it would appear logical to proceed to remove the ganglion. Periarterial sympathectomy as described by Leriche has for the most part been discontinued as a therapeutic measure.

CHILDBIRTH AFTER THIRTY—INFANTILE UTERUS—FEAR OF PREGNANCY

To the Editor:—1. What is the present tendency in scientific thought relative to the prognosis of pregnancy in a physically healthy woman after the age of 30 years? I have felt that such a woman with normal measurements and satisfactory obstetric care would have only slightly if any less chance of giving birth to a normal, healthy child than a woman younger. There seems to be a tendency, however, to discourage pregnancy after the age of 30 or 35 unless the conditions are absolutely ideal. Some of the childless marriages appear to be explained adequately in the minds of laymen by the diagnosis of "sterility" without tangible evidence of the condition. 2. Would a physician's diagnosis of "infantile uterus" without other evidence of pelvic disorder be a possible indication for endocrine therapy? 3. Should a woman who appears to have no other contraindication to pregnancy in her thirties except for fear of labor be allowed to adopt a child? Would it not be better to give endocrine treatment where indicated as well as help for unsatisfactory attitudes with the hope that such a woman can have her own child? On the other hand, should a woman who has such a fear of pregnancy and who is so far removed from satisfactory obstetric care that her condition in labor might be hazardous be allowed to rationalize her supposed biologic deficiency?

M.D., Nebraska.

ANSWER.—1. A physically healthy woman, after the age of 30 years, if her husband is potent, can have as many babies as she desires and her chances of giving birth to normal healthy offspring are just as good as in a younger woman. Women after 40 have had healthy children with relatively simple labors, although it must be said that complications are a little more common after this age. Such complications, however, are amenable to modern obstetric treatment and fear of them should not restrain women from bearing children.

2. The treatment of infantile uterus, at the present time, is unsatisfactory with and without endocrines. Conflicting reports are on record regarding the results in the use of estrogen with or without progestin or gonadotropic substance. Recently there has been reported some success in increasing the blood supply of the ovaries by making omental grafts on them, thus establishing a collateral circulation. The better blood supply, it is said, developed the uterus.

3. In the first place, proper education of a woman who has tocophobia will almost always succeed in removing groundless fears. Modern obstetrics has made so much progress that no woman should fear having a baby. In the second place, the adoption of a child is a mutual benefit. Both the mother and the child receive the greatest possible good, and it is probable in this case that the presence of one child may remove the unnatural apprehension of the mother. Distance from available obstetric service should not form any part in the discussion of the indications for obstetrics. Good roads, the automobile and the generosity of the profession serve to handle the situation satisfactorily.

SYPHILIS AND PULMONARY TUBERCULOSIS

To the Editor:—What is the current opinion on the treatment of syphilis complicating pulmonary tuberculosis? Are there any comprehensive articles on the subject?

M.D., Virginia.

ANSWER.—A recent report by Smith (*Am. J. Syph., Gonor. & Ven. Dis.* **22**:72-81 [Jan.] 1938) as well as one by Padget and Moore (*Am. Rev. Tuberc.* **33**:10 [Jan.] 1936) should be consulted.

In the past there has been a tendency to be conservative in treating syphilis in a tuberculous subject. Apparently this point of view is changing. Some investigators think that carefully controlled treatment of syphilis is even beneficial to a concomitant tuberculosis. Smith found that progressive tuberculosis is not more frequent in the treated syphilitic patient than in similar groups of nonsyphilitic tuberculous patients. The treatment of syphilis seems to lessen the frequency of progressive tuberculosis. Padget and Moore feel that the question is not entirely settled. It probably is well to use extreme care in treating a syphilitic patient with concomitant tuberculosis. Any remedy likely to set up reactions would be contraindicated. Either neoarsphenamine or mapharsen would be preferred for the arsenical. A bismuth salt causing little physical inconvenience is preferable, provided at the same time it furnishes an adequate antisyphilitic effect with little or no deleterious effects. For a hospitalized patient such a preparation would be an aqueous solution of sodium bismuth tartrate 2 cc. administered intramuscularly in the buttocks three times a week. For the ambulatory patient a weekly injection of a 10 per cent suspension in oil of bismuth subsalicylate is indicated. Neither preparation causes inconvenience, and each employed over a period of ten weeks would give an adequate bismuth effect for a course. The arsenicals in moderate sized doses could likewise be used in weekly injections for a term of ten weeks if no untoward contingencies arise. Probably three or four such alternating courses of the arsenicals and of the bismuth could be safely used, employing continuous treatment. Iodides are contraindicated in tuberculosis because of a possible danger of absorption of protective connective tissue walls formed around tuberculous foci.

SALINIZING AND CHLORINATING SWIMMING POOL

To the Editor:—What is the feasibility of salinizing an outdoor swimming pool to make the water isotonic or slightly hypertonic? The pool has a standard chlorinating filtration plant. Will you let me know if the water could be salinized without interfering with the chlorinization, and if so about what concentration of salt would be advisable?

AIDAN M. MULLETT, M.D., Colorado Springs, Colo.

ANSWER.—It is feasible, but fairly expensive, to salinize fresh swimming pool water. Normal sea water contains about 3 per cent of sodium chloride in solution or about 12½ tons per hundred thousand gallons. It is probable that a smaller amount would be more desirable in a swimming pool, depending of course on the clientele served.

Normal sea water can be effectively chlorinated for disinfection by the same methods used for fresh water, assuming that reasonably accurate chlorine control equipment is used and that proper tests are made for residual chlorine in the water to permit the operator to govern the rate of application of the chlorine. Another method of disinfecting sea water is by electrolysis.

PROBABLE PSYCHOGENIC SYNDROME

To the Editor:—A white man aged 25, an engineering student, weight 165 pounds (75 Kg.), height 5 feet 9 inches (175 cm.), complains of frontal headache, a sensation of pressure above the hard palate, fatigue and occasional nervousness. The headache has been present continuously for the past four years (it began in the second year of college), interfering tremendously with his ability to concentrate and making him so uncomfortable at times that he has little desire to see any one, although he is quite a good mixer and extremely cheerful ordinarily. There has never been any loss of weight, and the patient eats and sleeps well. During his schooling he had been troubled with financial worries but is now over this. He does not smoke or drink. The past history reveals an appendectomy ten years ago and a tonsillectomy two years ago. The personal history shows a tendency to worry, but there is no occasion for it at present. He does not take part in any physical activities at present. Physical examination revealed septal deviation of the nose causing a slight breathing obstruction. The lung fields were clear; the heart showed no abnormalities; the blood pressure was 135 systolic, 85 diastolic; the abdomen was normal. Neurologic examination revealed nothing of significance. The erythrocytes numbered 5,100,000 and leukocytes 8,500 with a normal differential count. The content of hemoglobin was 90 per cent. The urine was negative for albumin and sugar. The basal metabolic rate in three tests was —13.0, —11.5 and —12.0. The Wassermann reaction of the blood was negative. He has been on one-half grain (0.03 Gm.) desiccated thyroid three times a day for the past two months without any demonstrable change in his condition. Kindly make recommendations as to future therapy.

M.D., Pennsylvania.

ANSWER.—None of the symptoms described, singly or in combination, may be considered as due to any specific etiology. In fact, in many such cases there is a multiple etiology. As a whole, the case strongly suggests that the major etiologic agent is psychogenic. Because of its nonspecific nature and the suspicion of a psychic disturbance, the immediate approach is one aimed at exclusion of the more common organic causes.

Nothing about the case suggests migraine. In the absence of cranial trauma, a post-traumatic syndrome may be excluded. A thorough otologic investigation is imperative, and it should not be forgotten that such a syndrome may be caused by defective sinus drainage without active infection (Parkinson, S. N.: *Arch. Otolaryng.* **23**:344 [March] 1936, and **24**:594 [Nov.] 1936; THE JOURNAL, Jan. 21, 1939, p. 204). Any operative procedures on the sinuses should be avoided unless unequivocal pathologic changes are found.

A thorough ocular and oculomotor examination is essential, including emphasis on the activity of the intrinsic as well as the extrinsic eye muscles. A complete neurologic examination is indicated, including visual fields and cranial roentgenography to exclude intracranial tumor. A lumbar puncture is perhaps to be avoided because of the probability of postpuncture reaction in this patient. If, however, anything in the examination suggests an intracranial lesion, a lumbar puncture then becomes imperative.

After exclusion of organic causes, the psychic status of the patient should be investigated. This requires first of all an estimate of the personality basis and secondly an investigation of the immediate causative factors. The latter may after four years be somewhat obscured. The patient's symptoms now may be a habitual reaction to earlier incompatibilities. Often a combination of stresses will be found in the social, sexual, economic, intellectual and other spheres. As tact, skill, experience and

patience are necessary for such an investigation, a specialist in this field should conduct it. Often the revelation of the cause acts as a cure when understood and accepted by the patient. Prognosis will depend largely on the personality basis of the patient.

Sedatives per se are contraindicated as well as opiates and analgesics. Thyroid is of little or no value.

INTELLIGENCE QUOTIENT

To the Editor:—Have enough mass tests of the intelligence quotient by the Stanford-Binet and other methods been made to estimate the approximate number and percentage of the higher intelligence levels throughout the country or in New York? Can you tell me the approximate percentage, ratio or number of persons, or children alone, with intelligence quotients at levels of every 10 points including and above 160? What is the highest intelligence quotient recorded? At what age can the intelligence quotient first be considered as relatively stable for the rest of the child's testable age?

EMIL ROTHSTEIN, M.D., Brooklyn.

ANSWER.—Although many data have been collected concerning the Stanford-Binet intelligence tests, there are no complete data available of the approximate ratio or number of persons with intelligence quotients at every level. This would be possible only if the entire population were tested. The reports by Terman, Gesell and Pintner are informing. Most psychologists believe that an intelligence quotient of 190 is extremely rare. The relatively most stable period of establishing the intelligence quotient by the Stanford-Binet test is between the ages of 6 and 10 years.

SOAP LAKE WATER FOR THROMBO-ANGIITIS OBLITERANS

To the Editor:—Do you have any information regarding the treatment of Buerger's disease at Soap Lake, Wash.? Presumably the patients are given baths of this water and also take water internally. I understand the government has built a hospital there for patients with this disease. We would appreciate any light thrown on the subject.

J. I. CHALEK, M.D., Minneapolis.

ANSWER.—A good deal has been written about the curative effects of water of Soap Lake for patients with thrombo-angiitis obliterans, or Buerger's disease. Several months ago one of the journals for the members of the American Legion carried an extensive article in which extravagant claims were made for the curative power of the water of Soap Lake. As far as known there has been no expert estimate by a physician of the beneficial effects of treatment of thrombo-angiitis obliterans at Soap Lake. Articles written by persons who are not physicians indicate an extreme lack of knowledge about the disease on which they write so freely.

DUCK SHOT IN EYE

To the Editor:—Have there been any reports of the effect or results following the introduction of duck shot into body tissue, duck shot at the present time being made of magnesium or an alloy of magnesium? I have a patient in whom such shot have been embedded in the orbital tissues.

PAUL G. MOORE, M.D., Cleveland.

ANSWER.—There are no reports on the effect of the introduction into the tissue of the orbit of shot composed of magnesium or its alloy. The presence of a foreign body produces well known effects, but whether or not the composition of such foreign bodies has a chemical effect on the tissue is not known.

CYSTOSCOPES

To the Editor:—What make and type of cystoscope would you advise for general diagnostic and therapeutic use in male and female?

M.D., Pennsylvania.

ANSWER.—There are many types of cystoscopes for special purposes. There are but a few that can be called universal in that they give satisfactory performances for observation, ureteral catheterization and operative cystoscopy. For general use, including the three mentioned, the Ravich universal cystoscope, which is a No. 21 French instrument, is satisfactory.

Council on Medical Education and Hospitals

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Thirty-Fifth Annual Meeting, held in Chicago, Feb. 13 and 14, 1939

(Continued from page 1189)

DR. J. H. MUSSER, New Orleans, in the Chair

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

FEBRUARY 14—MORNING

The Program of the National Committee for Mental Hygiene

DR. CLARENCE M. HINCKS, New York: For thirty years the National Committee for Mental Hygiene, thanks to the support of philanthropic citizens and great foundations, has been enabled to conduct surveys, to support research, to set up experimental demonstrations and to be active in the field of health education. There was organized three years ago the Mental Hospital Survey Committee. Dr. Samuel W. Hamilton, Dr. Grover Kempf and others connected with the group conducted studies in forty states, affecting 169 hospitals, and made surveys in three Canadian provinces.

A number of mental hospitals have attained creditable standards and compare favorably with the better general hospitals of the country, but there are institutions with arrangements that are utterly inadequate and that are a discredit to present day civilization. The average ratio of medical personnel to patients in mental hospitals of the United States is 1:259 as against the accepted standard of 1:150, and the hospitals are understaffed in relation to nurses and other personnel. Only two states are free from overcrowding in mental institutions. To make provision for the hospitalization of persons requiring institutional care but not now receiving it, there are needed approximately 130,000 additional mental hospital beds in the United States. The number of beds for all classes of mental patients varies from 175 to 688 per hundred thousand in the various states. Political interference involves the personnel of hospitals with every change of administration in fourteen states and occurs occasionally in at least eight more. This circumstance constitutes a greater threat to sound administration than shortage of personnel and equipment. The average expenditure in the United States for the treatment of the mentally ill is 7.02 per cent of the states' income, with a range of from 2.83 per cent to 18.49 per cent. One state spends $1.10 a day per patient for mental hospitalization, with another appropriating only 31.03 cents a day. The latter sum prohibits of course any genuine attempt to provide scientific and humanitarian services.

These facts are disconcerting and present a challenge to the nation to place essential services for the mentally ill on a basis in line with acceptable scientific standards. The situation demands the rating of mental hospitals to furnish the medical profession and the public with an indication of the status of institutional facilities in their particular state or locality.

The time has come, perhaps, for a reshaping of mental hospital arrangements. To meet the requirements of the aged and other groups, there are needed institutions with distinct hospital groupings, with various units specially designed, located and staffed for their specific purposes, with separate budgets, but with activities correlated and administered by a medical superintendent and his assistants.

While the national committee has had a profound interest in adequate hospitalization, its major concern has always been the prevention of mental disorders. We know that, in connection with the younger generation, 4 per cent will at some period in their lives enter mental hospitals as patients afflicted with insanity; that 2 per cent are mentally deficient, with insufficient capacity to compete on equal terms with their fellows; that 1 per cent will become delinquent, and that at least 8 per cent will be handicapped because of marked emotional instability, because of twists and distortions of personality and because of

nervous breakdowns and other forms of maladjustments. In other words, there are more than 5 million children in our schools today whose outlook is dark indeed because of precarious mental health, 5 million children who, in the absence of preventive measures, will ultimately cost this country hundreds of millions of dollars in the upkeep of mental institutions, jails and relief agencies and who are destined to add greatly to the sum total of human unhappiness and inefficiency.

Prevention can be fostered through cooperative undertakings with the teaching profession and through the activities of physicians in the education of patients and the public in mental health matters. There is presented here a challenge to medical men in the extension of their educational efforts with the public, to include matters relating to mental as well as physical hygiene.

The national committee is appreciative of the fact that trained personnel is requisite for all mental hygiene undertakings. It has given attention to the training of nurses, social workers and teachers. There is need for the continued activities of the Council on Medical Education and Hospitals of the American Medical Association in connection with internships in mental hospitals and related efforts. Of fundamental importance is the conduct of educational work to reach the men who are now actively engaged in medical practice throughout the country.

The problems presented by mental disorders will become more and more acute unless adequate arrangements are made for the prosecution of research to point the way to more effective programs of prevention and treatment. The national committee has been sensitive to this need for research and, through annual grants from the Scottish Rite Masons of the Northern Jurisdiction of the United States, is subsidizing eighteen research projects in dementia praecox. In addition a study has been made of the present status of research and the possibilities for further development in the publicly supported mental hospitals of the country. It was found that twenty of the 273 public institutions were well organized and staffed for investigatory work and that an additional thirty-two hospitals offered distinct possibilities for research. However, too little attention has been devoted to research activities in this domain. It is interesting to note that, in the field of industrial research, there are in this country 40,000 workers in 1,600 laboratories involving an annual expenditure of 300 million dollars. Psychiatric research has less than 1 per cent of such resources and personnel. What a contrast, and what a challenge to effect a more even balance in our civilization!

Fundamentals of Industrial Hygiene

DR. T. LYLE HAZLETT, Pittsburgh: Industrial hygiene may be defined as the application of medical science to health and its preservation among the working population with the object of establishing the most healthful environment for the worker. Medical service in industry can be divided into three cycles. The first cycle was prior to 1910, when such service was practically unknown. Employees injured while at work were sent to the office of the nearest physician, and the management gave little thought to the surgical care and rehabilitation of injured employees. The second or surgical cycle was predominant from 1910 to 1925, during which years came the development of the group system of production, with an increased concentration of workers. The greatest source of traumatic injuries during these years was in industry, and the result was the enactment of compensation laws. It became apparent in 1913 that many injuries could be prevented, and in that year the National Safety Council came into existence. The third cycle, which began in 1925, can be termed the medical-engineering cycle, since it became evident that many conditions existed in industry that had some bearing on the health of employees. During the last few years more attention has been given to the working environment in its relation to the well-being and conservation of health among workers. Thus there has been opened a new field of preventive medicine, with an industrial application. This requires active participation by physicians working in cooperation with engineers to determine actual measurements of existing conditions so that adequate control measures may be instituted. Recently some twenty-one states have added occupational disease acts to their compensation laws and there seems to be a gradual tendency to increase the number of so-called occupational diseases. In addition, many cases are being carried to the civil courts and are a subject of much concern.

In 1936 an industrial hygiene department was established at the University of Pittsburgh School of Medicine with the object of providing undergraduate and graduate instruction in industrial medical problems and establishing facilities for research on specific industrial problems as they pertain to the health and well-being of workers. In conjunction, an analytic laboratory has been established and hospital facilities are available for the investigation of occupational diseases, together with fellowships for graduates who desire to do such research work on industrial medical problems. An intensified graduate course of one week was offered last year and was well received.

Perhaps 90 per cent of the medical graduates have in the first years of practice some industrial or insurance contacts which bring them into the compensation field. Consequently there has arisen the necessity for extending the curriculum in our medical schools to provide instruction in industrial hygiene in its application to industrial life and to preventive medicine in industry. This can be done only by making this subject an entity in present day medical education. The part the physician should take and the responsibilities he should assume may be presented under four captions: 1. Safeguarding the health of the industrial workers in relation to their working environment. This includes air hygiene, lighting, noise, fatigue syndrome, sanitation, and placement of workers both from a mental and from a physical standpoint; making periodic examinations, especially of workers in known health hazards, and making definite recommendations to the management for the elimination of any unhealthful practices. 2. Medical care of occupational injuries and diseases and emergency medical care of nonoccupational illnesses occurring while the worker is on duty. 3. Research work. The constant development of new processes, new materials and new combinations of materials and their effects on the human body present to the graduate in medicine today his greatest opportunity in the study of occupational environment and in exploring new frontiers. 4. Health education. Much can be accomplished in an educational manner on the subjects of tuberculosis, heart disease and syphilis, for no group is more easily accessible or more desirous of knowing simple health facts than the industrially employed. If physicians do not realize the value of this avenue of transmitting worthwhile medical knowledge they will be acting contrary to the concepts of preventive medicine in its fullest extent.

It behooves them to assume the responsibility of guiding industry in its intra-industrial medical problems. Medical teaching institutions must give serious consideration to additional instruction so that the students may be able to assume their place in this age of complex and changing relationships in industrial life.

The Relation of Anesthesiology to Medical Education

DRS. RALPH M. WATERS, H. R. HATHAWAY and W. H. CASSELS, Madison, Wis.: This paper will be published in full in THE JOURNAL.

Tenure of Members of the Faculties in the Medical Schools

A. J. CARLSON, PH.D., Chicago: A questionnaire was mailed to the deans of the eighty-seven medical schools in the United States and Canada. Returns came in from eighty-five. This nearly 100 per cent response, I believe, stands as a record, and to it any merit in my summary and comments is largely due.

It appears on the returns that in fifteen medical schools indefinite tenure obtains at all ranks. I do not believe this is true. There must have been carelessness in checking. There should not, in my opinion, be initial indefinite tenure at the instructor rank. One should have a probationary period of from three to six years, during which time the instructor demonstrates his capacity in teaching and research. The large

number of schools, thirty-four, listed as having annual or biannual appointments of all ranks is also misleading. This group includes the medical schools in state universities, where state laws stipulate this kind of tenure. Actually, even on these faculties the full professor and in some cases the associate and assistant professor have, by practice, indefinite tenure. Indefinite tenure is accorded in eleven schools only to the full professors, in seventeen schools to the associate professors and in twelve schools to assistant professors also.

Apart from the importance of freedom and tenure for the highest performance in teaching and research, annual, biannual or term appointments, after the period of apprenticeship has passed, result in a less careful scrutiny of the performance of staff members by such responsible officers as chairmen of departments and deans. Also the failure to reappoint is a too ready and tempting door of exit in case of personal jealousy and prejudice, which one does not like to drag into the open, as would be done if discontinuance of service had to be preceded by a real hearing on the quality of performance.

Dismissal is accomplished by faculty vote in three schools, after recommendation of a committee of the faculty in twenty-two, on recommendation of the chairman of the department in eighteen and after a hearing before a committee in six. Forty-eight schools make no provision for a hearing.

Over half of the medical schools report that no provision for a genuine hearing exists in the statutes, by-laws or traditional administrative procedures of their school. I do not think that the majority of the executive officers (chairmen, deans, presidents, trustees) are that arbitrary. I think at least some of the deans made an error in checking on this item. But there are the figures. Twenty-five schools report that there is action by the faculty or a committee of the faculty prior to dismissal. This usually implies some form of a hearing for the party under accusation. In the case of the eighteen who dismiss on recommendation of the chairman alone, the accused party may or may not have a chance to be heard. Such hearings as are afforded are a matter largely of generosity and good sense rather than of requirement by the legal setup of the school, whether public or private. Trustees or governing boards are the legal entities of the school, and these legal entities usually have the power, under state laws or articles of incorporation, to dismiss a staff member at any time, without hearing and without giving any reasons for the dismissal, just as in a business corporation. The administration of a medical school worthy of the name must be above suspicion. Star chamber methods are out. Even a professor is entitled to be judged by his peers.

In the evolution of more efficient administrative procedures in medical schools these primary elements in the problem must be kept in mind: Real teaching and high grade research are most difficult tasks. Men with the high and rare powers involved can be neither driven nor commanded. Their performance flows from within, from the light and power of the individual. The essential administrative problem is the creation and maintenance of a milieu most suited to the labors of such men. It is slowly being learned, what should have been clear without experiment, that full time service on a medical faculty, despite its significance for research, is no cure-all as regards poor teaching. Not enough clearly superior men have been attracted to the profession to staff the faculties of medicine. What is to be done, in justice to the students, with those staff members who, because of sickness, premature senility, laziness or other misfortunes, fail to perform according to the promise of their earlier years? I think that the schools should act in their cases more frequently and objectively than they do. Throwing these men out does not seem a satisfactory answer, especially if the school has used what gifts they have until they are past 40. If there is going to be some such thing as an equity in one's post in relation to performance and time, it would seem that a person who has served society to the best of his ability even for five or ten years has earned part of the financial compensation due him after a service of thirty or forty years.

(To be continued)

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 20-22. Sec., Dr. J. N. Baker, 517 Dexter Ave., Montgomery.

ARIZONA: Phoenix, April 11-12. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: *Medical (Regular).* Little Rock, June 8-9. Sec., State Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, 317 State Line, Texarkana. *Medical (Eclectic).* Little Rock, June 8-9. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Written examinations.* San Francisco, July 10-13, and Sacramento, Oct. 16-19. *Oral examinations* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, August 7, and San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, April 5-7. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Basic Science.* New Haven, June 10. *Prerequisite to license examination.* Address State Board of Healing Arts, 1895 Yale Station, New Haven.

DELAWARE: Dover, July 11-13. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: *Basic Science.* Washington, June 26-27. *Medical.* Washington, July 10-11. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, June 19-20. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, June. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Honolulu, April 10-13. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDAHO: Boise, April 4-7. Address, Dir., Bureau of Occupational License, Rm. 355, State Capitol Bldg., Boise.

ILLINOIS: *Chicago, April 11-13, June 20-22, and* Oct. 17-19. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 20-22. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: *Basic Science.* Des Moines, April 11. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Capitol Bldg., Des Moines.

KANSAS: Kansas City, June 13-14. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Louisville, June 7-9. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

MARYLAND: *Medical (Regular).* Baltimore, June 20-23. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Medical (Homeopathic).* Baltimore, June 20-21. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: Ann Arbor and Detroit, June 14-16. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 100 W. Allegan St., Lansing.

MINNESOTA: *Basic Science.* Minneapolis, April 4-5. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical.* Minneapolis, April 18-20. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Jackson, June. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, April 4-5. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: *Basic Science.* Omaha, May 2-3. *Medical.* Omaha, June 8-9. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEVADA: Carson City, May 1-3. Sec., Dr. John E. Worden, Capitol Bldg., Carson City.

NEW JERSEY: Trenton, June 20-21. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 10-11. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York, and Syracuse, June. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Building, State Education Department, Albany.

NORTH CAROLINA: Raleigh, June 19. Sec., Dr. William D. James, The Hamlet Hospital, Hamlet.

NORTH DAKOTA: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: *Basic Science.* Oklahoma City, May 15. Sec. of State, Hon. C. C. Childress, State Capitol, Oklahoma City. *Medical.* Oklahoma City, June 14. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: *Basic Science.* Corvallis, July 8, and Portland, Oct. 28. Sec. State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia and Pittsburgh, July. Sec., Board of Medical Education and Licensure, Dr. James A. Newpher, 400 Education Bldg., Harrisburg.

RHODE ISLAND: Providence, April 6-7. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 27. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Rapid City, July 18-19. Director, Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TEXAS: June. Sec., Dr. T. J. Crowe, 918 Mercantile Bldg., Dallas.

VERMONT: Burlington, June 14-16. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 21-23. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WISCONSIN: Milwaukee, June 27-30. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, March 25, page 1189.

Maine November Examination

Dr. Adam P. Leighton, secretary, Maine Board of Registration of Medicine, reports the written examination held in Portland, Nov. 8-9, 1938. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Ten candidates were examined, five of whom passed and five failed. Three physicians were licensed by reciprocity and three physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	Year Grad	Per Cent
PASSED		
Boston University School of Medicine	(1938)	88
Tufts College Medical School	(1937)	79

Book Notices

Our Common Ailment. Constipation: Its Cause and Cure. By Harold Aaron, M D, Medical Consultant to Consumers Union of United States. Cloth Price, $1.50. Pp 192, with 2 illustrations. New York: Dodge Publishing Company, 1938.

In his position as medical consultant to the Consumers' Union of the United States, Dr. Aaron has had occasion to acquaint himself with the composition of most of the laxatives, purgatives and gummy preparations which are now offered to the American people for the relief of constipation. All physicians can read the chapter on this topic with much interest and profit. Dr. Aaron has familiarized himself with the physiology of the colon so far as it is known; also the pathologic physiology of constipation. His pronouncements are unusually sane, and he is doing a service by showing people how much buncombe there is in much of what they have been told about the bowel. The book should help to clear people's minds of fear with regard to such things as intestinal autointoxication, acidosis and ptosis of the colon. It will tell them that most of what is called colitis today should not be called colitis and is not to be worried about, because it is not associated with any true inflammation or ulceration of the bowel. In these cases the bowel itself appears to be normal, but it tends to contract spasmodically and to excrete an excessive amount of mucus because of excessive stimulation by the patient's jangling nerves. Although the book was written primarily for a lay audience, it is decidedly worth reading by medical men and even by gastro-enterologists of some experience. For many patients a book like this could be useful. It will answer many of their questions and will give them many suggestions for the solution of their problem.

Allergic Diseases: Their Diagnosis and Treatment. By Ray M Balyeat, M A, M D, F A C P, Associate Professor of Medicine, University of Oklahoma Medical School, Oklahoma City, Oklahoma Assisted by Ralph Bowen, B A, M D, F.A A P., Chief of Pediatric Section, Balyeat Hay Fever and Asthma Clinic, Oklahoma City. Fifth edition Cloth Price, $6 Pp. 547, with 145 illustrations. Philadelphia: F. A Davis Company, 1938

The first edition of this book was written for the instruction of the public. The fifth edition is primarily for the general practitioner. Unfortunately the gradation from the lay to the medical textbook has been incomplete. The information included is much too detailed for any lay reader and too little for the physician The organization is poor. It is directed too much to arouse interest in scattered but practical questions rather than to give a coherent, well balanced discussion of allergy. The greatest fault probably lies in an almost complete lack of discussion of the theory of allergy, especially of the pathology and the pathogenesis of the allergic conditions. A general discussion of immunology is completely omitted. The book gives one the impression that allergic conditions of all types are in a large proportion of cases diagnosed by various types of cutaneous tests. Even in the chapters on urticaria and migraine this technic is almost completely relied on. Dietary studies through diaries and elimination diets are not given or discussed in these chapters. They are left for a brief final chapter, which is devoted primarily to recipes for wheat, egg and milk free preparations. These are excellent, but for their proper use the reader would have to consult a more thorough reference book The chapter on allergic dermatoses is weak. It is devoted largely to case reports rather than to a thorough discussion of the pathology and clinical pictures of infantile eczema, atopic dermatitis and contact dermatitis. In the chapter on treatment of intractable asthma and bronchiectasis most of the thirty-eight pages are devoted to a discussion of the technic and benefits of iodized oil instillation. All references to this are from sources favorable to this therapy. Unfavorable criticism, as the review of the literature and the work by Criep and Hampsey, is completely ignored. Because of the brevity of theoretical discussion, erroneous impressions are given through such a statement, under the brief discussion of the chemistry of pollen (page 92), as "However, it is definitely shown that the substance to which patients develop a specific sensitivity is not protein." This conclusion is not accepted by most workers. Another error, which is serious from a practical rather than an academic point of view, is the statement (page 117) that horse sensitive patients

have symptoms from furniture containing horsehair. This material as prepared for such use is not capable of producing symptoms because of the processes used (usually boiling in alkalis and soaking in solution of formaldehyde). The pollen charts of various regions are numerous and excellent. The other illustrations are often unnecessary and meaningless (the pictures of a horse, cows, hogs, sheep, rabbits, common vegetables, a bag of flour, a loaf of bread and a labeled package of cereal, all to emphasize common causes of allergy). A few well chosen words supported by statistics would serve the intelligent reader to a greater purpose.

Heart Disease and Pregnancy. By Crighton Bramwell, M.A., M.D., F.R.C.P., Physician, Manchester Royal Infirmary, and Edith A. Longson, M.B., Ch.B., D.P.H. With a Foreword by Sir Ewen Maclean, M.D., F.R.C.P., LL.D. Cloth. Price, $3. Pp. 194, with 57 illustrations. New York, London & Toronto: Oxford University Press, 1938.

This small book contains considerable information, both pertinent and irrelevant; many of the illustrations and much of the text, however, present merely the fundamentals of heart disease and might well be omitted.

The authors give a valuable analysis of the data on 350 cases of their own and compare them with series already published by McIlroy and Rendel in 1931 (200 cases), Carr and Hamilton in 1933 (500 cases) and Watson in 1933 (240 cases). Of the authors' series 89.7 per cent were rheumatic, 4 per cent were congenital and 6.3 per cent were miscellaneous. Ninety-five patients had a trivial to slight amount of heart disease and three of these (3.2 per cent) died. These were called class 1. The other 284 had more severe heart disease, and of these twenty-two (7.8 per cent) died. These were called class 2. Thus there was a total mortality of twenty-five of the 379, or 6.6 per cent. There were 156 primigravidas; two of forty-four of class 1, or 4.9 per cent, died and eleven of 112 of class 2, or 10 per cent, died, making a total death rate among the primigravidas of 8.6 per cent (thirteen of 156). There were 223 multiparas; of fifty-one belonging to class 1 one died (1.9 per cent) and of 172 belonging to class 2 eleven died (6.4 per cent), making a total death rate among the multiparas of 5.3 per cent (twelve of 223). There were twenty-four patients with auricular fibrillation in the whole series of 379 cases. The death rate among these was 29.2 per cent as compared with the total mortality of 6.6 per cent.

As the result of their observations the authors were inclined to modify their previous opinion and to believe that "although auricular fibrillation does undoubtedly add considerably to the risk of pregnancy it does not constitute a bar to pregnancy provided the patient can be kept under observation and receive adequate treatment." Their case 113 is of interest in this respect:

> A working-class woman who was in the Manchester Royal Infirmary, with rheumatic heart disease, at the age of 16 in 1913 came under our care with auricular fibrillation, mitral stenosis and great cardiac enlargement, following her third confinement in 1923. Normal rhythm was restored with quinidine and was maintained for two years in spite of a further pregnancy with a normal confinement in 1924. In 1925 fibrillation recurred, and we therefore terminated her fifth pregnancy. Between 1926 and 1930 another pregnancy was terminated, and she had two natural abortions. In 1931 she again became pregnant but felt so fit that she begged us to allow pregnancy to continue. With much reluctance and no slight misgiving we ultimately gave our consent. She was delivered by cesarean section. Convalescence was uneventful. Six years have since elapsed and there is no evidence that her cardiac condition has been aggravated by this confinement. This woman is able to look after her home and three children single handed. To our knowledge she was fibrillating fourteen years ago and has been fibrillating continuously for twelve years. During that time she has given birth to two healthy children in addition to having two therapeutic and two natural abortions.

The authors have never used quinidine in the treatment of fibrillation in pregnant women, partly because of the danger of producing abortion but chiefly because the type of case with which they were dealing was not thought suitable for quinidine. With respect to congestive heart failure they write:

> Twenty-six of the patients in our series exhibited evidence of heart failure with venous engorgement and edema at the time they first came under observation. Of these, ten died prior to or soon after confinement and four others are known to have died within the next six years, giving a total mortality of 53 per cent. Expressed in another way, out of fifteen of our patients who died from cardiac causes, either prior to or within six months of confinement, ten had exhibited signs of congestive heart failure when first seen. These figures speak for themselves.
>
> The prognosis, however, is not always unfavorable, for five of our patients who developed congestive heart failure, during the later months of pregnancy, responded satisfactorily to treatment. Success in treatment depends chiefly on the early recognition of signs of failure. For this reason we wish to emphasize the importance of adequate ante partum supervision, especially with a view to detecting heart failure in its initial stages.

Of 312 patients with valvular disease, 260 had mitral stenosis alone. The others had mostly aortic valve disease alone, of which there were six, or aortic complicating mitral. The mortality was highest in the uncomplicated mitral stenosis cases, with twenty deaths in 260 cases. There were only two deaths in the other fifty-two cases.

The authors disagree entirely with the statement expressed by Donovan in 1936 that congenital heart disease constitutes a contraindication to pregnancy. Only one of the sixteen cases caused them any anxiety and that case, Fallot's tetralogy, was not fatal. There were in the total series only five cases of thyrotoxic heart disease, and only twenty with a systolic pressure of 140 mm. or higher. Not a single case was diagnosed as cardiovascular syphilis. Their experience with therapeutic abortion they summarize:

> Termination of pregnancy will not cure heart disease. It should only be performed when treatment of the heart condition has failed and when the continuance of pregnancy endangers life or entails grave risk of producing a permanent aggravation of the cardiac disability. In other words, in patients with heart disease the indications for therapeutic abortion are identical with the contraindications to pregnancy. When such patients are seen during the first three months, emptying the uterus is a relatively safe procedure. After the end of the third month the risk is greatly increased, in view of the danger from shock and hemorrhage. Then the wisest course is to allow pregnancy to continue until the child is viable, and to deliver by cesarean section.
>
> Therapeutic abortion was performed in twenty-four of our cases (7 per cent), in eight on account of auricular fibrillation, in two for heart failure and in the other fourteen on account of the poor general condition of the patient or the fact that they manifested increasing respiratory distress, which did not respond to treatment. Two of these patients died (patients 175 and 260).

In this country there is a belief that cesarean section is to be avoided in most cases.

At the end of the book the authors write: "Taking all aspects into account, we consider that it is usually unwise for a woman with a slight heart lesion to have more than two children, and when the lesion is of moderate severity she should be content with one."

Manual of Diets, Montefiore Hospital, New York City. Third edition. Paper. Pp. 33. New York, 1938.

Although considerations of diet and nutrition are important in the management of any disease, not many hospitals have a formal committee on nutrition. The Montefiore Hospital of New York has such a committee, and for the guidance of physicians and other members of the staff this committee compiled a manual of diets, now appearing in the third edition. The manual sets forth a series of standard dietary prescriptions. Each diet appears in outline form, usually on a single page or less, and the information provided includes a list of indications, characteristics, foods allowed, foods to be avoided and a typical menu for one day. It might be well if future editions of this useful manual were to include menus for several days. Probably this isn't necessary, but such information would be useful to practitioners who desire to give suitable instructions for patients in the home. There are no data provided on the cost of special diets but it is mentioned that the average cost of a special diet is approximately 50 per cent greater than the average cost of a general or routine diet.

Electrotherapy and Light Therapy. By Richard Kovács, M.D., Clinical Professor and Director of Physical Therapy, New York Polyclinic Medical School and Hospital, New York. Third edition. Cloth. Price, $7.50. Pp. 744, with 308 illustrations. Philadelphia: Lea & Febiger, 1938.

The publication of the third edition of this textbook within five years is an indication of its popularity and usefulness. An examination of the extensive revision and enlargement of this edition also reveals that the author has included many of the recent advances in the rapidly growing field of physical therapy in general and electrotherapy and light therapy in particular. There are enlargements of sections on newer methods in electrical treatment, with two new chapters on short wave diathermy and a new chapter on artificial fever by electrical means, as well as revision of the whole volume. While the book was primarily intended to present that part of modern physical therapy which practicing physicians may themselves carry on in their office, the scope is so broad that

it should be of value to students interested in a nonmathematical survey of the physics of electricity and radiant energy and the physiologic principles involved in the production or use of electrical and radiant energy in the body. The book begins with basic electrophysics, avoiding a complicated mathematical approach, and leads up to the physics of various electromedical currents and radiant energy, along with a description of the devices producing them and their physiologic effects. The description of the basic physiology of electrical stimulation and the theories of bio-electric currents is more detailed than that in most physiology textbooks. There is a valuable new chapter, for instance, correlating electrophysiology with electrotherapy and an expansion of many chapters on general theory such as those on galvanic current, electrophoresis and chronaxia. The last section of the book is devoted more particularly to applied electrotherapy and light therapy for the guidance of the physician. These details of clinical application seem quite complete, and they correlate the use of simpler methods of physical therapy with the more complicated electrical ones. Among the most important aspects of the book seem to be the well rounded discussions of various methods and theories, as well as the many references and the expanded glossary included.

Diseases of Women. By Ten Teachers under the direction of Clifford White, M.D., B.S., F.R.C.P. Edited by Sir Comyns Berkeley, Clifford White and Frank Cook. Sixth edition. Cloth. Price, $6. Pp. 492, with 158 illustrations. Baltimore: William Wood & Company, 1938.

In this edition the section on the physiology and disorders of menstruation has been completely revised. These data in their new form are lucid, helpful and as accurate as a simplified version can be. The volume presents fewer of the homely old British usages, such as the brisk purge for any and all contingencies, the rather loose application of dilation and curettage, the tardy adoption of the intravenous route for the administration of fluids and the uterine injection of hot glycerin for acute endometritis. One might say that the book has been considerably polished up. Most important in this connection is a complete capitulation to the argument for the conservative versus the radical surgical management of acute and subacute pelvic infection. The former volume was to be strongly criticized for its obvious lack of conviction in this connection. In general the book is amazingly consistent, considering its compilation by diversified authors. No doubt the open critical analysis of each in relation to the work of the others contributes to this evenness. The book is sound, authoritative, simple and consistently helpful in spite of minor discrepancies.

Health In Middle Life. By Ethel Browning, M.D. Needs of To-Day Series No. 21, edited by W. E. Boardman. Cloth. Price, 3s. 6d. Pp. 249. London: Rich & Cowan, Ltd., 1938.

As more and more human beings survive middle age, the number of books of advice for people in this period increases. The reason is, of course, that the transition period is attended by many symptoms of a special type and that the average person has not been suitably informed as to the normal character of the changes that occur. This book, written by a British woman physician, opens with a discussion of the effects of middle age, particularly on the glands and on resistance to disease. It discusses the physical character of the man and woman of 40; then the transition period, and next the program to be followed after the transition period. It is a sane, dependable book of advice.

The British Encyclopaedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D. Volume IX: Mumps to Pneumothorax, Spontaneous. Cloth. Price, $12. Pp. 752, with 127 illustrations, including 10 plates. London & Toronto: Butterworth & Co. (Publishers), Ltd., 1938.

In this volume articles of special interest are concerned with the usual topics that would fall in the alphabetical classifications, but there are other special articles on such topics as professional negligence, edema (because the British spell it oedema), pain, paralysis, disputed paternity, the pituitary gland and pneumonia. Peptic ulcer is discussed by Dr. Thomas Hunt, edema by Jonathan C. Meakins of McGill University, thus far apparently the only Canadian to be selected as a contributor. This volume is well up to the standard of the previous items in this system of medical practice.

Medical Occupations Available to Boys When They Grow Up. By Leo M. Klinefelter, B.S., M.A. Cloth. Price, $2. Pp. 287, with 68 illustrations. New York: E. P. Dutton & Company, Inc., 1938.

The young man who is interested in learning some of the various ways in which medicine has extended its scope and something about the innumerable opportunities which now exist in fields closely associated with the practice of medicine will find in this guide book the necessary information. The author discusses the route by which one enters the practice of medicine and then has individual chapters dealing with the various technical specialties such as physical therapy, the clinical laboratory, and the x-rays; also chapters on dentistry, nursing, optometry, pharmacy and veterinary medicine. The book is written in the form of a conversation between a boy and a doctor. It is nicely illustrated and should be a most useful work for any boy finishing high school and ready to choose an occupation in the medical field.

Rheumatism. By Bertam S. Nissé, M.D., M.R.C.P., Hon. Physician, British Red Cross Clinic for Rheumatism, Peto Place, London. Cloth. Price, 5s Pp. 168. London: John Bale Medical Publications, Ltd., 1938.

This little book is a simple attempt to describe briefly the differential diagnosis and principal aspects of treatment of so-called rheumatism, including rheumatic fever, fibrositis, arthritis and gout. There is possibly some oversimplification in presentation, and the list of useful methods of treatment, especially for rheumatoid arthritis, would require careful selection for the individual patient. The general practitioner whose knowledge of these diseases is extremely fragmentary would find this volume helpful, but it can scarcely be considered comparable to some of the other more complete and more scientific recent books on or reviews of the subject.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Revocation of License for Procuring Abortions.—The medical practice act of New York authorizes the board of regents of the University of the State of New York to revoke the license of any physician who undertakes or engages "in any manner or by any ways or means whatsoever to procure or to perform any criminal abortion." By authority of this act the board of regents revoked the license of the petitioner, a physician, whereupon he appealed to the supreme court of New York, appellate division, third department.

The evidence presented before the board of regents, said the supreme court, showed that three female special investigators of the state department of education visited the petitioner's office on separate occasions and that on the occasion of each visit the petitioner made a vaginal examination of the investigator, advised that a condition of pregnancy existed, stated that he was willing to perform an abortion and fixed a date for the performance of it. The evidence further showed that he charged a fee of $5 for each examination and agreed to perform the abortion in each case for a fee of $100 and an additional $10 for the administration of the anesthetic. In the opinion of the court, the board of regents was justified in finding that the act in question had been violated. Accordingly, the court affirmed the action of the board of regents in revoking the petitioner's license.—*Kahn v. Board of Regents of University of State of New York (N. Y.), 4 N. Y. S. (2d) 233.*

Malpractice: Removal of Uvula and Soft Palate During Tonsillectomy.—The plaintiff, a minor, by his guardian ad litem sued the defendant for malpractice, alleging that during a tonsillectomy performed on him by the defendant the uvula and a portion of the soft palate were removed and the anterior and posterior pillars of the throat were injured. At the conclusion of the plaintiff's testimony, the trial court directed a verdict in favor of the defendant and the plaintiff appealed to the district court of appeal, second district, division 1, California.

The physician contended that the trial court properly directed a verdict in his favor because there was no medical testimony

adduced at the trial with respect to the propriety of his conduct In this case, said the district court, the evidence revealed a situation which clearly takes it out of that class of cases in connection with which expert testimony is indispensable The court then quoted from *Evans v Roberts*, 172 Iowa 653, 154 N W 923, as follows

> While it may be true that, had the operation upon the adenoids been unsuccessful and disappointing, no inference of negligence or want of skill would arise therefrom, it does not follow that this rule applies with the same force to an injury done by him to sound and undiseased parts of the plaintiff's person, which he was not called upon to treat and did not pretend to treat If a surgeon, undertaking to remove a tumor from a person's scalp, lets his knife slip and cuts off his patient's ear, or if he undertakes to stitch a wound on the patient's cheek, and by an awkward move thrusts his needle into the patient's eye, or if a dentist in his haste, leaves a decayed tooth in the jaw of his patient and removes one which is perfectly sound and serviceable, the charitable presumptions which ordinarily protect the practitioner against legal blame where his treatment is unsuccessful, are not here available "It is a matter of common knowledge and observation that such things do not ordinarily attend the service of one possessing ordinary skill and experience in the delicate work of surgery It does not need scientific knowledge or training to understand that, ordinarily speaking, such results are unnecessary and are not to be anticipated, if reasonable care be exercised by the operator"

The court also quoted from *Ilse v Ryan*, 8 Calif (2d) 82, 64 P (2d) 409, as follows

> Where the thing is shown to be under the management of the defendant or his servants, and the accident is such as in the ordinary course of things does not happen if those who have the management use proper care, it affords reasonable evidence, in the absence of explanation by the defendant, that the accident arose from want of proper care

It would appear, continued the district court of appeal, to be a matter of common knowledge that the removal of a portion of the soft palate and of the uvula is no part of a tonsillectomy The location of the tonsils is a matter easily observable to anyone, and the location and function of the uvula and soft palate are matters of common knowledge and of which a court can take judicial notice Therefore there was evidence in the record, at the time the motion for a directed verdict was granted, sufficient to support a verdict for the plaintiff had such verdict been returned The trial court, therefore, erred in directing the verdict, the jury should have been permitted to determine the matter of the defendant's negligence The judgment in favor of the defendant was accordingly reversed and the cause was remanded.—*Thomsen v Burgeson (Calif) 79 P (2d) 136*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (*6 cents if one and 18 cents if three periodicals* are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Urine Extractives in Cancer. H. Sobotka and Edith Bloch, New York. —p. 50.
Occasional Neutralization of the Active Agent of Filtrable Fowl Tumors by Fluid Mediums from Tissue Cultures. R. J. Ludford, London, England.—p. 63.
Comparative Activity of Some Carcinogenic Hydrocarbons. J. M. Twort and C. C. Twort, Manchester, England.—p. 80.
Relation of Nursing to the Extrachromosomal Theory of Breast Cancer in Mice. J. J. Bittner, Bar Harbor, Maine.—p. 90.
Note on Production of Sarcomas in Hamsters by 3: 4-Benzpyrene. W. E. Gye and L. Foulds, London, England.—p. 108.

Silicosis and Carcinoma of Lung.—Klotz reviews fifty cases of silicosis observed from 1925 to 1936 in the department of pathology and bacteriology of the University of Toronto. Twenty-five of these are from the necropsy files of the department, while in twenty-five the material was submitted by the department of health of Ontario for examination. Among these fifty cases, nine instances of carcinoma of various organs were found. This figure may possibly be too low, as the material submitted by the department of health consisted in most cases of only the thoracic organs. Four of the nine tumors were primarily bronchogenic. In 4,500 necropsies performed on patients dying in the Toronto General Hospital, 808 carcinomas of all organs were found. Of these, fifty-three were primarily bronchogenic. Both these figures are considerably lower than those of the first group. The average age incidence of those showing primary lung cancers in this larger series was 52 years and nearly all were laborers. Nine had given their occupation as miners, three as metal workers and two each as laborers, gardeners, gas company employees, engineers and laundry men. Among those describing themselves as miners, only one showed evidence of silicosis. Fourteen can be considered to have pursued occupations necessitating the inhalation of air containing either dust or other foreign matter. Though it is not entirely accurate to compare a selected group of fifty cases with a control group numbering 4,500, a comparison of the figures suggests that the incidence of carcinoma of the lung in silicosis may greatly exceed that among the population at large. The symptoms exhibited by the four patients with carcinoma of the lung found in the fifty cases of silicosis were not atypical for carcinoma of the lung. Dyspnea, cough, substernal pain, hemoptysis and loss of weight and strength were the prominent complaints. The duration of symptoms varied from three weeks to four years, with an average of twenty-five months. In case 4 the respiratory complaints were masked by those produced by metastatic destruction of various bony structures. In cases 1 and 3 bloody pleural fluid was obtained on thoracocentesis. In no instance was an x-ray diagnosis made, though all the patients had been subjected to such an examination. The average age of these patients was 48 years and with one exception (five years) all had been exposed to silica for a period exceeding twenty years. In case 1, in which the exposure was only five years, the lungs showed the most advanced degree of fibrosis and on analysis yielded the highest percentage of silica (33.98 per cent). The remaining cases showed only a minimal or slight degree of fibrosis attributable to the siliceous deposits. Case 2 alone presented evidence of tuberculosis and here the infective process had taken the form of a tuberculous bronchopneumonia. All the tumors were hilar in position, arising from the main bronchi on the left in three cases and on the right in one.

American Journal of Diseases of Children, Chicago

Experimental Poliomyelitis in Monkeys Lacking Olfactory Nerve Connections with Central Nervous System Produced by Intravenous Injection of Virus. J. A. Toomey, Cleveland.—p. 338.
*Distribution of Vitamin D in Body After Administration of Massive Doses. H. Vollmer, New York.—p. 343.

Extrasystoles in Children.—Lyon and Rauh detected extrasystoles in thirty-five of 782 children attending children's cardiac disease clinics, in three of 5,114 newborn infants, in forty of 1,782 school children selected by the physicians of the schools from a school population of about 85,000 as having some cardiac abnormality, and in seven of 709 children in a single elementary school. Of 2,672 children with normal hearts, extrasystoles occurred in fifty-nine (2.2 per cent); of 468 patients with cardiac lesions the irregularity was observed in twenty (4.3 per cent). In some instances rheumatic fever, diphtheria, congenital heart disease or emotional or nervous instability seemed to be a predisposing cause of the condition, but usually no evident cause of the extrasystoles could be determined. According to the electrocardiograms of twenty-two children, the extrasystoles were ventricular in origin in sixteen, nodal in three and auricular in three. In only one patient was the origin multifocal. In a series of forty-two patients who were observed for periods of from one month to ten years the extrasystoles occurred at only one examination in thirteen instances and for from one to five months in fourteen others, from six to eleven months in four, from twelve to twenty-three months in six and more than two years in the remaining five. There was no evidence that the presence of extrasystoles, by themselves, either caused any impairment of cardiac function or retarded the growth and development of the child.

Parental Serum Against Contagion.—Barenberg and his associates used parental blood serum regularly in an active pediatric ward as a prophylactic measure against measles, diphtheria and scarlet fever. Each child admitted to the medical pediatric ward received from 20 to 30 cc. of parental blood serum. The serum was readily absorbed without any untoward effects. The surgical ward served as a control. The use of parental serum maintained a constantly open ward free from outbreaks of contagious disease, preventing the spread of these disorders among already sick children. This prophylactic measure also decreased the number of hospital days in the medical pediatric ward.

Distribution of Vitamin D in Body.—Vollmer determined the vitamin D content of the organs of a child who died of tuberculous meningitis and miliary tuberculosis. Three and a half days before he died the child was given 600,000 U. S. P. units of vitamin D orally. At this time he was still in a condition which probably allowed the absorption of most of the vitamin. Most of the vitamin was stored in the skin, liver and brain. The kidney contained less vitamin. No appreciable amounts of the vitamin were found in the lungs, spleen or bones.

Normal Menstrual Irregularity.—Some 20,000 calendar records of menstrual cycles from about 1,500 women and girls, as given in twelve different studies, have been assembled, corrected and analyzed by Arey. The commonest length of 8,462 cycles (furnished by 585 persons) is twenty-eight days both for puberal girls and for adult women. The average length of all cycles is 33.9 days for girls and 28.4 days for women. The commonest length of 17,652 cycles (the grand mode of the individual modes of 1,265 persons) is divided between thirty and thirty-one days for puberal girls and is twenty-seven days for adult women. The mean length of cycle, based on individual averages, is 33.6 days for girls and 29.5 days for women. The maximal departures of individuals from their means extends from one to sixty-nine days in adults and from six to 211 days in puberal girls. In several hundred adults more than 21 years old, a fluctuation of about ± 2.5 days with respect to the mean expresses the limits of variability which contain two thirds of all cycles. Expressed differently, an average adult woman must expect one third of all her cycles to depart more than two days from her mean cycle length. The amount of variability shown by adults is greater than is ordinarily credited. Cycles ranging from two or three weeks to seven or more weeks appear in all of the groups (17 to 49 years) from which data have been collected. In the records of more than 500 women, 27 per cent never showed their own means during the observation period, which averaged eleven cycles. Only 20 per cent experienced their own mean in at least one third of their recorded cycles. The adults, reported in detail by eleven investigators, represent all ages from late adolescence to approaching menopause. They include American, Canadian, British, German and Hungarian subjects and various grades of society. In no instance did perfect menstrual regularity appear over any significant period of time; this is all the more noteworthy since many individuals had previously declared themselves to be the acme of invariability. It seems improbable that menstrual regularity, in any true sense of the word, ever will be encountered over significant periods of time. Certainly, not the slightest evidence pointing toward perfect regularity has so far been produced for even a single exceptional individual. Should such a person be found at some future time, she will constitute a true medical curiosity. Studies on the monkey and chimpanzee disclose menstrual irregularity comparable to that of the human being.

Retinal Examinations.—Mussey and Mundell point out that the weight of evidence indicates that acute late toxemia of pregnancy presents a hypertensive syndrome, characterized by generalized spasm of the smaller arteries. The degree of the spasm appears to parallel the height and duration of the blood pressure and the severity of the toxemia. Examination of the arterioles of the retina reveals changes which apparently manifest the degree of angiospasm throughout the body. In addition to hypertension and other symptoms, the presence and persistence of noticeable retinal vascular spasm is a guide in the management of late toxemia. This often indicates the need of avoiding further generalized and, perhaps, permanent vascular damage by terminating pregnancy when the condition of the patient permits. On the contrary, retinal changes of comparatively mild degree, or their absence, may indicate that pregnancy may be allowed to continue in the hope of obtaining a living infant without unduly jeopardizing the health and life of the mother.

Insulin Treatment of Dysmenorrhea.—Schrick gave regular insulin for from two to three months to ten college students from 16 to 29 years of age with dysmenorrhea. The insulin was given for from three to five days before each menstrual period. The menstrual periods of these women were regular and normal in all respects except for the association of pain of varying degrees of severity. Eight of the ten patients were benefited subjectively while under treatment, and three have had several menstrual periods free from pain without the use of insulin. The author has succeeded in relieving the cramplike pains of dysmenorrhea with a single injection of from 5 to 7 units of regular insulin given during the attack of dysmenorrhea with a supply of carbohydrate to counteract the antidiabetogenic effect of the insulin. This corroborates Altschul's observations. At present the author believes that insulin therapy in functional dysmenorrhea is successful because of its effect on the ovaries. The insulin treatment of this common complaint appears of value, but the subject needs further investigation.

Pituitary Fibrosis with Myxedema.—Castleman and Hertz cite a case of pluriglandular insufficiency without cachexia, clinically believed to be a case of myxedema. Except for the absence of cachexia, all the postmortem observations (fibrosis of the anterior lobe of the pituitary and atrophy of the thyroid, parathyroid, adrenal, ovary and uterus) are characteristic of Simmonds' disease. Pathologic and experimental evidence is presented which establishes primary disease of the anterior lobe of the pituitary in the pathogenesis. It is important to recognize that chronic pituitary insufficiency may exist.

Such a condition should be suspected in all cases of typical myxedema or in cases of myxedema in which earmarks of other endocrine deficiencies are present A negative thyrotropic assay of blood or urine in the untreated state of myxedema should suggest a primary deficiency of the pituitary

Testosterone for Treatment of the Eunuchoid State.—Thompson states that the greatest success with testosterone has been obtained in eunuchoid patients who have either failed to attain normal sexual development or who have been castrated by accident or surgical necessity The optimal dosage for a eunuchoid adult is approximately from 50 to 75 mg of testosterone propionate weekly, divided in two or three doses After a preliminary saturation with the compound the maintenance dose may be lowered Some patients develop a tolerance to the drug, so that later the maintenance dose has to be raised The patients are instructed to make the injections and they adjust the dosage to their needs Beneficial effects are observed from two to ten days after the injections are begun Excessive doses have produced priapism, an increase in body weight and a generalized puffy edema, acne of the face and trunk and precordial pain The latter symptom was so pronounced in one patient that the treatment had to be abandoned No other untoward results have been reported, but more time must pass in order to evaluate the results and the dangers of the treatment The drug is an effective therapeutic agent the clinical application of which deserves further study It may prove to be an indispensable natural form of therapy in cases of primary deficiency of the testes In other disorders having a psychic or constitutional origin, in which the testes are either secondarily or only apparently involved, the results may be harmful or ineffective This drug is now being sold in many drug stores, at which it can be purchased without a prescription At present the cost of this material and the lack of public knowledge of its action temporarily serve to prevent its unsuitable exploitation New and cheaper methods for its synthesis will probably be developed and this with the public's knowledge of its psychic, emotional and physical effects may bring about the necessity for controlling its sale The principles of therapy with testosterone are not sufficiently well established to recommend its use by the physician in general practice For a time, at least, it should continue to be studied in the clinic having the guidance of physicians who have had experimental and clinical experience with the endocrine glands and the advice of a psychiatrist, whose aid may be needed to solve the many psychic problems which confront these patients

Classification and Treatment of Obesity.—Fancher classifies obesity as exogenous, endogenous or mixed Insufficient function of the thyroid, pituitary and ovaries may cause obesity Hyperinsulinism is also a cause of overweight Diets based on ideal and not actual weight are valuable People are fully conscious of the value of a trim figure, though they may desire it more from the standpoint of beauty rather than from the standpoint of comfort and health Men are more lax than women in their attention to girth control and yet, as the chief wage earners, they should be the ones most vitally interested in this life-lengthening factor There is just as much adipose tissue stored within the body around the vital organs as there is under the skin Frequently a man will consult his physician for shortness of breath and a choking sensation on exertion or after a full meal, when the trouble is not primarily cardiac in origin but due to an excessive accumulation of adipose tissue about the heart and lungs and within the abdomen A definite reduction in weight brings about a prompt and refreshing relief from the dyspnea and choking

Cholecystectomy.—Hawkins enters a plea for a more or less routine procedure for cholecystectomy by downward dissection He states that this procedure may be slower and, if the cystic artery is not previously clamped, more bloody, but he feels that these objections are negligible if such a procedure will lessen the number of inadvertent injuries to the common and hepatic ducts After the abdomen is opened and the gallbladder is brought into the field, the liver may be manually rotated or the falciform ligament clamped and used as a retractor to tip the under surface of the liver to a more unobstructed view The fundus of the gallbladder is grasped with rubber covered forceps and traction is applied upward An elliptical incision is made about the grasping forceps through the peritoneal covering of the gallbladder With small forceps the peritoneum is grasped and held by an assistant The initial incision is continued down the inferior surface of the gallbladder and on to the cystic duct Blunt dissection with small forceps is continued to free the gallbladder from the liver, and any troublesome bleeding points are cut and clamped Gauze dissection is not used at any time As the dissection proceeds downward, another rubber covered forceps may grasp the gallbladder lower to bring the cystic duct more directly in the operative field The cystic artery should be ligated separately and for as long as possible so that

its ligated end may be finally closed over with peritoneum. When the junction of the cystic duct with the common duct is clear and distinct the cystic duct is doubly clamped, severed with a cautery and doubly ligated with chromic ligature. Stones may be palpated or the common duct explored at this time, a complete change of abdominal moist packs being inserted as a quarantine. If there is no jaundice present, the common duct is of normal size, no stones are palpable and aspiration reveals clear light colored bile further exploration is not necessary. The peritoneal flap resected from the gallbladder and cystic duct is sutured continuously over the stump of the duct and the ligated cystic artery along the bed of the liver, so that complete peritonealization of the gallbladder area is obtained. The abdomen in the absence of common duct drainage is closed without drainage, the only exception being when the gallbladder has been torn inadvertently. In draining the common duct there are several pitfalls to be avoided: the incision in the duct need not be larger than to permit the insertion of a folded T drain or the removal of stones. Meticulous attention should be given to the condition of the rubber T tube. It should be thoroughly tested and inspected before insertion to ascertain that the rubber is vital and that no leaks are present.

Compatible Blood for Transfusion.—Cameron outlines the technic used at Trinity Hospital for the determination of the compatibility of blood for transfusion. The technic is a modification of the Landsteiner test tube method. Preliminary typing is carried out in order to reduce the number of compatibility tube tests necessary for selecting a donor. The typing and cross matching are not directly involved in this final determination, which concerns only the reactions seen in the test tubes. Ten test tubes are arranged in numerical order in a rack. Into the first five tubes is placed 0.1 cc. of a 5 per cent saline suspension of the donor's erythrocytes. To tubes 1, 2 and 3 is added the recipient's serum in the following amounts respectively: 0.1, 0.2 and 0.4 cc. and 0.4 cc. of the donor's serum is added to tube 4. Into tubes 6, 7, 8, 9 and 10 is placed 0.1 cc. of a 5 per cent saline suspension of the recipient's erythrocytes. To tubes 6, 7 and 8 is added the donor's serum in the following amounts, respectively: 0.1, 0.2 and 0.4 cc. and 0.4 cc. of the recipient's serum is added to tube 9. Physiologic solution of sodium chloride is added to the ten tubes in amounts sufficient to make the content of each equal to 1 cc. In tubes 1, 2, 3, 6, 7 and 8 occur the cross reactions between the serum of both the donor and the recipient in three different dilutions and their erythrocytes. In tubes 4, 5, 9 and 10 occur control reactions between serum and erythrocytes of the same origin in saline solution and between the saline solution and the erythrocytes alone of both the donor and the recipient. After preparation, the tube mixtures are allowed to stand for one and one-half hours, as delayed reactions are not uncommon. In approximately 4 per cent of tests between bloods of the same group incompatibility is found which is usually due to agglutination but occasionally to hemolysis. If the macroscopic evidence of agglutination is at all doubtful a microscopic examination is carried out. The author states that this test tube method has been relied on at Trinity Hospital for more than 1,200 transfusions performed during the last six years. No reactions of incompatibility have occurred. The extra time and effort which the test requires is fully justified by its incomparable superiority as a laboratory procedure on which life depends.

*Vitamin B Deficiency and Nervous Diseases. F. H. Lewy, Philadelphia. —p. 174.

Vitamin B Deficiency and Nervous Diseases.—The epitome that Lewy presents on the relation of nervous disease and vitamin B deficiency is as follows: 1. Changes in the electrical irritability of the peripheral motor nerves apparently are the first clinical signs of a B avitaminosis. 2. At the same time the pyruvic acid increases in the blood and urine, indicating a gradual vitamin B deficiency. 3. Simultaneously also the ketone bodies increase in the blood and urine, indicating a gradual exhaustion of glycogen. 4. The neuropathy can be cured by the administration of vitamin B as well as by the reconstruction of the glycogen stocks through the administration of carbohydrates supplemented by insulin. 5. The liver is the greatest storehouse of vitamin B and of glycogen. 6. The liver loses four fifths of its vitamin B stock in the first week of a diet deficient in vitamin B. 7. The liver proves to be severely damaged pathologically in such diseases in which a neuropathy or myelopathy is present. 8. After exhaustion of the "mobile" liver vitamin, its "fixed" depot in the nervous system begins to decrease. At this moment the nervous symptoms appear. 9. Clinical, pathologic and experimental experience suggests strongly that in diseases of the spinal cord, of the basal ganglions and of the hemispheres a vitamin B deficiency may also play a part. Considering these facts, it seems difficult to overlook the central position of the liver in the mechanism of the occurrence of certain nervous diseases. The liver harbors and eventually loses not only vitamin B but also A, C, D and others. For example, in lead poisoning one finds—in addition to the nervous signs which alone attract one's attention—paradontoses and final loss of the teeth due to an A avitaminosis, a tendency to hemorrhages producing the severe pains in the calves known from vitamin C deficiency and eventually an increased fragility of the bones. The neuropathies and myelopathies usually do not appear as accompaniments of the basic disease but after an interval of weeks, months and even years, as in the postencephalitic parkinsonism. They represent the metanosic type of disease, in other words an after-disease. The problem of the origin of nervous diseases should not be oversimplified by creating a new collection box labeled "B avitaminosis."

Treatment of Arthritis with Sulfanilamide.—Coggeshall and Bauer treated fourteen cases of proved and four of probable gonorrheal arthritis, two cases of gonorrhea and two cases of proved and two of probable gonococcic prostatitis with sulfanilamide. Sulfanilamide administered in large doses for two or more weeks appeared to be a specific chemotherapeutic agent for certain strains of gonococci because: 1. Infected synovial fluids can be sterilized in from forty-eight to seventy-two hours after the institution of therapy. 2. In seventeen of the eighteen cases in which a proved genito-urinary focus existed, no gonococci were found after the third day of treatment. These cases remained clinically cured during the follow-up periods. 3. The gonococcus complement fixation test failed to become positive in three cases of gonorrheal arthritis in association with infected synovial fluids. In nine of the remaining eighteen cases the complement fixation test became negative. 4. Nine of the proved and two of the probable cases of gonorrheal arthritis showed striking clinical improvement in from forty-eight to seventy-two hours after therapy was begun. 5. The end results in the fourteen proved and the four probable cases of gonorrheal arthritis were more satisfactory and took place in shorter periods of time than occurs with other forms of therapy. The toxic manifestations resulting from the administration of large doses of

sulfanilamide do not represent serious complications (except for the hematologic changes) and are corrected promptly when the drug is discontinued. A slow, progressive, subclinical hemolytic anemia occurred in thirteen of the twenty-eight cases. Leukopenia was observed in two cases. The erythrocyte sedimentation rates fell rapidly in the cases of gonorrheal arthritis showing striking and immediate relief.

Renal Function in Hyperthyroidism.—Bartels states that hyperthyroidism, no matter how severe, does not affect or alter renal function as determined by the urea clearance test. In only six of twenty-three cases was the urea clearance test below the range of normal. This was of a minor degree; since five of the six occurred in patients more than 50 years of age, this change can be explained as some minor vascular renal disturbance common to patients of this age. No relationship was found between the urea clearance and the type of hyperthyroidism (either exophthalmic or adenomatous goiter), duration of disease, loss of weight, level of the basal metabolic rate or severity of the disease as indicated by the type of operative procedure employed. Patients with hyperthyroidism in the absence of cardiac failure or preexisting nephritis tolerate an abundance of fluid intravenously. The results also probably disprove the presence of a hepatic-renal syndrome, for, in spite of severe degrees of changes in hepatic function which have been found in cases studied at the Lahey Clinic, the kidney has escaped alteration in its function.

Thyroid Therapy in Epilepsy.—In order to determine the primary effect on seizures and the secondary effects on basal metabolism, blood sugar, weight, tremor, blood pressure or pulse rate, Doolittle gave at first 0.032 Gm. and then 0.065 Gm. of thyroid extract to forty-seven patients with epilepsy. During administration the number of attacks increased in 53 per cent of the patients, decreased in 36 per cent and did not change in 10 per cent. In twenty-one patients the number of seizures increased for the three months following the withdrawal of the drug, and thirteen of these returned to the pretreatment level nine months after withdrawal. An increase in the basal metabolic rate was observed in 91 per cent of the patients, an increase in blood sugar in 63 per cent, a loss of weight in 64 per cent, only 36 per cent showed tremor and 93 per cent showed a decrease in blood pressure; 84 per cent of the patients in whom a disproportionate fall of diastolic pressure was observed had increased attacks and 65 per cent showed increase in pulse rate. There seemed to be no relationship between the rapidity of the pulse and the number of attacks. About half of the patients were receiving phenobarbital. This sedation seemed to have no influence on the frequency of attacks under thyroid extract. The author feels that an improvement with respect to the number of attacks while under thyroid treatment was evident in from 35 to 40 per cent of the patients. From 60 to 65 per cent appeared to be made worse by the drug. Approximately the same percentages existed in correlating seizures with changes in basal metabolic rate, blood sugar, weight, blood pressure or pulse rate, and with incidence of tremor. A patient subject to unstable diastolic blood pressure or a diastolic blood pressure easily decreased by thyroid extract should not be given this drug.

Psychoses Among Negroes and White Persons in Prisons.—Karlan investigated all the first admissions to the Dannemora State Hospital from the New York State prisons from June 30, 1928, to June 30, 1938. These included 687 white persons and 188 Negroes. During these ten years there were 25,538 white and 5,494 Negro commitments to the institutions of the New York State Department of Correction. From his observations the author concludes that the incidence of psychoses in the general population is higher in Negroes than in white people. In the New York State prisons, Negroes and white prisoners are in a similar cultural and economic environment. The incidence of functional psychoses among Negro inmates is about the same as that among white prisoners. Negroes have therefore no racial predisposition to mental disease. The high incidence of mental disease among them is probably due to cultural, social and economic causes. The incidence of psychoses among prison inmates is from five to ten times as high as that of the general population. This is mostly due to the inherent constitutional instability of the criminal group.

Influence of Pituitary in Thyroid Disease.—Two years ago the Thompsons and their collaborators reported that in about 50 per cent of patients showing various levels of thyroid function a temporary increase in basal metabolism could be produced by pituitary extracts containing the thyrotropic factor. They now extend and confirm these observations. Out of 123 courses of injections to 106 patients of all types, the basal metabolism was increased by 10 points or more in fifty-six instances. Considering only the initial series of injections, an increase was observed in fifty-one instances. The response was always temporary in spite of continued administration. The observations suggest that the maintenance of normal thyroid activity depends to some extent on factors outside the thyroid, among which the function of the anterior lobe of the pituitary plays an important part. They are consistent with the hypothesis that hypothyroidism may be of two types, primary and secondary. In the primary type the hypothyroidism is the result of loss of thyroid tissue by operation, atrophy or infection. It is seen in patients with marked myxedema, who show characteristic and complete improvement with the administration of desiccated thyroid. The secondary type is caused by lack of adequate stimulation of the thyroid, notably by the anterior lobe of the pituitary, and is seen in patients suffering from hypofunction of this gland, in Simmonds' disease and in certain pituitary tumors associated with a low basal metabolism. Hyperthyroidism, like hypothyroidism, may be secondary to a corresponding state in the anterior lobe of the pituitary. In twelve patients with myxedema and basal metabolism varying from minus 31 to 47 per cent, no increase in basal metabolism was produced by the administration of anterior pituitary extracts containing the thyrotropic factor. In about half of ninety-four other patients showing various levels of thyroid function from moderate hypothyroidism to marked hyperthyroidism, increases in basal metabolism of from 10 to 53 points were produced. The magnitude of the response appeared to be related to the level of metabolism before treatment was started, being greatest in the patients with mild hypothyroidism and least in the patients with hyperthyroidism. In nineteen patients with basal metabolic rates of from minus 29 to plus 8 per cent the rate was raised as high as 36 per cent above normal, and various manifestations of hyperthyroidism were produced: tachycardia, nervousness, tremor, emotional disturbances, weakness, ease of fatigue, loss of weight, increase in perspiration and increase in the size of the thyroid.

Auricular Fibrillation and the Thyroid. E. G. Slesinger.—p. 65.

Treatment of Sterility.—Between August 1937 and June 1938, sixty-two women who attended an outpatient department for sterility were observed and treated by White. Forty-seven of them complained of absolute sterility, nine of one child sterility, one that she could not become pregnant with a second husband (although she had had four children by the first husband) and five that they had had one or more miscarriages. By September 1938, twenty-two patients were pregnant—that is, 47.8 per cent of those in whom pregnancy was possible, since sixteen patients either had nonpatent fallopian tubes or their husbands were known to be sterile. Of the twenty-two who became pregnant seven miscarried, but two are now pregnant again. Of the remaining twenty-four women who have not yet become pregnant it is assumed that in 21 per cent the husband is sterile, judging from the result of the thirty-nine whose semen was examined; but this still leaves a number of women in whom so far pregnancy has not occurred though study of both partners has been favorable. Iodized poppyseed oil by itself has a therapeutic value in that it opens up the fallopian tubes. It would seem to be of greater use than air insufflation, because the latter ceases to distend as soon as the pressure is reduced. Forty patients injected with the oil received no glandular therapy and thirteen became pregnant. There was tubal occlusion or sterility of the husband in fourteen of these forty cases, so that a 50 per cent success can be attributed to the injection of the oil alone. It is known that the failure of many patients to conceive is due to failure of ovulation, and it is claimed that ovulation is more likely to occur after suitable administration of endocrine products. Dihydroxyestrin benzoate given in two weekly doses of 20,000 international benzoate units in the two weeks directly following the menstrual period, or as a larger dose of 50,000 international benzoate units about the twelfth day of the menstrual cycle, appears to have had some value. In cases in which the uterus is undersized, nidation of the fertilized ovum is more likely to occur if further development is brought about by more regular and prolonged glandular therapy. Failure of the fertilized ovum to embed is one of the causes of sterility. Investigation on the pregnandiol (excretion product derived from the corpus luteum) content in the urine at the time of ovulation in sterile patients is being undertaken. Insufficiency of the latter substance may be dependent on an insufficiency or an unbalanced output of anterior pituitary hormones. Sterility may depend on an incorrect balance between the follicular and luteinizing factors of the anterior pituitary gland. It is hoped that in time one may be able to isolate the hormones from the gonadotropic substance present in the urine of pregnant women and inject them into sterile women. Thyroid insufficiency (in both parties) may account for sterility, since Lawrence and Rowe (1928) have shown that 39 per cent of a series of patients with some degree of thyroid insufficiency were sterile. The treatment of as many as possible of the existing causes of sterility at the same time raises the fertility level and renders pregnancy more likely.

Prophylaxis with Sulfanilamide Compounds.—Hoare records experimental data which appear to justify clinical trial of sulfanilamide derivatives in the prophylaxis of hemolytic streptococcus infections. Prophylactic immunization may be indicated under certain circumstances in maternity work, in association with tonsillectomy in a patient known to be a carrier of hemolytic streptococci and possibly to avert a dangerous extension of infection when operating on the mastoid or other acutely infected tissues. The possibility of prophylactic immunization in obstetric practice does not in the least warrant any abandonment of antiseptic or aseptic technic in the conduct of labor. The author found that mice can be protected against an infection by hemolytic streptococci (from 100 to 1,000 minimal lethal doses intraperitoneally) by the subcutaneous injection of a single dose of sulfapyridine within the previous forty-eight hours. With sulfanilamide a single subcutaneous prophylactic injection has but little effect, owing to its greater solubility, but good protection is obtained if, in addition to the prophylactic dose, the drug is given orally twice a day for three days after the infection by hemolytic streptococci. Repeated administration is necessary after infection if sulfapyridine is given orally. A high bactericidal power was demonstrated in the blood of uninfected patients during the puerperium, three under treatment with sulfapyridine and six with sulfanilamide. The suggested dosage is 1 Gm. of sulfanilamide or of sulfapyridine orally three times a day, beginning as soon as labor starts and continuing for three or four days.

Cutaneous Diseases in the Winter.—Haldin-Davis considers the cutaneous diseases of winter under three divisions: the effects produced by cold alone, the results of exposure to conditions of cold and damp and the effects of cold on pre-existing dermatoses. Frostbite is due to the action of cold, especially of dry cold, and its effects are often increased by the wind. Three degrees of severity are described: hyperemia and damage to the cutaneous capillaries, edema of the dermis and an infiltration of leukocytes, and complete thrombosis of the blood vessels of the subcutaneous tissue and necrosis through the whole depth of the skin. Foremost among the results of exposure to cold and damp are trench foot, chilblains and erythrocyanosis crurum puellarum. Most preexisting cutaneous troubles are aggravated by exposure to cold. This is noticeably true of ichthyosis, psoriasis, most forms of eczema and allergic conditions, and also lupus erythematosus. On the other hand, acne vulgaris tends to improve during the cold weather.

Spontaneous Hemoperitoneum in Men.—Mondor and Olivier say that for a long time spontaneous hemoperitoneum was regarded as peculiar to women in that it is usually traceable to extra-uterine pregnancy. Spontaneous hemoperitoneum in men was regarded as extremely rare but the authors show that it does not deserve this reputation of extreme rarity. A review of the literature revealed more than 400 cases of spontaneous hemoperitoneum. This number includes those observed in men and those of nongenital origin in women. Classification of these according to their causes reveals that 251 were of splenic origin (rupture of the spleen in malaria, typhoid, recurrent fever, leukemia, tumor, infarct and so on); 122 were of vascular origin (rupture of aneurysm of the splenic artery, rupture of the hepatic artery, of the abdominal aorta, of the vessels of the stomach, of the splenic vein, of the superior mesenteric artery and so on); forty-four were of hepatic origin (rupture of the liver or of a hepatic tumor or aneurysm) and fifteen cases were of obscure origin. The authors show that the clinical diagnosis of spontaneous hemoperitoneum is not impossible if it is thought of. They discuss the symptomatology and the methods of examination that may prove helpful in detecting it but admit that in many instances the discovery of the hemoperitoneum is still a surgical surprise. In this event it is necessary to explore first the splenic region and, if this exploration proves negative, the liver and the other possible sites of the hemorrhage must be investigated. Favorable surgical results are possible, particularly if the blood comes from the spleen or from an artery of the stomach.

*Use of Sulfanilamide in Urinary Infection with Colon Bacilli. C. J. Gessler and A. Lippens.—p. 124.

Sulfanilamide in Urinary Infection with Colon Bacilli.—Gessler and Lippens report therapeutic experiences with paraminophenylsulfamide in thirty-eight cases of urinary infections with colon bacilli. The patients presented clinical symptoms, not merely colibacilluria. In nineteen of the patients the disorder was acute, in the others it was chronic. The authors give brief clinical histories of each of the patients. In all acute cases the oral administration of the paraminophenylsulfamide produced cure within several days. The fever and the disturbances of micturition often disappeared from the second day of the treatment, whereas the urine became normal again several days later. The authors recommend the administration of 3 Gm. a day during the first forty-eight hours and 2 Gm. daily thereafter for a period of from five to eight days. In one of the nineteen acute cases a relapse occurred which, however, could be readily counteracted by a new series of treatments with sulfanilamide. In some of the patients with chronic urinary infection the disorder had proved refractory to other therapeutic methods, but in only one of them did the urinary infection prove resistant to the sulfanilamide therapy. The dosage in the chronic cases is practically the same as in the acute cases; that is, the patients are given 3 Gm. for two days and then 2 Gm. daily until the urine becomes normal. After that the medication is continued for a few days with 1.5 Gm. In this connection the authors point out that some observers advise interruption of the treatment after two weeks so as to prevent the development of a resistance to the medicament in the micro-organism. Because the efficacy of the sulfanilamide seems to be improved by an alkaline milieu, the authors administer with each dose 0.5 Gm. of sodium bicarbonate; this is the more advisable because the sulfanilamide tends to produce acidosis. The patient

should not drink too much during the treatment, so that the concentration in the urine does not drop too low. The authors conclude that sulfanilamide is highly effective in urinary infections with colon bacilli.

47: 137-152 (Jan. 28) 1939

*Attempt to Treat Arterial Hypertension of Renal Origin by Surgical Vascularization of the Kidney (Nephro-Omentopexy). P. Abrami, M. Iselin and R. Wallich.—p. 137.
Treatment of Burns by Infra-Red Rays. J. Gautier.—p. 139.

Revascularization of Kidney in Arterial Hypertension.—Abrami and his associates point out that numerous surgical attempts have been proposed to cure or to improve progressive chronic arterial hypertension. This multiplicity of interventions suffices to show their slight value, whether the intervention is a unilateral or a bilateral section of the splanchnic nerves, a unilateral adrenalectomy, a renal decapsulation or an enervation of the renal and adrenal pedicles with or without ablation of the first and second lumbar aorticorenal ganglions. All these technics, whether employed alone or in combination, produce only temporary and inconstant improvements. After discussing factors that are probably responsible for the failure of these treatments, the authors cite investigators who have proved that renal ischemia plays an important part in the pathogenesis of certain forms of hypertension. This renal ischemia seems to be independent of nervous factors, for it may appear even after enervation of the kidney; that is, the vascular factor is the decisive one. To combat the renal ischemia efficiently, surgical interventions, different from those heretofore employed, seem necessary. A procedure which creates a new vascular plexus in the kidney appears to be the solution for this problem of renal ischemia. The authors point out that the revascularization of an ischemic organ has already been successfully carried out. In this connection they cite the work on the revascularization of the ischemic myocardium carried out by Beck in America and by O'Shaugnessy in England. Heymans and his collaborators in Ghent transferred the experiences made on the heart to the sphere of the kidney. They demonstrated on dogs that by an artificial revascularization, obtained by a renoperitoneal anastomosis, it is possible to counteract the hypertension that is brought on by renal ischemia. The authors resorted to this measure for the first time in two human subjects. They designate their intervention as nephro-omentopexy. They expose the kidney by a lateral transverse incision; they decapsulate it, open the peritoneum and draw a well vascularized portion of the omentum through a window in the posterior parietal peritoneum. They lightly scarify the antero-external surface of the kidney and suture the omentum to it. They report two cases in which they employed this procedure. They gained the impression that the operation had been made too late and that, in order to produce results, nephro-omentopexy must be performed on both sides. However, in spite of failure at the onset, the authors conclude that this method is not only possible in human subjects but easy to perform and not harmful.

*Employment of Venin of Bothrops Atrox as Hemostatic. C. J. Hanut.—p. 21.
Multiple Myeloma. J. R. Grosgurin.—p. 30.

Venin of Bothrops Atrox as Hemostatic.—Following a review of the literature on the use of venins for hemostatic purposes, Hanut describes his studies with a dry venin of Bothrops atrox and with an antibothropic serum prepared with the aid of the venin of Bothrops jararaca. On the basis of his studies he reaches the following conclusions: 1. The venin of Bothrops atrox can be used in hemophilic subjects either in dilute solutions or mixed with an appropriate dose of antibothropic serum. Under these conditions it is deprived of its coagulating toxicity and it does not produce secondary incoagulability. On the contrary, it preserves a slight coagulating action for at least six hours. It is to be recommended especially before a surgical operation on hemophilic subjects. 2. The venin of Bothrops atrox is useless and contraindicated in the majority of hemorrhagic disorders without disturbances of the coagulation, because it is either without effect on the time of bleeding or else it even prolongs it. 3. Because of the thrombinic action of the venin of Bothrops atrox in vitro, which transforms the fibrinogen into fibrin without interfering in the normal mechanism of coagulation, it appears that the employment of the venin of Bothrops atrox as a local hemostatic should be given serious consideration.

Senile Involution of Appendix and Sclerotic Atresia in Chronic Appendicitis. L. Sanguigno.—p. 47.
Benign Lymphocytic Meningitis: Case. G. Ceruti.—p. 57.
*Venous Septicemia. C. Cantieri.—p. 63.

Venous Septicemia.—According to Cantieri, venous septicemia is a clinical entity which includes not only subacute forms which have been heretofore described but also benign and acute forms. The condition is due to an early selective location of bacteria in the venous system. Phlebitis develops successively at different segments of the veins of the extremities or of the viscera in the course of recurrent attacks of fever and of a pulmonary disease with small foci of pneumonia or bronchopneumonia. The evolution of the condition depends on (1) the intensity of the general infection which causes septicemia, (2) the extension of the vascular lesion, (3) the segment of a vein which is involved (whether peripheral or visceral and superficial or deep) and (4) the intensity of the consequent circulatory disturbances. The condition is restricted to small septic foci and spreads by small foci. Mild forms involve predominantly the veins of the limbs and subside at resolution of phlebitis after two or three recurrences of moderate intensity. Subacute forms may show predominant pulmonary or vascular peripheral symptoms. They follow a long evolution and may be complicated by acute forms. Periphlebitis or thrombophlebitis in periarticular veins is grave. Acute forms are rapidly fatal from the first attack. The most important forms are those of the monoplegic, quadriplegic and phlegmatic types, as well as the type of pulmonary infarct which causes hemoptysis and those which develop with either bronchopneumonia or pleurisy or in the course of pulmonary tuberculosis. The author gives examples of each of the different types. The differential diagnosis of these forms is of importance, as subacute forms can derive benefit from an opportune surgical treatment.

*Treatment of Gonococcic Vulvovaginitis in Little Girls with Sulfanilamide. A. J. Aballí, J. G. Cabrera Calderín and J. M. Labourdette Scull.—p. 64.

Sulfanilamide in Treatment of Vulvovaginitis.—Aballí and his collaborators made a comparative study of the results of sulfanilamide and other different treatments on a group of thirty girls ranging in age from 3 to 9 years who were suffering from gonococcic vulvovaginitis. The infection was at about the same stage of acuteness in all cases. All the patients were hospitalized. Sixteen of the patients were given sulfanilamide orally in three daily fractional doses up to a total daily dose of from 0.6 to 1 Gm. for each 10 pounds (4.5 Kg.) of body weight. The drug was given in series of seven or eight consecutive days followed by periods of rest lasting from three to seven days. The course of treatment consisted of two series and in rare cases three series. No other treatment was given except in one case. The patient was given santonin for intestinal parasitism in the course of the treatment. Acute jaundice followed. Recovery was obtained in twelve of the sixteen cases in an average of twenty-five days. One patient had spontaneous regression six months after failure of the treatment, which failed in three cases. Fourteen patients were given one or several of the following treatments: vaginal antiseptic irrigations, local application of bactericidal substances including fuchsin, vaccines, pyretotherapy or injections of estrogenic substances. Four of the patients recovered in an average of ninety-six days. The treatment was of no benefit to the rest of the patients of the group. The author therefore concludes that sulfanilamide in the proper dosage is of value in the treatment of vulvovaginitis in little girls. The treatment is well tolerated. The administration of any other drug in the course of the treatment is contraindicated. The patients who are going to obtain satisfactory

results show a prompt favorable reaction, which consists in diminution of the clinical symptoms and rapid disappearance of the vaginal discharge. It is advisable to continue the treatment for at least one or two complete series regardless of early satisfactory results. Rest is a factor of importance. Some patients, in the proportion of one to four, do not respond to the treatment. If satisfactory results are not obtained in the course of the first, second or even the third series, the treatment should be discontinued.

Characteristic Syndrome of Infection with Influenza Bacilli.—Kleinschmidt directs attention to a characteristic syndrome of infection with influenza bacilli, which was first brought to his attention in 1930. The syndrome begins with laryngeal stenosis; then follows a suppurating pericarditis and pleuropneumonia. In one of the cases observed by the author and in two cases that were reported by Baumeyer a suppurating meningitis developed. These cases terminated in death. Recently the author observed the aforementioned syndrome in a boy aged 6½ years. In this case, however, the process remained localized; the suppurating meningitis, which is due to bacteremia, did not develop. The syndrome was restricted to laryngeal stenosis, bronchopneumonia, suppurating pericarditis and pleural empyema on the right side. This patient was cured. The author says that he described these cases not in the interest of rare casuistics but rather because the syndrome is characteristic and recurs in an analogous manner. It is caused by a pharyngeal infection with influenza bacilli, which apparently spreads by way of the mediastinum. Exact and systematic bacteriologic tests are essential in this disorder.

Increasing Activity of Gonadotropic Substance by Ascorbic Acid. B. Giędosz.—p. 63.

Influence of Insulin on Glycogen Formation.—Brentano says that it was recently observed that the capacity to produce glycogen from dextrose is impaired not only during pancreatic and starvation diabetes but also in all disorders that are accompanied by creatinuria. Thus it was proved that a metabolic disorder heretofore regarded as specific for diabetes mellitus is not always the result of an insulin deficiency. The author decided to investigate whether insulin is capable of improving this impairment in the glycogen formation, even if it is not directly traceable to insulin deficiency. He investigated the glycogen formation in the musculature and liver after rabbits had been starved for twenty-four hours and then had been given 10 Gm. of dextrose for each kilogram of body weight. This quantity of dextrose was divided in half, and in order to insure a better resorption the second half was given two hours after the first half. The dextrose was given either alone or in combination with insulin. The glycogen content was tested five hours after the administration. Summarizing, he says that if 0.5 unit of insulin is administered for each gram of dextrose the glycogen content of the musculature is approximately 38 per cent greater and that of the liver is 20 per cent smaller than if the dextrose is given alone. If the insulin dose is reduced, the difference between the glycogen content of musculature and liver is much less pronounced. If the quantity of insulin is reduced to 0.01 unit for each gram of dextrose, there is hardly any difference from the exclusive administration of dextrose. In the concentration in which the insulin still exerts an influence on the glycogen formation, it never increases but always decreases the glycogen storage in the liver.

Liver and Elimination of Vitamin A.—Thiele and Seedorf point out that studies on the elimination of vitamin A in the urine have demonstrated that the normal organism does not eliminate this vitamin in the urine and that the diseased organism does this only under certain conditions. After citing investigators who detected vitamin A in the urine of patients with cancer, tuberculosis, general infections, lobar pneumonia, renal disorders and particularly hepatic disturbances, the authors say that, in studies on the causes of the urinary elimination of vitamin A, liver and kidney have always been regarded as having an important part. It cannot be doubted that the liver is important in the vitamin A exchange, for in the healthy as well as in the diseased organism vitamin A is found chiefly in the liver. Although the results of some investigations have directed attention to the importance of the reticulo-endothelial system in the elimination of vitamin A, the authors decided to investigate, on clinical material, under what conditions the impaired liver causes the elimination of vitamin A in the urine and to what extent the elimination of vitamin A can be utilized diagnostically. In the search for a suitable test method they found that the Carr-Price reaction is the most reliable, provided sufficiently large quantities of urine are used. In single tests vitamin A often fails to appear in spite of the fact that there is occasional elimination. Surveying the results of their studies, the authors conclude that the elimination of vitamin A is not pathognomonic for hepatic disturbances as such, for it may occur even in the presence of an intact hepatic function. Thus conclusions regarding the condition of the liver cannot be drawn from the outcome of the vitamin A reaction in the urine. However, the authors point out that experimental studies on animals have directed attention to the reticulo-endothelial system and that their own clinical observations suggest that an impairment of the reticulo-endothelial system might be the cause of the elimination of vitamin A.

Rehberg's Functional Test of Kidneys.—Klurfeld directs attention to the functional test of the kidneys that was described by Rehberg in 1926. He reviews the filtration-reabsorption theory on which Rehberg based his functional test of the kidneys. According to this theory the glomeruli extract from the plasma by ultrafiltration a fluid which, with the exception of the plasma proteins, contains all substances in the same quantities as does the blood plasma. In the course of its passage through the tubules this preliminary urine undergoes essential changes which are the result of two functions of the cells of the tubules. 1. The cells of the tubules have an active resorptive capacity for substances that are vitally important for the organism; for instance, chlorides and dextrose. 2. Substances that are of less importance for the organism are diffused through the cells of the tubules. In Rehberg's functional test, creatinine is employed because it has the highest concentration index; that is, it is excreted by the kidneys in maximal quantities and apparently is not reabsorbed. The author shows that by determinations of the creatinine contents of the blood and urine and by measuring the quantity of urine it is possible to compute (1) the index of concentration, (2) the quantity of filtrate from the glomeruli and (3) the quantity of resorbent retained by the tubules. After discussing the technic of Rehberg's test, which is used for theoretical purposes, the author shows that for practical purposes the method can be somewhat simplified. The person whose

renal function is to be tested has to refrain from eating or drinking beginning with the evening of the day preceding the test. At 8 a. m. 2 Gm. of creatinine is given in 500 cc. of water. This comparatively large quantity of water is given in order to maintain an adequate diuresis. At 9 a. m. the bladder is evacuated either spontaneously or by catheterization and a specimen of blood is withdrawn. After another forty minutes has elapsed, the bladder is once more evacuated and blood is again withdrawn from the cubital vein. The quantity of urine is measured in order to determine the filtration per minute. After small quantities of potassium oxalate and of sodium fluorite have been added to both of the blood specimens, they are centrifuged and, of the quantities of plasma thus obtained, equal amounts are combined and mixed and then are examined for the creatinine, urea and sodium chloride content. The author is convinced that with Rehberg's functional test of the kidneys results can be obtained which cannot be realized by other means.

Vaccination of Nurses Against Diphtheria.—Plum says that in this vaccination at Blegdam Hospital the best method proved to be one subcutaneous injection of 1 cc. of purified anatoxin with the addition of 10 volumes per cent of aluminum hydroxide, containing from 35 to 50 precipitation units of anatoxin, followed four, five and six weeks after the injection by the application of five drops of purified anatoxin in each nostril, in all twenty-five precipitation units each time. A local reaction was absent in 8 per cent, slight or moderate in 66 per cent and marked in 26 per cent. A general reaction was absent in 64 per cent, slight or moderate in 20 per cent and marked in 16 per cent. The more antitoxin in the blood before vaccination, the more marked the local and general reactions. Of 603 not vaccinated student nurses, 57 per cent had no diphtheria antitoxin in the blood, 23 per cent had between 0.0005 and 0.10 unit per cubic centimeter and 20 per cent had 0.10 unit or more per cubic centimeter. The antitoxin content of the blood before vaccination was 0.10 unit or more per cubic centimeter in 12 per cent of 160 students; after vaccination the blood contained this amount or more in 91 per cent of the number and more than 1 unit per cubic centimeter in 58 per cent. In the six year period before vaccination was introduced eighty-four student nurses had diphtheria, with a total of 2,698 days of illness; sixteen cases were grave, one of these fatal. In the subsequent six year period, after vaccination, only eighteen cases of diphtheria occurred, with a total of 566 days of illness; four cases were grave but without noteworthy complications. The author considers the antitoxin titer a measure of immunity; in his opinion an antitoxin content in the blood of 0.1 unit per cubic centimeter probably protects against diphtheria.

Primary Serous Meningitis and Paralytic Poliomyelitis.—Lassen finds that endemic clinical paralytic poliomyelitis agrees with endemic primary serous meningitis in the apportionment as to age, sex and the different social classes and most of the symptoms and objective signs before and during hospitalization. While no certain differences between the two groups appear, the endemic cases of poliomyelitis are more seasonal than the primary serous meningitides and have an average higher cell count in the spinal fluid at the clinical start of the disease, with even decrease of the cell count from this time. In the primary serous meningitis the cell count does not reach its maximum until from the seventh to the ninth day. There is a greater tendency in the paralytic cases to increased albumin globulin and sugar values in the spinal fluid. The majority of primary serous meningitides in Denmark are at present regarded as most probably of poliomyelitic etiology.

Poliomyelitis in Denmark in 1937.—Lassen states that the highest incidence of poliomyelitis to date in Copenhagen was in 1937. The disease was not endemic in the schools. One hundred and twenty-six paralytic cases and sixty cases of primary serous meningitis, believed to be of poliomyelitic origin were treated at Blegdam Hospital. In at least 80 per cent of the patients with pareses the first signs of certain paresis occurred within the first six days of the disease. If after the first indications of paresis there is an interval of two or three days without progression, extension of the paresis is unlikely. About half of the paretic patients showed symptoms of disorder of the bulbopontile portion of the central nervous system. 44 per cent had paralysis of a nerve of the brain, in two thirds of these there was disorder of the facial nerve and in one sixth of the abducent nerve, and about one fourth of the patients had respiratory difficulty. Nineteen of these were treated in the respirator and two with artificial manual respiration. In two fifths of the cases there was complete restitution on discharge or complete restitution later was probable, in one fifth restitution was doubtful and in one fifth it was considered improbable. After-examination a year later in the main confirmed the prognosis. One fifth of the paretic patients died, the highest mortality being in the age group over 20. In eighteen cases death was due to respiratory paresis with complications, in seven to hyperpyrexia or bulbar paresis with respiratory difficulty. In twenty-one cases death occurred before the tenth day. In all the fatal cases bulbar symptoms were more or less prominent. Of the nineteen patients given respirator treatment six survived. The real field for the respirator, the author says, is for patients with spinal respiratory paralysis without bulbar symptoms. Most of the patients who died in the respirator showed increasing cyanosis without definite signs of circulatory insufficiency and in spite of apparently sufficient ventilation. It is suggested that in cases in which swallowing or coughing is impossible the respirator by its inspiration suction aspirates secretion from the upper respiratory passages into the smaller bronchi, thus compromising the arterial oxygen saturation.

Pfeiffer's Meningitis Treated with Sulfanilamide.—Eldahl reports that from 1920 to 1938 there were twenty-eight cases of meningitis due to Pfeiffer's bacillus, all in children, at Blegdam Hospital. In 1920 one patient recovered spontaneously; from 1921 to 1937 the mortality was 100 per cent. Of the four cases in 1938 three were treated with sulfanilamide, with recovery in two of these and transient effect in the third, fatal, case, in which the inflammation was particularly violent.

Eosinophil Leukemia.—Thomsen and Plum consider the case here reported of special interest because of the transition from typical eosinophil leukemia to a pure myeloblast leukemia, which, they say, supports the conception of this symptom complex as a special form of myeloid leukemia, and because of the microscopic establishment in the bone marrow of a cell type not described in the cases previously published. The nucleus is relatively small with sharply defined boundary, the structure close, often vacuolized and without nuclei, the protoplasm colorless or faintly blue, with a peripheral zone containing fine blue-green kernels. In some of the cells there were also eosinophil kernels like those seen in the eosinophil leukocytes in the peripheral blood. The cells in question constituted 40 per cent of the bone marrow cells on the first sternal puncture. The authors are inclined to consider them the parent cells of the abnormal eosinophil cells in the blood. Some eosinophil cells of normal structure were found in the blood and corresponding to them a number of normal eosinophil myelocytes in the bone marrow. The normal eosinophil cells are believed not to be included in the leukemic changes. Several cases of eosinophil leukemia are cited from the literature.

Bunnell Reaction in Infectious Mononucleosis.—Thomsen finds that the Bunnell reaction is a useful aid in the diagnosis of infectious mononucleosis, especially when combined with absorption according to Davidsohn, but that it fails in a not inconsiderable number of cases and a negative reaction therefore does not exclude infectious mononucleosis.

THE CAUSE OF CHILLS FOLLOWING INTRAVENOUS THERAPY

CHARLES M. NELSON, M.D.
RICHMOND, VA.

In the field of therapy there are at present no more valuable agents than those administered intravenously. Physiologic solution of sodium chloride, dextrose, arsphenamine and countless others are given daily in every hospital in the country. From the time these agents were first introduced, reactions consisting usually of fever and chills have followed their use. The cause of these reactions has been sought assiduously and every possible factor has been suspected. Extensive experiments have been carried out which resulted in the discovery of the cause and the elimination—in the laboratory—of these reactions. These results, unfortunately, have uniformly been published in journals dealing with the preclinical phases of medicine and have escaped the attention of the majority of those using intravenous medications in their daily practice. I believe that these results should be brought to the attention of the therapist, and accordingly I plan to summarize the results of others and to add further proof of a clinical nature to what is already proved in the laboratory.

The factors most generally considered to be the cause of reactions are (1) extremes in the temperature of the solution, (2) the amount of solution, (3) the rate of flow, (4) the concentration of the solution, (5) the glass and tubing used, (6) the p_H and (7) the water used in the preparation of the solution. Countless other possibilities have been mentioned, but those cited are held to be the usual offenders.

The first five of these factors were eliminated as a cause of chills in the following experiment: During the three and one-half month period from Sept. 15, 1935, to Jan. 1, 1936, a record was kept of every venoclysis given in the Hospital Division of the Medical College of Virginia, the record including the temperature of the solution taken by a thermometer at the wrist through which the solution flowed, the amount of solution, the rate of flow, the gage of the needle, the concentration of the solution, and the presence or absence of chill. The tubing used was pure gum rubber prepared by soaking in 4 per cent sodium hydroxide for six hours, then scrubbing and rinsing with green soap and water which was, in addition, passed through the tubing by syringes. The tubing was then boiled for ten minutes and tap water was run through it for twenty-four hours. Following this, distilled water was run through it three times and finally it was allowed to dry. The flasks used were hard glass thoroughly washed prior to autoclaving.

During this period a total of 680 venoclyses were given with eighty-two chills occurring either during or immediately after administration of the fluid, an incidence of approximately 12 per cent. The results are given in the accompanying table.

From these figures it will be seen that our percentage of chills was reduced from 28 to less than 3 during the period under consideration. Yet no one of the factors mentioned showed a consistent change. The method of preparation of the flasks and tubing had not been changed. Physiologic solution of sodium chloride or 5 per cent, 10 per cent or 15 per cent dextrose in either distilled water or physiologic solution of sodium chloride was still being used. The rates of flow still varied from 250 to 3,000 cc. an hour, the needles ranged from gage 18 to 22 and the temperature varied from 85 to 122 F. Tremendous amounts of fluids given rapidly would produce no chill, yet the following day, under the same conditions and with the same type of fluid, a small amount would cause an intense reaction.

Since there was no consistent change in any of these factors, although the percentage of chills decreased from 28 to less than 3 during this period, and since a careful check of the record of each chill revealed that no one factor or combination of factors was uniformly present when a chill occurred, it appears that they can be ruled out. This does not eliminate entirely the possibility that the glass and tubing used were the cause of occasional chills, since our records did not show which venoclysis set was employed when chills occurred, but it does rule out the possibility that they were the cause of the majority of the reactions.

With regard to the p_H, experiments have been performed on rabbits in which the p_H was varied from 4.6 to 8.0 without any reaction. This work was first done in 1923 by Seibert [1] and was repeated in 1934 by Banks.[2] It had been previously stated by Williams and Swett [3] that saline and dextrose solutions with a p_H of less than 6.5 produced chill and prostration. Our work neither refutes nor confirms this, since the p_H of our solutions was not determined. However, if we accept the rabbit as a suitable experimental animal, there can be no doubt from the work cited that the p_H is not a causative factor. That the rabbit is a suitable animal was shown both by Seibert and by Banks. The rabbit's normal range of temperature is known and also the usual fluctuations caused by environmental changes or by handling. Anaphylactic reactions are difficult to

This work would have been impossible without the active cooperation received from the administrative department of the hospital group of the Medical College of Virginia and from the Department of Physiology, and especially from Mr. George Snyder of the Department of Bacteriology.

produce. In addition, the reaction of chill-producing solutions is constant, consisting of a marked abrupt rise in temperature which usually persists from three to four hours. Unfortunately chills are not produced; but solutions that cause chills in human beings give this febrile reaction, and solutions giving this febrile reaction produce chills in human beings.

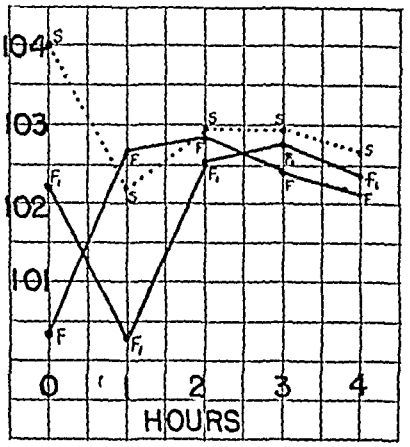

Chart 1.—This is self explanatory. It shows merely that the solutions used are nonreactive and that old saline solution is nonreactive if the proper precautions are taken. It also shows the normal temperature range of the rabbit. *F* and F_1 indicate fresh physiologic solution of sodium chloride. *S* indicates the solution 5 days old, autoclaved one hour after distillation.

In addition to eliminating the possibility of the p_H as a factor, Seibert at the same time showed that hemolysis, the absorption of atmospheric gases and the preponderance of various ions—potassium, sodium and the like—could be of no importance; the reader is referred to her articles for complete details.

This narrows the elimination down to the water used in preparing the solutions. During the period in which our percentage of chills was so abruptly reduced, only one factor of all those mentioned was changed. A new still was installed the latter part of October. As the table shows, two weeks later our percentage of chills was 3.3. It can be reasonably inferred that the majority of the chills were caused by distilled water either improperly distilled or contaminated after distillation.

Three and One-Half Month Record of Venoclyses Given in the Hospital Division of the Medical College of Virginia

Date	Venoclyses	Chills	Per Cent
Sept. 16-30	128	36	28.0
Oct. 1-15	121	19	15.0
Oct. 16-31	77	12	16.0
Nov. 1-15	86	8	9.0
Nov. 16-30	119	4	3.3
Dec. 1-15	71	1	1.4
Dec. 16-31	78	2	2.6

In an effort to determine the time of contamination, a series of 120 hypodermoclyses was run. Hypodermoclyses were chosen for several reasons; the type of reaction was familiar, the dextrose factor could be eliminated, reactions were more constant and less awe inspiring than with venoclyses, and the experiments could be readily controlled. Physiologic solution of sodium chloride was used in each instance and two different saline solutions were used, the first being the saline solution ordinarily sent down from the operating room and the second being a special saline solution made from water taken directly from the still, carried to the operating room, filtered, and immediately autoclaved. The method of preparing the ordinary saline solution was as follows: To water taken directly from the still sufficient chemically pure sodium chloride was added to make a physiologic solution. This solution was taken to the operating room and stored in a 5 gallon bottle from which, as needed, it was decanted, filtered into 1,500 cc. flasks and autoclaved. The bottle usually had to be replenished at the end of from forty-eight to seventy-two hours.

In this experiment 750 cc. of each solution, the special and the ordinary, was given on the lateral aspect of each thigh, the solutions being run in through different sets and with different tubing. The sets were taken at random from the hospital supply and consisted of one 1,000 cc. flask, a length of rubber tubing, an adapter and a needle. No effort was made to keep separate those used for the special saline solution. Twenty-four hours after the hypodermoclysis was administered the thighs were compared both subjectively and objectively. In 93 per cent of the cases the thigh receiving the ordinary saline solution showed a local reaction consisting of tenderness, redness, swelling and local heat, while the opposite thigh showed no reaction other than an occasional slight tenderness. The reactions suggested a severe, acute, superficial infection but in no case was there any formation of pus or any true cellulitis.

From this experiment it becomes apparent that saline solution freshly distilled and autoclaved is nonreactive, while a reactive factor develops in that allowed to stand without autoclaving. That it is not aging of the saline solution alone which produces the factor was proved by the special saline solution being allowed to stand for as long as five days after autoclaving and then being administered without causing a reaction. Supplementary proof is also obtained that the sets are not the cause of reaction, since we had no reactions with the special saline solution although the sets were chosen at random from the hospital supply.

Since immediate autoclaving prevents reactions, it follows that growth of some type must be occurring in and contaminating the ordinary saline solution. Accordingly, cultures were taken from the bottle from the operating room and the following organisms were found: Escherichia coli communior, Bacillus alcaligenes faecalis and Monilia albicans. We had previously considered algae as a possible contaminant, but these were ruled out by the discovery that water from the storage tank of the still was reactive while that taken directly from the still was not. No sunlight, necessary to the growth of algae, reached the storage tank.

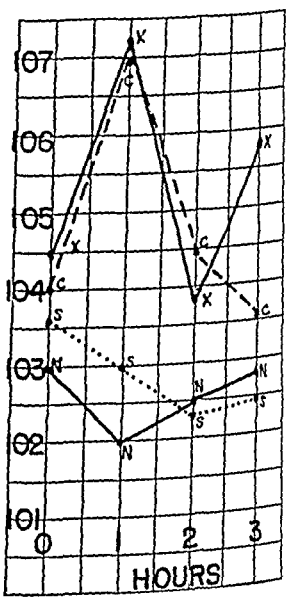

Chart 2.—The result of seeding distilled water with reactive organism and allowing growth to occur at room temperature for thirty six hours before autoclaving. One animal is included in which no injection was made, to show the curve produced by handling alone. *X* indicates B alcaligenes faecalis; *C*, Escherichia communior; *S*, physiologic solution of sodium chloride, and *N*, no injection.

It was thought probable that these organisms or their growth products were the cause of the chills and, in order to prove this, experiments were performed on rabbits. The following technic was used: Hundred cc. flasks were carefully washed with tap water, rinsed with freshly distilled water, partially filled with water taken directly from the still, taken to the operating room and autoclaved immediately. These flasks were then seeded with the organisms by removing a loopful of growth from the

agar slant and washing it in the flask. Broth cultures could not be used because of the possibility that the broth itself contained a reactive factor. The flasks were then recapped and allowed to stand at room temperature for periods varying from one to seven days, when they were again autoclaved. Not all the flasks were seeded, some being used for controls. Sufficient chemically pure sodium chloride was added to 10 cc. from each flask to make a physiologic solution and these solutions were injected into the ear veins of rabbits, separate syringes and needles being used for each solution. The temperature of the rabbits was taken at hourly intervals and graphs were made from these readings. A few of the graphs are shown here.

From these graphs and from others not included here it can be seen that on intravenous administration B. alcaligenes faecalis always produces fever and that Monilia albicans and uncontaminated saline solution never produce fever. It is also shown that the same contaminated water which produces fever in rabbits causes chills and fever in human beings.

Escherichia coli communior was included in only one study, because it was shown in 1911 by Hort and Penfold [4] that this organism —B. coli at that time— when injected into rabbits produces a febrile reaction. In their paper, one of the earliest on febrile reactions, they also include as reactors Bacillus typhosus, B. pyocyaneus, B. subtilis, Brucella melitensis, Bacillus pestis, Micrococcus catarrhalis, Staphylococcus albus and citreus, B. influenzae, the gonococcus, Corynebacterium acnes, the cholera vibrio and mallein. As nonreactors they list Staphylococcus aureus, pneumococci, streptococci, B. diphtheriae, B. anthracis, B. tetanus and tubercle bacilli. Seibert [5] in her later work added many other organisms to both groups. She divided them into four chief divisions: those which cause no reaction, those which cause only a slight elevation of temperature, those which cause a marked elevation of temperature —with this group she produced chills in human beings —and those which cause immediate prostration and death. The last group is quite possibly the cause of the terrific reactions which occasionally follow venoclyses and which are referred to in the literature as "speed shock." [6] To the already imposing list of reactors Banks added Pseudomonas scissa and Pseudomonas ureae, chromogenic bacteria common to most water supplies. Banks goes so far as to claim that the Pseudomonas organisms are the only producers of reactions as seen in venoclyses, basing his conclusions on the type of temperature curve seen in rabbits. He states that both pathogenic and other nonpathogenic organisms produce reactions, but they are delayed in appearance and with them the animal is much more prostrated than with the abrupt rise and fall of temperature seen in reactions produced by water seeded with Pseudomonas organisms. It seems to me that there is no necessity to limit these reactions to the activity of one group of organisms, since in our hands B. alcaligenes faecalis produces almost identical temperature graphs with those shown in Banks's paper and, in addition, I have shown that this organism will cause chills in human beings. Any organism which is capable of elaborating a pyrogenic substance which thrives at room temperature and which is a common contaminant may be the offender. No organism will ever be the offender if the distilled water is taken directly from the still— most storage tanks are contaminated by backflow of air when the still cools— and autoclaved immediately. Nor will chills occur except in isolated instances, and these not the result of venoclyses.

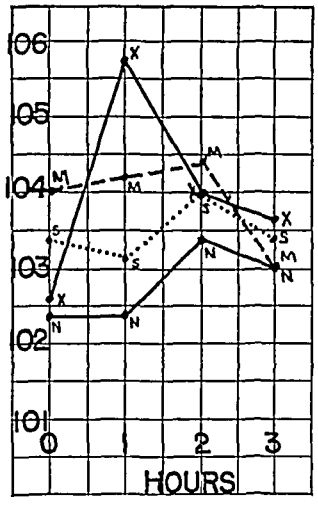

Chart 3.—Showing that a thirty-six hour culture of Monilia albicans is nonreactive. *X* indicates B. alcaligenes faecalis; *M*, Monilia albicans; *S*, physiologic solution of sodium chloride, and *N*, no injection.

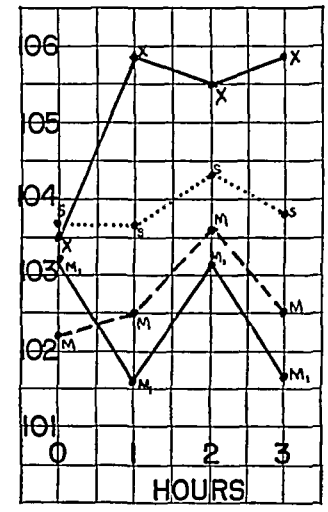

Chart 4.—Showing that a seven day culture of Monilia albicans in which the growth was so profuse that the water was turbid is also nonreactive. *X* indicates B. alcaligenes faecalis; *M* and M_1, Monilia albicans, and *S*, physiologic solution of sodium chloride.

It may be well at this point to summarize the known characteristics of the reaction-producing substance.

1. The substance is a product of bacterial growth.[7] It is not due entirely to the bacterial bodies themselves, since filtration through a Berkefeld filter does not render a reactive water nonreactive.[8]

2. It is heat labile. Boiling for six hours will produce a nonreactive water. Autoclaving, if sufficiently prolonged (from three to four hours) will also destroy the factor. The usual period of sterilization however tends to increase its activity.[8]

3. It is water soluble. A nonreactive solution placed in a dry sterile flask which has contained pyrogenic water and which has not been thoroughly washed will become reactive.[1] To digress for a moment, it is for this reason that the tubing and flasks may occasionally

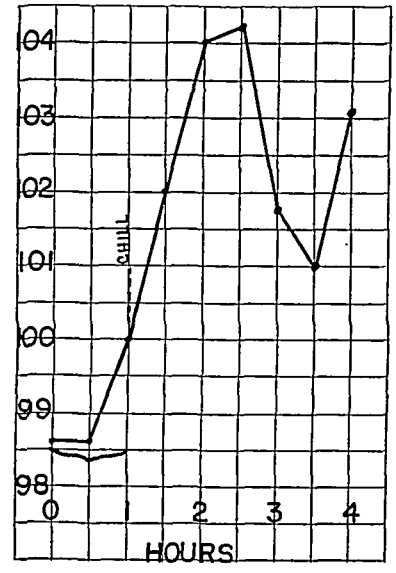

Chart 5.—The temperature of a patient with dementia paralytica who was given a solution of 5 per cent dextrose in distilled water. The dextrose was the 50 cc. ampule of 50 per cent dextrose offered for sale by almost all drug houses. The water was freshly distilled and autoclaved immediately, seeded with B. alcaligenes faecalis and allowed to stand at room temperature for twenty-four hours, when it was again autoclaved. Five hundred cc. was used.

be the cause of reactions, the pyrogenic substance being picked up as the solution passes through the set. If the tubing is prepared according to the method outlined earlier in this paper and any nonreactive water, distilled or otherwise, is passed through it three times prior to immediate autoclaving, this tubing will be nonreactive. Similar care must be exercised in the preparation of the flasks, funnels and storage bottles.

4. The substance is particulate in nature. It is held back by the pores of a 200 second Zsigmondy ultrafilter and passes through those of a 42 second filter.[9]

SUMMARY

Certain factors commonly thought to be influential in producing reactions to venoclysis are eliminated.

Another organism, B. alcaligenes faecalis, is added to the list of those known to cause reactions. At the same time Monilia albicans is eliminated.

Reactions to hypodermoclysis have value as a simple means of determining the presence or absence of pyrogen in the ordinary saline solution used in hospitals.

Further proof is added in support of the already proved statement that reactions to venoclysis are the result of bacterial contamination of the distilled water used in the preparation of the solutions.

THE FATE OF CHILDREN WITH PRIMARY TUBERCULOSIS

PHILIP T. Y. CH'IU, M.D.
PEIPING, CHINA
J. A. MYERS, M.D.
AND
C. A. STEWART, M.D.
MINNEAPOLIS

It was unfortunate that the discovery of the tubercle bacillus occurred during an era in which the causative organisms of so many other diseases and, even more important, so many preventive measures came to light. Thus tuberculosis, as soon as it was found to be due to a bacillus, was relegated to the general category of "infectious diseases." For many of the other infectious diseases, a vaccine or an antitoxin was found within a few years after the causative organism was discovered. Hence the unceasing effort toward finding an antidote or an immunizing substance overwhelmed the minds of the medical scientists from the tuberculin of Koch in 1890 to Calmette's BCG. Tubercle bacilli in various forms, types of products and amounts were tried with varying results.

Naegeli in 1900 found that the majority of people have traces of tuberculous infection in their bodies. Von Behring in 1903 showed that tuberculous infection in childhood is followed by a recrudescence of lesions in adult life. In 1907, with a tuberculin test that was an improvement on Koch's, Pirquet found that tuberculous infection is very prevalent. Subsequent work by other investigators showed that the higher the incidence of infection the higher also are the morbidity and mortality rates for the community, which fact in itself shows that an infection not only is not a protection from tuberculous disease but is a liability.

Much effort and work have been devoted to proving the immunizing property of the tubercle bacillus. It seems true that this bacillus does produce a certain amount of immunity. It also seems indubitable that primary infection, dormant for a time, can and does give rise to the so-called reinfection type of lesion in later life. Thus Rich and McCordock showed that tuberculous meningitis in the majority of cases originated from old foci of infection in or adjacent to the central nervous system. In the prevention of tuberculosis the question, then, is Which of the two factors is more preponderant, the immunity that a tuberculous infection produces or the subsequent hazard from such an infection?

One proposition is universally accepted: Without tubercle bacilli there can be no tuberculosis.

The history of the eradication of bovine tuberculosis is instructive. In one country all obviously diseased cattle were condemned; in another all infected cattle, those with a positive reaction to tuberculin were condemned. In the former country the number of tuberculous cattle was not appreciably reduced in ten years, while in the latter it was reduced to one tenth of the original figure.

This communication deals with a ten year follow-up of 446 children with positive reactions to tuberculin and 772 children with negative reactions. These children are from those observed in the first eight years (1921-1928) at the Lymanhurst Health Center, of

whom the total number was just under 6,000. No selection was made. If a patient was followed up for ten years or more he was included. Naturally those in whom tuberculosis developed at any time during the survey were included. Those who came with well developed tuberculosis, in some of whom the condition was proved by later examinations, were excluded; there were twenty-six of these. The majority of the children were either suspected of having tuberculosis or had been in contact with tuberculous patients, living or dead. In most cases the tuberculous patient was removed from the home as soon as was feasible after he was recognized as such. The sanatorium facilities are good in the community. This does not necessarily mean, however, that the contact was severed, as many of the sanatoriums allow their patients out for short intervals and all of them allow visitors over 14 years of age without giving them special care. Some patients refused to go to a sanatorium or remained there for only a short period. The exact amount of exposure is impossible to estimate, but the general impression is that there is no material difference between the two groups.

* Two patients with pleural effusion, one with Ghon's lesion and one with "marked calcification" had negative Pirquet reactions at first, but as their reactions soon became positive and they had such definite x-ray evidence it is considered justifiable to include them in the group with initial positive reactions.

All the tuberculin tests were done by the Pirquet technic except the follow-up tests done since 1930. When a test was recorded as "slightly positive" or the wheal described as one-sixteenth or one thirty-second inch in diameter it was judged by the results of subsequent tests. Early and subsequent roentgenograms were likewise correlated before a definite diagnosis was made.

The age distribution of the children is shown in table 1.

The positive reactors were regularly followed up; for most of them roentgenograms were taken at intervals of six months to a year and, when clinical tuberculosis was suspected, every one or two months. Of the 772 negative reactors 412 were located in a survey by the public health nurses, who saw the child if possible or else obtained information from such reliable persons as the parents, the family physician or the school teacher. The remaining 360 children were examined in the center by tuberculin testing or roentgenograms or both. The length of follow-up is shown in table 2.

The twenty-three positive reactors followed up less than ten years are those in whom the disease developed; of these twenty-one have died and two have been institutionalized or have disappeared. The four negative reactors are in sanatoriums.

COMMENT

It is evident from the figures in the tables that the infected children had roughly nine times the chance of getting clinical tuberculosis within ten years as did the originally noninfected children. With 15 per cent of the children who reacted positively to the tuberculin test and

had no other clinical evidence of disease falling ill within approximately the next ten years, it is obvious that a tuberculin reaction in a child is of far more significance than was formerly believed. If the morbidity and mortality rates continue for these children throughout life as they have begun, clinical tuberculosis will be as frequent among them as tertiary syphilis among persons with positive Wassermann reactions. This would seem to be sufficient evidence to dispel any great enthusiasm for immunity produced by the primary tuberculosis complex. Indeed, by the old criteria these are the persons who should have been immunized by reason of infections in childhood. One might maintain that the remaining 85 per cent have been immunized, but any argument in this direction at present would be nothing more than speculation; only time will tell, and since no such observations have previously been made it would be futile to venture an opinion. Suffice it to say that 15 per cent is a large toll to be exacted in so short a time.

TABLE 5.—*Summary of Survey*

	Total Number of Cases	Reinfection Type of Disease: Patient Died: Pulmonary	Extrapulmonary	Pulmonary	Extrapulmonary	Total	Percentage
Positive reactors	446	42	3	15	7	67	15.02
Negative reactors	772	11	1	1	0	13	1.68

Another useful fact obtained from these observations is that clinical pulmonary tuberculosis rarely appears until adult life. The average age at which these persons were first found to have the primary tuberculosis complex, as manifested by the reaction to tuberculin, was 7 years, but the average age at which they were found to have clinical tuberculosis was 18.9 years. Treatment of children with the primary complex has not been found to afford any more protection against

the clinical type of tuberculosis in adult life than similar treatment would be expected to provide against tertiary syphilis years later for persons with primary syphilis.

As there is no method of destroying tubercle bacilli once foci are set up in the human body, no method of artificial immunization has proved effective, and since years or decades after the initial attack lesions may become communicable, one is forced to use a method of control based on prevention of the initial infection. After all, this is fundamental.

SUMMARY

Four hundred and forty-six children with positive reactions to tuberculin but without clinical pulmonary lesions and 772 children with negative reactions were followed up for ten years. The average age at the first examination for the former was 7 years and for the latter 6.6 years. The average number of years of follow-up for the former was 11.3 and for the latter 10.95. At the end of the follow-up period it was found that sixty-seven of the positive reactors (15.02 per cent) were sick with the reinfection type of disease, while of the negative reactors only thirteen (1.68 per cent) were sick. Thus there were nine cases of tuberculosis in the positive reactors to one in the negative reactors. The ratio between the mortality for the positive reactors and that for negative reactors is 38 to 1.

VITAMIN A DEFICIENCY IN NORMAL AND TUBERCULOUS PERSONS

AS INDICATED BY THE BIOPHOTOMETER

Löhr's [1] investigations of the wound-healing properties of cod liver oil have stimulated many clinical studies. Of special interest is the work of Banyai,[2] who successfully treated lupus with topical applications of cod liver oil. In our laboratory the healing effect of cod liver oil applied topically to experimental tuberculous ulcers of the skin of guinea pigs has been demonstrated, and similar favorable results with certain fractions, obtained in the attempt to isolate the active substance, have been reported by Getz.[3] Since the fractions most active in the healing of tuberculous lesions are those containing the greatest amounts of vitamin A, the queries arise Are tuberculous individuals deficient in vitamin A? Will tuberculous human beings respond favorably to increased amounts of vitamin A? Are "normal" persons deficient in vitamin A? To answer these questions, the study here reported was conceived.

The work of Jeans, Blanchard and Zentmire [4] and later that of Jeghers [5] suggested the biophotometer [6] as a satisfactory instrument for the measurement of vitamin A deficiency, although Palmer and Blumberg [7] have disputed its value. Our study of several hundred normal persons was done preliminary to testing tuberculous subjects to note any changes when the vitamin A deficient persons were placed on an adequate vitamin A intake and to obtain a basis for comparison.

METHOD

The technic used was similar to that of Jeans.[4] In all cases the subject was placed in a dark room and allowed to remain ten minutes with the eyes closed before beginning the test. After a reading of the minimum light threshold had been taken, the bright light was turned on for three minutes. The next reading was taken as near as possible to twenty seconds after the bright light was shut off. It was almost never taken as much as thirty seconds after the bright light was extinguished; if so, the time of the reading was recorded. In taking the reading, the rheostat was turned so that the test light was dimmer than that which the subject could see. Then it was turned back slowly to the end point, the point where the center dot in the quincunx was just visible. This technic was rigidly followed throughout the work. Both the reading after the bright light and the curve of regeneration of the visual purple made with the two subsequent readings were used to adjudge the status of the subject. The pathologically deficient group (as defined by Jeans) included those who had a minimum light threshold after the bright light above 1 millifootcandle and subsequent readings that were correspondingly high The normal group included those who similarly had a minimum light threshold less than 0.6 millifootcandle and the lowest subsequent readings. The group classed as showing borderline deficiency gave readings between those obtained for the normal and the pathologically deficient group.

BIOPHOTOMETRIC RESULTS WITH NORMAL PERSONS

Of the 500 healthy persons tested, 300 were used as controls for comparison with tuberculous patients; 229 were medical students from all four classes and seventy-one were home economics juniors. The rest of the 500 were deemed unsuitable as a control group, since they had requested the test because of a suspected deficiency The data for the control groups are presented in table 1.

A history was taken of each medical student before the test was made, and the significant data are presented in tables 2 and 3.

RESULTS OF THERAPY

At first only persons with marked deficiency culled by the instrument were given treatment. Since 20,000 units of vitamin A per day in halibut liver oil [8] produced little or no change in six persons in two or three weeks, the dose was raised to 90,000 units a day. Some persons showed prompt response to this dose but others showed no change; 200,000 units of vitamin A daily in halibut liver oil did, however, initiate a response in fifty of the most deficient subjects in as short a period as two weeks. Usually the patients received this high dose until a favorable response was noted; then the dose was reduced to 100,000 units or less. All patients put on this treatment showed a reduction in their minimum light threshold, and only a few have failed to reach normal limits in two months.

TABLE 1.—*Results of Biophotometric Tests of Students*

	Pathologically Deficient, %	Borderline Deficient, %	Normal, %
229 Medical Students (November 1937)	6.55	12.22	81.22
71 Home Economics Juniors (February 1938)	11.27	15.49	73.24

In contrast, the response of five patients with borderline deficiency and two normal persons to 100,000 or more units of vitamin A was more prompt. In three weeks the minimum light threshold for all of these was reduced, and the persons with borderline deficiency had become normal. One of the persons showed, after the exposure to bright light, a reduction in his minimum light threshold from 0.36 to less than 0.05 millifootcandles. This would indicate that the state of vitamin A nutrition of the biophotometrically normal persons can be improved. That this may be of physiologic significance is suggested by the results of tests done with Dr. R. C. Herrin of the physiology department. Two persons with normal biophotometric readings and one with borderline deficiency were given 100,000 or more units of vitamin A daily in halibut liver oil, and urea clearance was determined before and after several weeks of treatment. Herrin and his associates [9] have reported that the urea clearance was almost doubled in these cases.

TABLE 2.—*Significant Data from Histories of Medical Students at the Time of the Biophotometric Test*

	Pathologically Deficient (15), %	Borderline Deficient (28), %	Normal (186), %
Frequent (more than 4 per year) or chronic colds	60.0	35.71	21.50
Postnasal drainage	53.3	39.29	25.27
Burning eyes	26.6	28.56	13.92
Acne	6.6	32.14	25.81
Dry skin	26.6	14.28	11.29
Early fatigue of eyes with night driving	33.3	35.71	16.66

The effect of single massive doses (2,000,000 units) on one normal person and on three with borderline deficiency are given in table 4. All subjects taking the massive doses of halibut liver oil experienced dull headaches but no other untoward symptoms.

All four subjects receiving the halibut liver oil showed a decrease in minimum light threshold, even subject 2 who had values consistently high in the normal range before the test. The peak was reached approximately four and one-half to five hours after consumption of the oil, and the next day the readings were back to the former level. Subject 5 was the same person as subject 4, tested five days later, when his readings had returned to the previous level. The change was so slight with carotene that it could well have been within the limits of normal daily variation, although this subject had never previously shown so large a change in one day.

RESULTS OF BIOPHOTOMETRIC TESTS OF TUBERCULOUS PERSONS

One hundred and ninety-seven mostly fever-free and ambulatory tuberculous patients, comprising all the persons with minimal disease available for testing and a representative group of those with moderately advanced and far advanced tuberculosis in three sanatoriums [10] in southern Wisconsin were tested during December 1937 and January 1938. Fifty-three per cent were found to be pathologically deficient (table 5). The stage of tuberculous involvement was not known to the biophotometric observer, but later the patients were grouped according to the standards of the National Tuberculosis Association by the chief resident physician in each sanatorium. The biophotometric results in each group are given in table 6.

TABLE 3.—*Dietary Habits of Medical Students at the Time of Testing*

	Pathologically Deficient (15), %	Borderline Deficient (28), %	Normal (186), %
Eat in restaurants	26.6	50.0	45.16
Cook and eat in living quarters	26.6	10.71	25.27
Eat in boarding house	46.6	39.29	29.57
Eat three complete meals per day	46.6	39.29	51.61
Eat two complete meals per day	26.6	39.29	36.02
Eat only one complete meal per day	26.6	21.42	12.37

RESULTS

It is impossible to tell whether the difference (table 1) between the medical students and the home economics juniors was due to seasonal variation, age, sex or group selection, but seasonal variation seems the most probable since the latter series was tested in February. The medical students were almost all males, and the home economics juniors were all females. The number deficient in each group is higher than one would expect; only 53 per cent of the deficiences could be explained on a dietary basis.

In comparing the data on the control groups with those for the tuberculous group one notes that 53 per cent of the latter group showed deficiency, as contrasted to 6.5 and 11 per cent of the normal controls. The tuberculous persons were somewhat older than the control subjects (table 5), although none were older than 50 and most of them were between 20 and 35. The number of persons with red hair was too small for the percentages to be of value, but the number of blonds may be sufficient. The fact that the percentage of blonds was twice as high in the deficient group as in the normal group seems important, since it is generally thought that they do not utilize carotene as effectively as do brunets. The favorable results obtained with

10. Muirdale Sanatorium, Wauwatosa, Wis.; Lakeview Sanatorium, Madison, Wis., and Wisconsin State Sanatorium, Statesan, Wis.

heliotherapy may be partly accounted for by selection of subjects to receive the treatment. The very sick persons are not given radiation. The data on subjects treated by pneumothorax are not particularly important but are included to give an indication of the clinical history. The figures on subjects given apicolysis and thoracoplasty imply that the sickest persons are the most deficient, since the milder lesions are not treated by apicolysis and thoracoplasty.

Again, in table 6 the results indicate that the persons with far advanced disease are most apt to be deficient. The increase in percentage of deficiency seems to be parallel with the increase of the tuberculous involvement, except that the frequency in the group with minimal tuberculosis was much higher than in the group with moderately advanced disease. This may be due to the fact that because of the small number, every person with minimal involvement was tested, and we may have tested many that were more intoxicated by their infection than were the persons with moderately advanced disease. The fact that the percentage of borderline deficiency with minimal tuberculosis is correspondingly low would seem to justify this assumption (table 6). Of particular import is the decrease in the frequency of normal vitamin nutrition as the tuberculous involvement increases.

Whether the tuberculous persons are deficient because of their infection or whether chronic infections develop because they have less vitamin A is still unanswered. One can only imagine what the percentage of deficiency would be in association with very active infection, for most of the subjects tested were ambulatory, fever free and not confined to "bed rest." The diets of the subjects seemed to contain amounts of vitamin A adequate for healthy persons. Forty per cent received additional vitamin A in fish liver oil although none received more than 30,000 units a day. This amount as a therapeutic dose is insufficient, as judged by our tests on nontuberculous persons. A preliminary study of the response of tuberculous persons to adequate vitamin therapy is under way.

TABLE 4.—*Effect of Massive Doses of Vitamin A*

Subjects 1, 2, 3 and 4 received 50 cc. of halibut liver oil (2,000,000 or more units of vitamin A), Subject 5 (subject 4 retested) took 2,000,000 units of vitamin A as carotene.*

COMMENT

The exact merit and significance of the various methods for determining vitamin A deficiency are still undetermined. Some workers have adapted the original Jeans technic to suit themselves, and others [11] have advocated changing the interpretation of the minimum light threshold so that fewer persons would be considered deficient in vitamin A. From our results it is suggested that many in the borderline group might be benefited by therapy. What may be a nonpathologic level of vitamin A nutrition for one person may give rise to symptoms in another, depending on factors not understood at present. We have presented data to show that the minimum light threshold may be lowered

TABLE 6.—*Patients Grouped According to Standards of National Tuberculosis Association as to Their Stage of Tuberculosis at the Time of the Test*

	Number of Cases	Pathologic Deficiency, %	Borderline Deficiency, %	Normal Level, %
Primary	8	37.50	12.50	50.00
Minimal	26	57.69	3.84	38.46
Moderately advanced	102	47.06	28.43	24.51
Far advanced	56	60.71	23.00	16.28

even in the so-called normal persons and that such a change affects the basic physiology of the kidney. Just what is the optimum amount of vitamin A for adults is unknown, but it would seem to be much more than has been previously recognized. The amount which was just sufficient to prevent xerophthalmia was once thought to be normal. Since the biophotometer has been developed it is recognized that a subclinical deficiency exists in many so-called normal persons. It is suggested that even normal persons according to the biophotometer might be benefited by more vitamin A. We must think of the optimum amount for the body and not the amount that will just prevent xerophthalmia or just prevent subclinical night blindness.

We have used the Jeans interpretation in spite of the fact that we have presented data to show that the normal level can be changed by intensive vitamin A treatment. The original interpretation must be adhered to in order that results obtained by different workers may be somewhat comparable. The whole curve of regeneration should be used to judge a person deficient and not merely the reading taken immediately after exposure to the bright light, since this reading is the hardest to take accurately.

The evaluation of the method should not be confused by the finding of vitamin A deficiency in what seems to be a perfectly normal person consuming a diet judged to be adequate. That individual differences in absorption, utilization and demand for the vitamin exist should

11. Corlette, Marvin B.; Youmans, John B.; Frank, Helen, and Corlette, Mildred G.: Photometric Studies of Visual Adaptation in Relation to Mild Vitamin A Deficiency in Adults, Am. J. M. Sc. 195: 54 (Jan.) 1938.

be apparent. Furthermore, it is probable that some persons on a large intake of vitamin A may not use it economically and may store comparatively little; when these persons are forced suddenly to live on a diet much lower in vitamin A but adequate for normal persons they show a shift toward the deficient range and then gradually return to a more normal reading. We have noted this in four subjects receiving from 150,000 to 200,000 units of vitamin A daily in halibut liver oil. This agrees with the observations of Davies and Moore,[12] who fed cod liver oil to rats until the livers showed stores of vitamin A which should have been adequate to last them more than a hundred years, but when the animals were put on a vitamin A-free diet the vitamin A content of the liver dropped precipitously.

There is no reason to doubt that the minimum light threshold is intimately related to the state of vitamin A nutrition and can be lowered with vitamin A therapy. That the biophotometer does measure or indicate changes in the state of vitamin A nutrition is also apparent from our data. Some authors have failed to draw similar conclusions because of insufficient dosage and inadequate periods of treatment; others have become confused by the influence of learning factors and daily variations in the subject's response to the test. The poor or slow absorption of carotene may have contributed to the confusion. Our figures with carotene, while for only one subject, agree with those of Clausen[13] and of Drummond, Bell and Palmer,[14] who concluded that preformed vitamin A is absorbed more rapidly. Even with 200,000 units of vitamin A in halibut liver oil it takes almost two weeks to get a significant therapeutic response in some persons. We have noticed this especially in subjects who had a minimum light threshold above 3.98 millifootcandles, the limit of our instrument. This immediately suggests the existence of other factors affecting the utilization.

CONCLUSIONS

1. The biophotometer gives an indication of the state of vitamin A nutrition of adults.

2. Normal healthy persons (college students) are not infrequently deficient in vitamin A. Pathologic deficiency on the basis of Jeans's interpretation of the biophotometric readings existed in 6.5 and 11 per cent of two control groups.

3. All persons with a high minimum light threshold adjudged deficient in vitamin A benefited from treatment with halibut liver oil in that their light threshold was lowered.

4. Previously advocated therapeutic doses of vitamin A in halibut liver oil were found grossly inadequate as judged by the response shown by the biophotometer. Larger doses (up to 200,000 units daily) gave a response reasonably prompt in pathologically deficient and very prompt in borderline subjects.

5. In 53 per cent of the tuberculous persons tested there was a deficiency in vitamin A.

6. The vitamin A deficiency paralleled the severity of the tuberculosis.

CONTRACEPTIVE METHODS

IRVING F. STEIN, M.D.
CHICAGO

Medical literature records that contraceptive methods have been used since about 2000 B. C.,[1] and evidence is at hand to the effect that even preliterate societies were familiar with such practices. The latter were confined chiefly to abortion and infanticide as a means of birth control, but magic rites were also performed by the medicine men. Primitive peoples also made tampons of roots, seaweed, rags or chopped grass and pills of tannic acid or opium, which they inserted as contraceptives; seed pods were used by them to serve as female condoms.

Among the earliest Egyptian records, notably in the Petri papyrus (1850 B. C.), prescriptions compounded as contraceptive aids contained "crocodile dung and ant paste, and honey." In the Ebers papyrus, prolonged lactation was encouraged for proper spacing, and the first reference to the use of a lint tampon for prevention of conception is to be found. A prescription for acacia tips, honey and lint to be inserted into the vulva is also recorded there.

Coitus interruptus and the use of sponge are referred to in Talmudic writings and in Aristotle's "Historia Animalium" (2 B. C.), the use of oil of cedar, ointment of lead or frankincense commingled with olive oil smeared on the cervix is described. Medicated pessaries of peppermint and honey inserted before coitus and pepper introduced afterward were methods advised by Dioscorides. Soft wool inserted into the cervical canal was one of many methods described by Soranos. Vinegar, one of the most widely used of the present day household remedies, was first mentioned in the literature of the sixth century in connection with astringent preparations such as alum, pomegranate and nutgall for prevention of conception.

Among the Chinese "Complete Collection of Valuable Prescriptions for Women," first published in 1237, quicksilver, gadfly and medicinal leeches taken internally were recommended both for contraception and for the production of abortion. A pill made of quicksilver fried a whole day in oil and taken on an empty stomach was said to result in permanent sterility without incurring bodily injury. A preparation of white lead was given prostitutes each month to suppress the menses and prevent impregnation.

In India a number of methods were used, varying from the practice of coitus obstructus to the drinking of sour rice water on certain days of the month and the precoital insertion of rock salt dipped in oil. There also one finds reference to the postmenstrual fumigation of the vagina with neemwood smoke to prevent pregnancy, and smearing it during menstruation with Palasha seeds mixed with honey and ghu.

Condoms probably had their origin in Japan, and examples of both hard and soft sheaths (tortoise, horn and thin leather) have been preserved to our day. Rubber condoms were introduced in Japan in 1871 after the process of the vulcanization of rubber became known. Women, chiefly prostitutes, inserted bamboo tissue paper tampons or disks of oiled paper into the vagina for contraception.

Islamic methods included along with many medicinal prescriptions for both male and female the practice of

1. Himes, N. E.: Medical History of Contraception, Baltimore, Williams & Wilkins Company, 1936; J. Contraception **2**: 99 (May) 1937.

coitus interruptus (withdrawal) and also the use of the "safe period." The latter, however, was a reversal in time of the present day theory. The use of suppositories of doe rennet or of elephant dung and honey were also among their methods.

In all sections of the world during the Middle Ages, various magic methods were in practice, but Himes

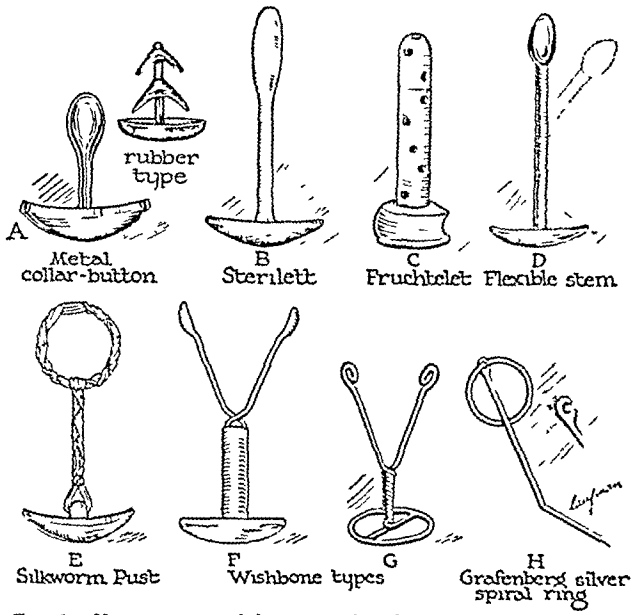

Fig. 1.—Various types of intracervical and intra-uterine contraceptive devices (adapted from Dickinson and Bryant and modified)

says that their effectiveness was probably very limited. It was a common belief that the seeds of fruitless trees, used medicinally, produced fruitlessness, the analogy being quite obvious.

In England, a year before the epochal essay of Malthus was published (1797), Bentham advised the use of the sponge tampon for contraception in order to reduce the British poor rates.

Many physicians feel that the present interest in contraception is either a temporary wave of reform or a social and economic problem peculiar to the tempo of modern times. But it is obvious from the foregoing that contraception was known and practiced by every race and civilization, from primitive savages who depended on tabus, magic and infanticide, down through the ages to the twentieth century. It now becomes our task to evaluate the methods which have persisted and those which have been evolved in our day. There is a definite need to inform the medical profession of the facts.

In this communication, purely physical methods will be considered. Various types of mechanical contraceptives have been developed. For intra-uterine use there are such devices as stems and rings, and as intracervical contraceptives there are buttons, stems and tubes, and combinations of rings and stems have been employed for many years. In addition, there are cervical caps and cups, vaginal occlusives, such as diaphragms, tampons and sponges, condoms or sheaths of both male and female types, and glans condoms. Some methods of contraception combine the use of some of the physical contrivances mentioned with chemical agents such as jellies, suppositories, tablets, powders and douches. The latter may also be used alone. For the purposes of this contribution, discussion will be limited to those methods which are to be condemned as contraceptives because of their possible harmful effects.

INTRACERVICAL AND INTRA-UTERINE DEVICES

Stem Pessaries.—Intracervical and intra-uterine stem pessaries used for contraceptive purposes claim the advantage of requiring but a single introduction by the physician and may be left for months or years. They are intended for long protection and do not require the cooperation of the patient. They need be removed only in case of bleeding or purulent discharge, pain or fever, and in the event of pregnancy.

The stem pessary had its origin in a device known as a "uterine elevator" (1863) for the correction of retroversion. This pessary was soon replaced, however, by a stem or tube calculated to facilitate conception by straightening the uterine canal and thus aiding the passage of spermatozoa to the fallopian tubes. Subsequently a split spring stem was developed for intra-uterine use in order to discourage implantation of the ovum. These contraptions, according to Dickinson,[2] while successful in skilled hands, resulted in many infections and in occasional deaths. The vaginal corrective pessary gradually replaced the "elevator" in the treatment of retroversion, and long uterine stems were shortened and modified in an attempt to obviate the inflammatory complications which attended their use.

Stem pessaries are made of heavy metal, such as gold and silver, and also of aluminum alloy, hard rubber, bone and even glass (Baldwin) and are chiefly employed by physicians for the treatment of sterility, dysmenorrhea, acute anteflexion of the uterus and hypoplasia.

At first, stems were held in place by means of a vaginal pessary and later were attached to caps or buttons which fitted over the external os. Some stems were split into Y or V shapes so as to be more effectively retained. The types of stems in use are often designated as collar-button, mushroom, butterfly, wish-

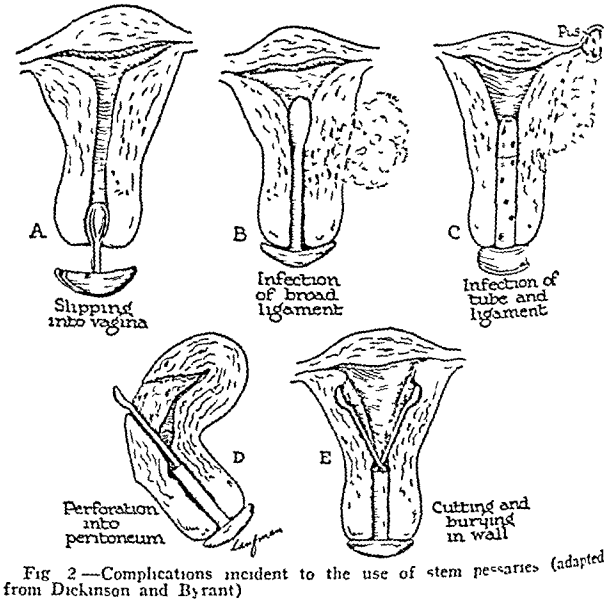

Fig. 2.—Complications incident to the use of stem pessaries (adapted from Dickinson and Byrant)

bone or Y-shaped stems, and specific instruments were known as the Sterillett, Fruchtelet and the Pust pessary; the latter consists of a ring of silk worm gut twisted into a stem which is attached to a glass button. The various types mentioned are illustrated in figures 1 and 2.

Although the use of the stem pessary has been largely discontinued by the medical profession because of

2. Dickinson, R. L., and Bryant, L. K.: Control of Conception, Baltimore, Williams & Wilkins Company, 1931.

uterine injury and pelvic infection (7 per cent according to Rawls [3]), there still appear to be some champions of these devices. Weir,[4] for example, reported recently a satisfactory experience of more than fifteen years' employment of the stem for the cure of dysmenorrhea. He did not use it as a contraceptive, however, as he believes that there are more satisfactory and less risky methods available. Weir inserted the stem pessary in 318 patients, in 91 per cent of whom the instrument was left for at least six months. While no complication appeared in the majority of cases, twenty-five patients had to have the pessary removed because of bleeding, cramps or both, one because of vaginal irritation and two for apparent pelvic infection. One of his patients became pregnant while wearing the stem and continued satisfactorily for two months after its removal, when abortion occurred after a fall. Kennedy, in discussing Weir's paper, stated that he has discontinued the use of the intra-uterine stems since he was obliged to operate on two patients for tubal infection following the insertion of the stem pessary for dysmenorrhea. Gellhorn [5] stated that he had used intra-uterine stems in hundreds of cases for relief of obstructive dysmenorrhea and sterility, and also for infantilism, with good results. However, these reports are counterbalanced by an increasing number of histories of serious pelvic infection and quite a few deaths resulting from this practice. Robert Frank [6] is of the opinion that carcinoma as well as uterine and cervical infection may be traced to the use of these devices and reports that Neugebauer collected reports of six cases in which neglected pessaries caused irritation on which cancer developed. Of course there is no proof that the pessary was the direct cause of the malignant condition.

In my own experience, operation was required in a patient for a unilateral tubo-ovarian abscess which resulted from the use of a Y-shaped silver stem inserted by a physician one year previously as a contraceptive. When bleeding and fever developed, the physician removed the stem. The pelvic inflammatory disease continued and an abscess formed, necessitating surgical intervention.

According to Curtis [7] the metal cervix pessary causes endometritis and obstruction to drainage, resulting in widespread pelvic infection. He also states that pelvic cellulitis may develop from a lost stem, which frequently works its way upward into the uterus and produces a foreign body infection. Furthermore, stems may perforate the uterine wall or become embedded and so create a pathway for the ascent of bacteria into the uterus. Sussex [8] reported a case in which hysterectomy was required because of perforation by a gold stem pessary. Cooper,[9] after discussing the use of various intra-uterine stems and stating their disadvantages, warns that numerous infections and some deaths have been reported. Warner [10] also stresses their dangers.

Pregnancy may occur in the presence of an intracervical pessary and, according to Norman Haire,[11] if such a device remains longer than one month it is likely to cause abortion; such abortions are often accompanied by sepsis. He describes a variety of pessaries which are utilized for contraception and particularly condemns the use of the Fruchtelet. All these devices, he says, exert a centrifugal pressure on the uterine walls, which after some time produces necrosis and ulceration. He regards the stem as a dangerous instrument, for he has never seen a case in which its presence was not accompanied by a pathologic condition. Abscess of the uterus and tubes and fatal peritonitis have been observed. In a case in which the "gold pin" had ulcerated through the wall of the uterus, hysterectomy was required.

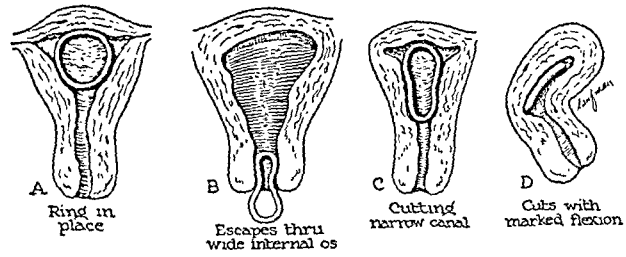

Fig. 3.—Gräfenberg intra-uterine contraceptive ring (adapted from Dickinson and Byrant).

Siddall [12] comments that it is not uncommon for a physician to be called to treat an illness resulting from the use of the intra-uterine pessary. He described a case in which he had difficulty in removing one of these pessaries because the cervical tissue had grown into the openings of the button. The patient was two weeks overdue when severe bleeding associated with high fever occurred. He mentions the cases reported by Rübsmen and Richter and by Royston, who removed pessaries during early pregnancy for like reasons, and states that in Kehrer's opinion if a stem pessary is inserted (accidentally?) during early pregnancy and is left for one week it may cause endometritis, resulting in salpingitis, parametritis, pelvic peritonitis and even death.

According to Dickinson and Bryant,[2] the two types of stem pessary which are chiefly responsible for the inflammatory complications and deaths are the "Sterillett" and the "Fruchtelet." These authorities have collected statistics on the morbidity and mortality incident to the use of such devices and report that, among others, Gummert collected records of ninety-two pregnancies which supervened in spite of the presence of the stem. Abortion occurred in seventy-eight cases, 80 per cent of which were septic; there were thirty-seven cases of peritonitis and seven perforations. They also quote D. P. Smith, who recorded two deaths from general sepsis resulting within two weeks of the insertion of wishbone pessaries by a general practitioner. Reist collected reports of 381 cases in which there were seventeen deaths from general peritonitis or sepsis, eight of which, however, were from stems deliberately inserted to produce abortion. Among the complications noted were nine perforations, forty-four cases of peritonitis and sixty-two septic abortions.

Intra-Uterine Rings.—A type of intra-uterine device, known as the Gräfenberg ring (fig. 3), has been extensively employed abroad for a number of years as a contraceptive. Three types of rings were utilized—a star of silkworm gut, a circle of silkworm gut and, finally, a spiral silver ring. The ring is inserted into

the uterine cavity after dilation of the cervix to number 5 or 6 Hegar, and the presence and location of the ring must be checked up from time to time by means of the uterine sound or by x-ray examination. The occurrence of bleeding or pain necessitates removal of the ring, a procedure more difficult than its introduction. On the other hand, the ring may slip out accidentally and unobserved by the patient, thus entirely defeating its purpose. It may become displaced. In its presence normal pregnancy rarely occurs, but ectopic pregnancy is in no way prevented by the ring.

According to Robert Meyer, who examined the endometrium of fifteen patients who wore the ring one year or longer, no inflammatory change is produced by its presence. Stefko and Lurié [13] have shown that when pregnancy does occur with the ring in the uterus the embryo may be injured, resulting in deformed children. Leunbach [14] of Copenhagen at first reported favorably on the use of the silver Gräfenberg ring but in 1930 withdrew his endorsement. In 12 per cent of his patients, bleeding and pain required its removal.

Gräfenberg,[15] the originator of the ring, who has used it for many years, had ninety-nine bad results in 1,081 cases, but less in the case of the silver ring than when silkworm gut was used. Thirty-one pregnancies occurred in his series, four of which took place while the ring was in the uterus and twenty-seven after the ring had been lost. Thus failures occur in about 3 per cent of patients. Inflammation occurred in seventeen patients; furthermore, replacements had to be made in 408 cases from one to eight times, a total of 1,390 instances. No mention is made in the literature of malignant conditions resulting from the use of these intra-uterine devices. In cases in which inflammation occurs, one would expect sterility as a sequel.

Green-Armytage [14] reported a case in which pregnancy took place in the presence of the ring, which had been inserted six months previously; the ring became embedded in the chorion, causing pain, discharge and fever. Cregan [15] observed a patient who became pregnant while wearing a Gräfenberg ring; septicemia developed following otitis media, and abortion ensued. Andrews,[16] in an article entitled "Migrating Gräfenberg Ring," was required to perform vaginal hysterotomy when the patient was four months pregnant for removal of the ring, which had become embedded in the wall of the cervix beneath the bladder reflection. Murphy [17] found a Gräfenberg ring in the broad ligament during laparotomy; a normal pregnancy was present at the time. Carleton and Phelps [18] experimented with Gräfenberg rings on rabbits and concluded that the devices should be made of gold rather than of silver, since the latter become brittle and are liable to break owing to the slow formation of silver sulfide. They observed no hypertrophy or inflammatory changes in the endometrium due to the presence of the ring but they did note flattening and irregularity in the shape of the cells in the grooves in which the ring lay, accompanied by pressure atrophy of the adjacent glands.

The Gräfenberg ring has not enjoyed extensive popularity in this country, and Dickinson has shown that in order to use such a device intelligently one must first have an accurate picture of the uterine cavity such as may be obtained by x-ray examination after instillation of iodized oil or other contrast mediums, for there are many variations in size and shape of the uterine cavity in the normal individual.

There are very few justifiable uses for the stem pessary at the present time, one of these being its insertion following cervical amputation, to prevent stricture. In this instance, however, the necessity for its use is limited to but a few weeks. In spite of the satisfactory experiences of Weir, Gellhorn and others, its use for other conditions, such as dysmenorrhea, has been largely discontinued by gynecologists. The use of intra-uterine and intracervical stem pessaries for contraceptive purposes is to be condemned, since it has been shown by the numerous reports quoted that not only do failures occur but serious damage frequently results to the pelvic organs. Cases of endometritis, parametritis, salpingitis, perforation and peritonitis are cited, and even deaths have occurred.

In the case of the intra-uterine ring complications are less likely to occur, but repeated observations are required to ascertain the proper location of the ring, either by means of x-ray examination or by intra-uterine instrumentation. Pregnancy has occurred in its presence and complications have been reported from this source. Bleeding and cramps may require removal, which at times is somewhat difficult owing to the flexibility of the device.

INTRAVESICAL ROENTGEN THERAPY OF CANCER OF THE URINARY BLADDER

SIDNEY C. LEVINE, M.D.
PATERSON, N. J.
GEORGE T. PACK, M.D.
NEW YORK
AND
JAMES S. GALLO, M.D.
HALEDON, N. J.

During the past decade, x-ray therapeutists in this country have been especially interested in the development of supervoltage roentgen therapy. In Germany, however, where the cost of radium is prohibitive, physicists and radiologists have devoted some attention to the construction of low voltage x-ray machines for therapy in attempts to approximate the same conditions obtained in radium treatment. The superior value of radium as it is generally used in the treatment of cancer cannot be attributed to a more selective action of the gamma rays than of x-rays on cancer cells but rather to the fact that the radium-skin distance is short and that most of the energy is absorbed in the tumor and tumor bed. Radium has given excellent results in the treatment of superficial cancers because of this characteristic distribution of the dose in tissues. The effect obtained from interstitially placed radium element needles or radon seeds in proper dosage has approached the ideal requirement, namely the destruction of all cancer cells with the least destruction of the normal surrounding tissues. With interstitial radium or radon seeds the source of the radiation is in the tumor itself, and because of the inverse square law there is a rapid

From the Josephine Lendrim Tumor Clinic, Paterson General Hospital, Paterson, N. J.

decline in the effect of the dose, and the surrounding tissues are damaged only slightly. The use of radium, however, involves expense and complicated technic in application and presents some difficulties in the protection of surrounding normal tissues. These disadvantages have stimulated the attempts to find an x-ray

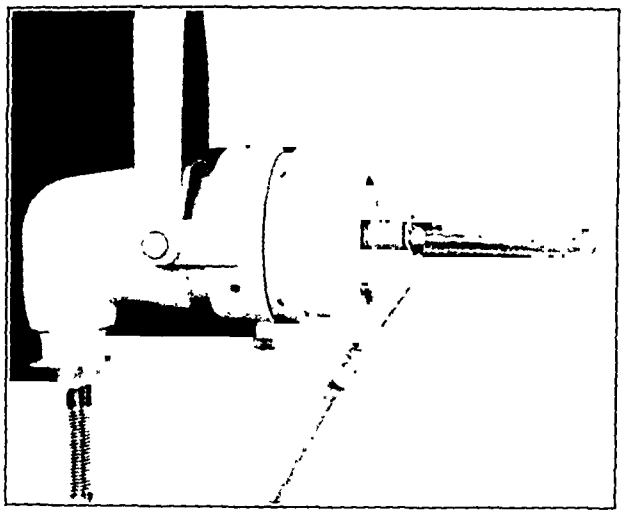

Fig. 1.—Chaoul x-ray tube for low voltage contact or short distance roentgen therapy.

tube which would combine the advantages of radium dose distribution and the economy, efficacy and convenience of the x-rays.

DESCRIPTION OF CHAOUL ROENTGEN APPARATUS

Special x-ray tubes furnishing a dose distribution similar to radium were designed many years ago and then abandoned because of technical difficulties concerned with the prevention of shock to the patient. These difficulties were subsequently overcome and the short distance or contact x-ray method was developed.

Schaefer and Witte of Göttingen, Germany, experimented in 1929, using a Lenard tube and cathode rays only; they later added a metal filter over the tube opening which did not permit the emergence of the cathode beam and served as the anode. They were interested in the radiation therapy of gynecologic neoplasms, which are usually situated deeply, so they designed an apparatus operating with 90 to 100 kilovolts and 4 milliamperes. The thin copper filter or transmission anode was plane, planoconcave or planoconvex to modify the shape and focal sharpness of the emergent beam.

Chaoul of the Charité surgical clinic, Berlin, designed an apparatus for low voltage, short distance or contact roentgen therapy. This apparatus is essentially limited to a voltage range of 50 to 60 kilovolts with a filtration of 0.2 mm. of copper. The anode is so placed that the tube operates at contact or at from 3 to 5 cm. target-skin distance. It has applicators or cones of various sizes and shapes to place against the cancers to be treated. These attachable cones are small and can therefore be placed in the various cavities of the body. The Chaoul x-ray machine is necessarily shock proof.

PRINCIPLES OF CONTACT OR SHORT DISTANCE ROENTGEN THERAPY

The short distance or contact x-ray treatments make possible the delivery of doses to the tumor sufficient to disintegrate tumor cells and yet spare the healthy surrounding tumor bed by using small fields sharply localized about the tumor. It furnishes limitation of depth effect by producing a steep energy gradient. The latter is obtained by decreasing the target-skin distance and the voltage delivered to the tube. With this apparatus a soft x-ray beam is utilized, and these rays are absorbed in the superficial tissues. For contact application the dosage rate is approximately 800 roentgens per minute; for a target-skin distance of 3 cm. it is approximately 88 roentgens per minute, and for a target-skin distance of 5 cm. it is approximately 36 roentgens per minute. The intracavitary beam of low voltage x-radiation is restricted to the desired areas with an accuracy that is not possible even with radium. It obviates the necessity of all the unsatisfactory protective devices necessary when radium is used. This apparatus, of course, does not take the place of radium for all types of applications. It has only a specialized usefulness. Chaoul recommends contact therapy for any superficial tumor. The use of this method has been extended to include all tumors that could be made accessible by a surgical procedure.

PRINCIPLES OF INTRAVESICAL ROENTGEN THERAPY (AUTHORS' METHOD)

Heretofore the routine method in the treatment of carcinoma of the bladder has been cystotomy, endotherm excision with a snare of the tumor if it is papillary and interstitial implantation of radon seeds into the base of the cancer. This was followed usually by external high voltage roentgen therapy.

The authors conceived the idea that this scheme of treating bladder carcinomas might be improved on by making the cancer of the bladder accessible not for a short time but over an extended period and by treating the cancer thus exposed by repeated fractionated doses

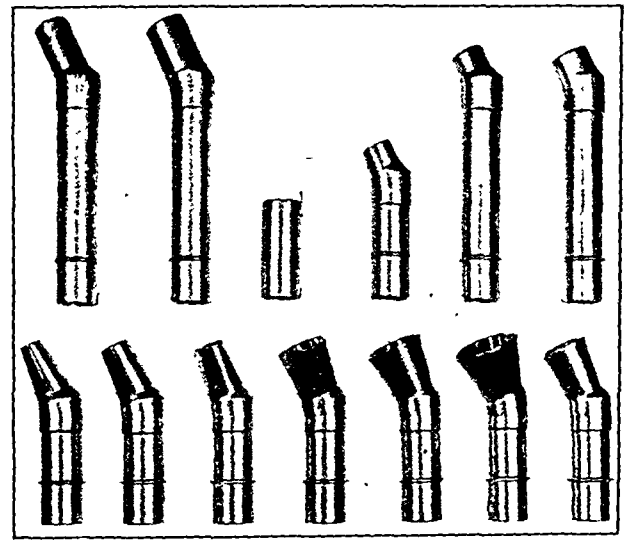

Fig. 2.—Cone attachments showing ports of various sizes and shapes. These cones may be sterilized and placed in position before the x-ray tube is inserted.

of low voltage x-rays applied at short distances. By use of the Chaoul low voltage x-ray outfit, a maximum amount of radiant energy is delivered directly to the cancer with the least amount of injury to the adjacent healthy bladder. This method further obviates the intense reaction and damage to the skin which results from the use of external high voltage x-rays. The method of treatment devised by us consists of (*a*) marsupialization of the bladder, (*b*) endotherm excision

of the bulk of the cancer when possible and (*c*) maintenance of an opening into the bladder so that the low voltage Chaoul tube may be repeatedly inserted against the cancer at the base of the bladder. Our brief experience with this method has convinced us that it has many advantages and no apparent contraindications or disadvantages.

ADVANTAGES OF INTRAVESICAL ROENTGEN THERAPY IN CANCER OF THE BLADDER

The advantages of intravesical roentgen therapy in cancer of the bladder are the following:

1. Ease and accuracy of application.
2. That the dosage delivered is almost the amount of dosage received by the tumor itself, in contradistinction to other methods of irradiation.
3. Sharp limitation of radiation effect to the cancer.
4. Minimum damage to surrounding healthy tissues.
5. That accessibility of the cancer can be maintained for an indefinite time, thereby allowing constant observation of the cancer and the degree of regression, permitting changes in the upper limits of dosage.
6. Freedom from radiation sickness.
7. Quicker and more comfortable convalescence.
8. Reduction of incidence of bladder infection and, because of the exposure, more satisfactory treatment of the infected bladder.

TECHNIC OF MARSUPIALIZATION OF THE URINARY BLADDER

The technic of marsupializing the bladder is as follows: A midline incision, starting about one-half inch above the symphysis pubis and extending for about

Fig. 3.—X-ray tube in position in urinary bladder through a marsupialized cystostomy.

4 inches toward the umbilicus, is made through the skin and fascia. The rectus muscles and fascia are separated in the midline and the bladder, which has previously been distended with water, is approached. The peritoneum is reflected by means of the index finger of the right hand, covered with wet gauze, from its lowermost attachment up to the highest point possible in the front of the bladder. The peritoneum and prevesical space as well as the sides are covered with moist laparotomy pads and retractors placed over them, giving a good exposure of the bladder. The bladder wall is grasped by two Allis clamps at a point just below the reflected peritoneum. A trocar is then intro-

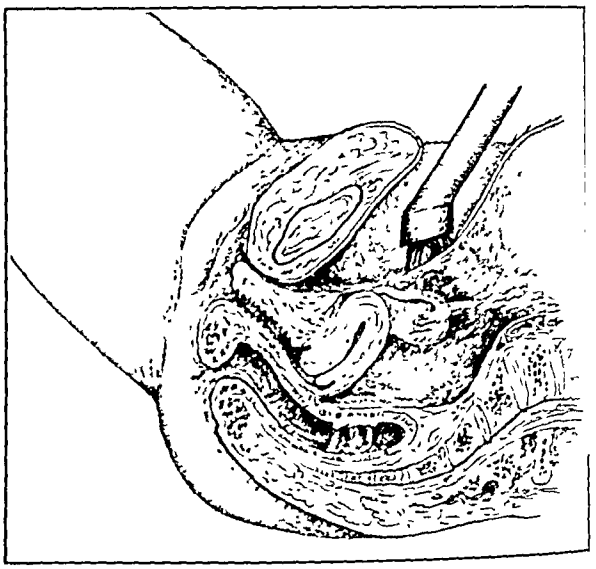

Fig. 4.—Diagrammatic sagittal view of x-ray cone in position

duced into the distended bladder and most of the contained fluid drained. The edges of the opening made by the trocar are now grasped by Allis clamps, which hold the mucosa as well as the muscle. An aspirating tube is then introduced through the cystotomy opening to withdraw the remaining fluid in the bladder. The opening in the bladder is now enlarged downward and wire retractors are inserted so that the interior of the bladder can be well visualized. At this time, if it is possible and the tumor is bulky, it is excised at its base by the cutting current of an endotherm snare. The bleeding is stopped by bipolar endotherm coagulation. The edges of the opening in the bladder are now sewn to the skin and rectus fascia by chromic catgut sutures. A large Marion drain 28 mm. in diameter, about which is wrapped sterile gauze moistened with sterile olive oil, is left in the marsupialized bladder. A thick dressing is then applied to the wound to absorb any excessive moisture. Petrolatum gauze is placed around the wound to protect the skin. The Marion drain is then connected with a rubber tube leading to a sterile bottle attached to the bed.

Four or five days is now allowed to elapse to insure a definite anchoring of the bladder wall to the abdominal wall. The patient is now ready for the intravesical insertion of the Chaoul x-ray tube.

TECHNIC AND DOSAGE OF INTRAVESICAL ROENTGEN THERAPY

The patient is given one-fourth grain (0.015 Gm.) of morphine sulfate one hour before the treatment is begun. For the first few treatments until the wound is well healed this narcosis may be supplemented by small doses of sodium evipal or avertin with amylene hydrate administered rectally. The wound on the abdominal wall is draped, and sterile precautions are taken. The Marion drain is now removed. Sterile gloved fingers are then inserted into the bladder and the cancer is

carefully palpated. A cone is chosen which will adequately cover the entire cancer. The cones to be attached to the Chaoul tube permit a target-skin distance of from 3 to 5 cm.; the selection of one or the other depends on the thickness of the cancer. It should be remembered here that not only the attached cones are within the bladder cavity but also the x-ray tube itself; the roentgen rays in fact are generated in the tube within the bladder at a distance of only 3 to 5 cm. from the cancer. The cone is placed in the desired position and the tube stand is manipulated so that the anode end of the tube can be slipped into the open end of the cone. The treatment is now ready to begin. The optimal fractional doses have not yet been found, but 2,500 roentgens have been given every other day. The bladder is kept open and the cancer is palpated at the time of each treatment in order to determine the degree of regression. It has been found that nine or ten treatments over a period of eighteen or twenty days for a total dosage of 22,500 or 25,000 roentgens has caused satisfactory regression. The total dose will naturally depend on the degree of regression observed.

At the conclusion of the roentgen treatments the marsupialization is maintained for frequent palpation of the bladder wall. When it is definitely decided that sufficient radiation has been delivered to the tumor area and the patient's condition warrants it, a secondary operation is performed for the replacing of the bladder in its normal position and closure of the wound of the abdominal wall.

The technic for this secondary operation is as follows: The marsupialized bladder is separated from the skin and rectus fascia and dropped down into the pelvis. The bladder wound is sewn about a mushroom catheter. The abdominal wall is now repaired as for a hernia. The suprapubic tube is left in the bladder until the patient voids. After the eighth day the suprapubic tube is clamped; after the patient voids for twenty-four hours with the tube clamped, the tube is removed.

REPORT OF ILLUSTRATIVE CASE

A woman aged 67 came to the clinic complaining of hematuria of several weeks' duration. A cystoscopy was done and a specimen for biopsy was obtained. Pathologic examination of the tissue removed revealed epidermoid carcinoma, grade 3. A granular, friable, fungating tumor was found on the left side of the bladder wall near the trigon. It measured about 2 by 2 cm. in diameter. Shortly after cystoscopy the bladder was marsupialized and the fungating bulk of the tumor was removed by an endotherm snare. After adequate anchorage of the bladder wall, intravesical roentgen therapy was begun. The low voltage roentgen treatments were given every other day with a target-skin distance of 3 cm., 0.2 mm. copper filtration, and 60 kilovolts. Twenty-five hundred roentgens was given with each treatment. The time for each of these treatments was twenty-nine minutes. Nine such treatments were administered for a total dosage of 22,500 roentgens. The induration of the bladder wall subsided steadily and at the time of the secondary closure of the bladder, two months after the first operative procedure, no evidence of the tumor could be found. The patient has since been kept under careful supervision and is symptom free except for slight frequency of urination.

SUMMARY

In recent years Schaefer,[1] Witte and Chaoul [2] have developed efficient shock-proof apparatus for low voltage roentgen therapy which can be given at the relatively short target-skin distances of 3 and 5 cm. or, if desired, by actual contact of the tumor with the anode or target that transmits the beam. Chaoul has extended the applicability of this method from accessible cancers, e. g. the oral cavity, the skin and cervix uteri, to cancers of the rectum made accessible by surgical procedures. One of us (G. T. P.) conceived the idea of applying this principle to the treatment of carcinomas of the bladder. The principle of marsupialization of the bladder over an extended time to permit fractionated doses of low voltage x-rays to be applied through intravesical cones is new. Although the experience with this method is necessarily limited and the time after treatment is too short to evaluate its curative value, it seems at this time to offer a distinct improvement over the previous methods of treating carcinomas of the bladder.

CEREBRAL COMPLICATIONS FOLLOWING LIGATION OF THE CAROTID ARTERY

J. L. FETTERMAN, M.D.
AND
W. H. PRITCHARD, M.D.
CLEVELAND

Ligation of the carotid artery has been used over a considerable period as a therapeutic measure for a variety of serious craniocerebral conditions. Originally it was used as an emergency measure in an effort to control severe hemorrhage following lacerations of the great vessels of the neck and head (Pilcher and Thuss [1]). During the middle years of the nineteenth century it was attempted for the purpose of relieving the then incurable cerebral disorders, as for example intense trifacial neuralgia and chronic epilepsy. However, the mortality was high and the permanent residual symptoms of recovered patients serious. Consequently the operation was discarded.

In the past thirty years, with the increasing safety of surgical measures, the procedure has been reintroduced, particularly in the treatment of arteriovenous aneurysms, either anomalous or traumatic (Campbell and Martin,[2] Gutmann [3]). In certain instances ligation of the vessels has been carried out for peritonsillar (Greenfield [4]) and nasal hemorrhage. Frequent cranial trauma leads to occasional arteriovenous communication between the external carotid artery and the cavernous sinus, and the resulting pulsating exophthalmos becomes the most common indication for carotid ligation (Kolodny [5]).

The seriousness of carotid ligation was stressed by Pilcher and Thuss, who concluded from their extensive review of the literature that in from 20 to 25 per cent of patients who survive the operation cerebral complications develop. Matas [6] found but 11 per cent

From the Neuropsychiatric Division, Lakeside Hospital, and the School of Medicine, Western Reserve University.

A preliminary report of this paper was read before the Cleveland Neurologic Society, Wednesday, March 17, 1937.

showing serious cerebral sequelae. Dandy[7] urges caution in this procedure with any patient over 30 years of age.

Recently we have had the opportunity of studying the neurologic complications following such ligation, to observe the clinical course and ultimately to examine the brain post mortem. Our data may be of interest.

REPORT OF CASE

History.—K. L., a man aged 37, was admitted to the wards of Lakeside Hospital in November 1936, because of right hemiplegia of three months' duration. In 1924 he had undergone appendectomy for a gangrenous appendix. At that time also he had had several inches of his ileum removed because of tuberculous enteritis.

The present illness occurred abruptly in February 1936 when a profuse nasal hemorrhage from his left nostril developed during shaving. No known cause for the bleeding could be found. Despite intranasal packing and local applications, the bleeding continued. He was hospitalized, and although he received five transfusions in seven days the hemorrhage continued and his condition became critical. When all other measures had failed and the red blood cell count had fallen to 1,300,000, both the external and the internal carotid arteries on the left side were ligated. Two and a half hours after this procedure flaccid right hemiplegia with difficulty of speech and swallowing was noted.

The clinical course thereafter was that of chronic disease. He was unable to use his arm or leg, he could not express himself, and three months later convulsions developed.

Examination.—At the time of his first admission the patient appeared poorly nourished and apathetic looking. The significant abnormalities were entirely neurologic. There was complete right hemiplegia, with marked spasticity, muscular atrophy and hyperactive reflexes and associated confirmatory signs of involvement of the pyramidal tract. Sensory tests revealed diminution in pain, in temperature and in touch, with astereognosis on the right. There was marked aphasia. The blood pressure was 114 systolic and 64 diastolic, and laboratory tests, including a platelet count and determination of bleeding and of clotting time, gave normal results. Spinal puncture revealed normal fluid with an initial pressure of 120 mm. of water and a total protein value of 23 mg. per hundred cubic centimeters. The visual fields showed partial right homonymous hemianosia, affecting chiefly the lower quadrant.

It was felt that the patient had diffuse left cortical atrophy subsequent to his operation. His treatment was symptomatic, with physical therapy to the affected parts.

He was readmitted to Lakeside Hospital Sept. 13, 1937, because of weakness and loss of weight of four months' duration. He had had no return of function in his extremities, and atrophy of the muscles of the right shoulder girdle had developed. His speech, however, had improved somewhat and his convulsions become less frequent. The physical status on this admission was unchanged, with the exception of observations consistent with general loss of weight. All studies of the blood again gave normal results.

*Encephalographic study performed at this admission by Dr. Claude Beck was recorded as follows by Dr. Eugene Freedman: "The roentgenograms show a tremendous dilatation of the left lateral ventricle, which is approximately four or five times normal" (figs. 1 and 2). The diagnosis was marked atrophy of the left side of the cranium.

A battery of intelligence tests were given by our psychologist, Margaret R. Barnes. The results were as follows:

"Arthur point performance scale: chronologic age adult; mental age 8 years; intelligence quotient 53. Achievement Tests: (1) Metropolitan achievement test (primary I, form A grade equivalent): Word picture 2.1, word recognition 1.5, number concept 2.7. (2) Stanford achievement test (advanced examination form A): arithmetic: computation, educational age 9 years 5 months; grade placement 3.6.

"Comments: The Arthur scale rates the patient as having a low moron grade of feebleminded intelligence. He is handicapped on this test to the extent that some patients speed up their time scores by using both hands. Also he now uses his left hand, whereas he is normally right handed. However he has been using his left hand for about two years and should have reached maximum efficiency by this time.

"The school achievement tests were attempted for some indication of how much of his old learning he had retained. His ability to manipulate verbal concepts is decidedly limited. The word picture test asks that the patient connect the printed word with a picture. This he can do as well as a beginning second grader. The word recognition tests require that the patient pick out from several words very much alike one which is presented orally. This he does as well as a child beginning 1A grade. The third verbal test requires that he underline all the words among several which belong to a given category. He did not fail in this because he did not understand the directions as the trial tests were worked out correctly although with much more difficulty than is ever experienced with the normal first grade child. During the actual test he failed completely. It is interesting to note that with the ascent of probable abstractness of the task the patient failed progressively. The same tendency showed itself in the test of number concepts, although his retention has been better in this than in the verbal field.

"The Stanford achievement test was given first, and it was found that the patient has lost all memory of what the conventional symbols mean. When they were explained, he did computational problems as well as a child beginning 3A grade.

In considering the serious intellectual impairment which this test revealed, it is important to remember that prior to the ligation this patient had been a keen, active, successful business man of at least average intelligence.

Course.—Several months later a serious intestinal ailment developed, characterized by nausea, hiccups and diarrhea. The roentgenograms revealed a granulomatous lesion in the colon proved after resection to be tuberculous. He died on his second postoperative day of this condition, which was independent of the major neurologic disorder.

*Postmortem Examination (performed by Dr. C. H. Evans of the Institute of Pathology of Western Reserve University, with neuropathologic study by Dr. A. T. Steegman).—The cause of death as revealed by the autopsy was generalized acute peritonitis, with tuberculous foci in the peritoneum and lungs.

The brain weighed 1,400 Gm. Over the left frontal and parietal lobes an indentation in the cerebral cortex extended 11.5 cm. and averaged 2.5 cm. in width, running parallel and superior to the sylvian fissure and extending anteriorly to a point 3.5 cm. from the median longitudinal fissure. Over the indentation a cystic structure fluctuated with any motion of the organ. Transverse coronal section of the fixed brain (fig. 3) showed the ventricles to be uniformly dilated, but the left lateral ventricle was much larger than the right. An area of necrosis in the distribution of the left external portion of the sylvian artery extended forward almost to the left frontal lobe and involved three frontal convolutions; posteriorly it extended to the occipital lobe. Both white and gray matter were destroyed, but the cystic structure had not ruptured into the lateral ventricles. The temporal lobe was spared. Part of the outer portion of the caudate nucleus had been destroyed with extension to the external capsule. Posteriorly the region of the supramarginal gyrus was involved, with extension to the intermedial lateral aspect of the occipital cortex.

Degeneration of the secondary nerve tract was evidenced by marked reduction of the superior lateral aspect of the thalamus, the left side of the left peduncle and pons, the left inferior portion of the medulla and the right lateral columns of the upper cervical segment of the cord (fig. 4). In the circle of Willis, the left posterior communicans artery was entirely absent. The right posterior communicans artery was less than 1 mm. in diameter. The vertebral arteries were dilated, and a few atheromatous plaques were present over the intima. The lumen of the left internal carotid artery had been obliterated. The stump of the right showed moderate arteriosclerosis (fig. 5).

COMMENT ON THE OUTSTANDING CLINICAL SYMPTOMS

Personality and Mental Status.—According to the available history the patient had previously been a successful, well adjusted business man, well liked socially and loved at home. After the catastrophe he became moody, morose and irritable. Everything in the household upset him; the playing of his children disturbed him; situations in the home aroused him to outbursts of anger. On one occasion he made a gesture at suicide. In contrast to the difficult behavior at home, for the most part he smiled cheerfully at the hospital, cooperated well and acted pleased with his environment. He made friends with other patients and took cognizance of the activity in the ward. In the course of the neurologic examination he would observe keenly his reflex responses and the success or failure of various tests. At times he would make a gesture of disgust when he failed in certain performances. More frequently, however, he was inclined to ready laughter and appeared easily amused by certain remarks and procedures.

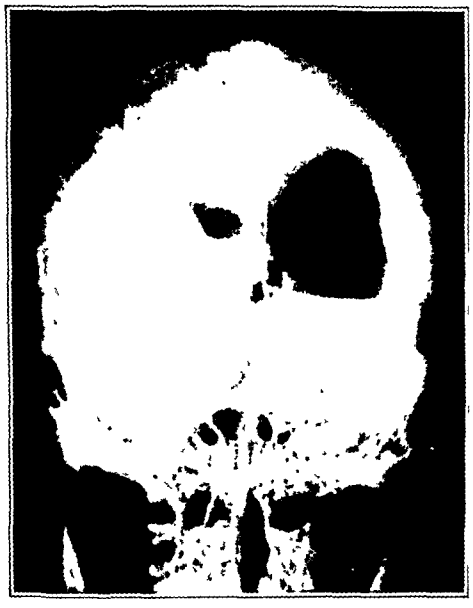

Fig. 1.—Anteroposterior encephalogram showing the tremendous dilatation of the left lateral ventricle, with slight displacement to the left. The picture shows clearly the "hydrocephalus ex vacuo."

Though unable to express himself, inner thinking appeared to harmonize with the situation. His mimicry and gestures were consonant with his apparent understanding of success and failure.

This general behavior would indicate a better mental capacity than was revealed by the intelligence tests. It is likely that these tests, which are dependent on verbalization, yielded a result lower than the deportment and conduct would indicate; also it is possible that emotional responses and cooperation may take place even with serious intellectual impairment.

The contrast between the serious personality disorder manifest at home and the apparently winsome personality in the hospital indicates the profound influence of the environment on behavior. It shows also that the deficit in what is expected may decide the behavior response. At home the patient, though an invalid, was still the head of the house; he could see difficulties and problems, or they were brought to his notice. As head of the house, he was expected to correct and supervise. Unable to perform this function, he would express disgust and explode angrily at the children. Such outbursts were the external evidence of being exasperated with his own helplessness. In the hospital his maximum duty was to take orders and cooperate. As he could perform this duty well, he was looked on as an ideal patient. His ability to perform what was expected evoked self satisfaction and made him a contented patient.

The rather free emotional display referred to as hyperpathy by Schilder [8] has been ascribed to a lesion in the pathways between the frontal lobe and the supramarginal gyrus.

The serious loss of intelligence revealed by the psychologic tests is explained by the total amount of brain tissue damaged plus the fact that the atrophy was in the dominant left hemisphere. As Weisenburg [9] has pointed out, patients who have had cerebral vascular accidents in the left hemisphere show more intellectual loss than those who have suffered a corresponding lesion in the right hemisphere. Apparently that portion of the brain entrusted with the responsibility of speech control has developed a more important intellectual function.

Many of the symptoms of this patient were similar to those in a case reported by Wortis.[10] However, his patient was confused and disoriented.

The Aphasia.—The most serious handicap which this patient presented was his inability to use language as a tool of thought. He would attempt to express himself in response to a question, but at first he would emit a sound which might be translated as "petee peton—petee, peton." Whatever he had intended to say was expressed only by the constant repetition of the words "petee, peton." The exact meaning of these sounds never came to light. The difficulty was not only with speaking; there was a corresponding inability to read and write; for example, if a simple command was written on a card, such as "raise your hand," he would

glance at the letters, run his fingers across them, smile and perhaps utter his usual "petee, peton" but would not understand the order. He was able to see, and did not show a primary visual defect, for he could recognize familiar objects; for example, if he was shown a picture of a street scene or instructed to point to an automobile, a tree or a child, he would do so promptly,

Fig. 3—Coronal section of the brain, showing severe atrophy of the left half with compensatory dilatation of the left lateral ventricle. Severe necrosis can be seen in the lower portion of the cortex at the island of Reil.

correctly and with a joyous expression at his successful performance. Writing was markedly restricted. He was able to write only his own name and a few numbers. Although he showed this serious expressive impairment, the receptive side of speech was better preserved. If he was asked a simple question, he would understand it and reply with a gesture of his head. If a written command, such as "raise your hand," was ignored and then spoken, he would respond quickly.

The preservation of the understanding of the spoken word has an anatomic basis, as can be seen in figure 3. The temporal lobe is little affected. The first temporal convolution (Heschl) is the center for the understanding of the spoken word. The intactness of this convolution in our case may be ascribed to the fact that some blood, sufficient to supply the superior temporal convolution, had reached this region by way of the anterior communicating artery to the middle cerebral artery. Also, as pointed out by Davison, Goodhart and Needles,[11] the function of the temporal convolution may have been maintained through an adequate collateral blood supply by the anastomotic branch of the posterior cerebral artery. Apparently the blood supply to this region was sufficient. The serious loss of the ability to read (alexia) is ascribed to damage of the angular gyrus. The agraphia was probably due to the general cerebral damage.

It may be interesting to point out that though the patient had marked difficulty in understanding words he seemed to enjoy melodies. His chief activity was to listen to the radio, and he would show by gestures that he enjoyed certain familiar arias.

Another explanation for the striking difference between his ability to understand the spoken word and his utter failure to comprehend the written word may be on a learning basis. A child learns the meaning of spoken words early, whereas it is not until the age of 6 years or later that he begins to read. Apparently learning to read is a more complex mechanism and requires a more developed cortex than is present at the age of 1 or 2 years. On the basis of the development it would be logical to expect that certain damage to the brain may cause alexia without producing sensory aphasia. This theory may be appropriate for our problem, though the observation is not uniform in other cases of aphasia. This view is explained in the thesis of Weisenburg[12] "In some patients the relatively simple *expressive mechanism* or receptive function seemed to be more disturbed than the higher and more complicated aspects of the language process." The problem as to whether the difference in the understanding of the written and the spoken word is due to a focal or a mass lesion is reflected in the literature on the subject. The opinion was expressed by Orton[12] that the entire brain is concerned in the production of speech, and he discouraged the tendency to exact localization. This concept was well explained by Schilder, who emphasized the view that function may be the result of the *total action of the brain, whereas a loss of function* may result from a single focal lesion. A homely and simple parallel may be offered in a study of the function of a chain. Obviously the actual pulling power of a chain is dependent on the total action of all the links. Yet the loss of a single link may completely disturb the entire function.

The attempt was made to improve the patient's speech through training, and some progress was made. In the course of months the patient learned to count 1, 2, 3, to pronounced the vowels a, e, i, o, u and to say O. K. However, after having reached this stage in the first six months, he did not achieve further advances. Apparently the amount of brain substance lost could not be compensated for.

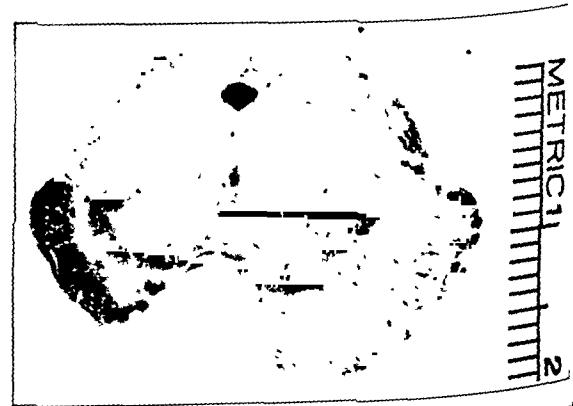

Fig. 4.—Section through the brain stem at the level of the aqueduct of Sylvius. Note the marked asymmetry of the cerebral peduncle secondary to the brain lesion.

The Convulsions.—A third serious symptom was epilepsy. *The patient had never suffered* attacks prior to the ligation but had some six convulsive seizures afterward. As well as one could determine these were generalized, and the patient gave no sign to indicate an aura nor was there a typical sequence, as occurs in jacksonian epilepsy. After treatment was started the patient was given phenobarbital, with a reduction in

12. Orton, S. T.: Some Studies in Language Function, A. Research Nerv. & Ment. Dis., Proc. **13**: 614, 1932.

the number of seizures. The occurrence of epilepsy shows that not one focus but a mass lesion may serve as a trigger area for attacks.

MECHANISM RESPONSIBLE FOR THE CEREBRAL SYMPTOMS

The clinical symptoms are the result of a loss of function of the left cerebral hemisphere, particularly the frontal and parietal lobes, with serious damage to the precentral and postcentral gyri. The involved area receives its blood supply from the middle cerebral artery entirely. We may reasonably conclude that a sudden loss of circulation resulted in cerebral anemia and subsequent encephalomalacia.

Dorrance,[13] in a comprehensive report dealing with ligation of the great vessels of the neck, mentions four possible mechanisms to explain cerebral catastrophes following the procedure:

1. *Anomalies and Variation in the Circle of Willis.*—The occurrence of cerebral anemia from an occlusion of a large vessel raises the question of the integrity of the anastomotic pathways of the circle of Willis. Theoretically one might postulate that, were the collateral blood supply adequate, no such anemia should result. There are many reports in the literature on the frequency of the peculiarities in the makeup of the blood vessel branches that compose this circle. Among 700 cases, Fawcett and Blackford [14] found a complete symmetrical circle in seventy-three, a complete but asymmetrical circle in thirteen and an incomplete circle in four. Windle,[15] among 200 cases, found a complete circle in eighty-three and an incomplete distribution in seventeen. Busse,[16] in the examination of 400 brains, found no instance in which the anterior communicating artery was missing and stated that when the posterior communicating artery was absent it was usually compensated for by other anastomoses. Homans [17] was unable to find in the literature any instance of death following ligation of the carotid artery in which an anomaly of the circle of Willis was present.

Animal experiments tend to show fairly free anastomosis in the brain. Friedemann and Elkeles [18] perfused dye materials through each of four nutrient arteries of the dog's brain while three others were tied and found all parts of the brain uniformly stained. Pilcher and Thuss used differences in arteriovenous oxygen tension to determine the effect of ligation of the great vessels on the cerebral flow of blood in dogs. They found no great differences until both carotid arteries were nearly occluded.

With reference to the intactness of the circle of Willis, it may be stated that the branches are of markedly different size. Whereas there is anatomic continuity between the vessels, the marked angularity and the different caliber of the vessels may be responsible for a reduced flow of blood in certain fractions of the brain; for example, the lumen of the middle cerebral artery appears as a direct continuation of the internal carotid artery. The posterior communicating artery is frequently a narrow vessel joining the middle cerebral artery at right angles. The amount of blood which could enter the large middle cerebral artery may be inadequate, particularly in a person whose effective blood volume has already been seriously reduced by hemorrhage. The volume which could enter the cortical substance, therefore, by a collateral route may not be sufficient, as the circle of Willis resembles a hexagon of vessels of different caliber.

2. *Thrombosis and Embolism.*—Retrograde thrombosis or embolism from the side of ligation is another possibility which has been mentioned. In certain cases

Fig. 5.—The dissected circle of Willis, showing the obliterated lumen of the left internal carotid artery, the thickening of the right internal carotid artery and particularly the absence of the left posterior communicating artery. The basilar artery is larger than usual (compensation).

a progressive advance of a clot along the occluding vessel may be responsible for anemia of the cortex.

3. *Stimulation of the Cervical Sympathetic Trunks.*—Ligation of the common carotid artery necessarily causes stimulation of the vasoconstrictor fibers accompanying this vessel. The possibility also exists that a sudden vasospasm results in cerebral anemia.

4. *Stimulation of the Carotid Sinus.*—Another contributing factor is the disorder resulting from stimulation of the carotid sinus. This area in the bifurcation of the common carotid artery is extremely sensitive to intravascular pressure. Compression of the sinus or a rise in intravascular tension causes vagal impulses which reflexly may produce slowing of the heart rate, fall in blood pressure or direct sinocerebral impulses leading to a reduction in the cortical flow of blood. Stimulation of the carotid sinus in the normal person often leads to sudden syncope (Weiss and Baker [19])

In our case many factors were present, any one or a combination of which may have contributed to the

19. Weiss, Soma, and Baker, J. P.: The Carotid Sinus Reflex in Health and Disease, Medicine **12**: 297 (Sept.) 1933.

serious sequelae of the ligation. These factors include the severe anemia resulting from sustained hemorrhage, the low blood pressure with mild shock prior to operation, the lack of time to perform preoperative compression of the carotid arteries, the absence of the posterior communicating artery on the affected side and the mild arteriosclerosis of the larger cerebral vessels. It is our opinion that the loss of cerebral function resulted from sudden anemia due to tying of the artery, with two causes responsible for the insufficient anastomotic blood supply. The basic defect was structural—the general arteriosclerosis with narrowing of the lumen and the absence of the posterior communicating artery—the contributing physiologic factors were the severe anemia and the low generalized blood pressure.

PRACTICAL SUGGESTIONS

In view of the high immediate mortality and the possibility of serious cerebral complications subsequently, ligation of the carotid arteries constitutes a most hazardous procedure even in the severest forms of nasal hemorrhage. From a neurologic point of view we would emphatically endorse the practice recommended by *Johnson and Foster* [20] and by Strauss,[21] of ligation of the external carotid artery only. They based their procedure in the control of severe intractable nasal hemorrhages on the fact that the major blood supply to the nose comes only from branches of that artery. The small anterior and posterior ethmoid branches of the ophthalmic vessels and perhaps a few slight twigs perforating the cribriform plate come from the internal carotid artery. Thus, from the theoretical standpoint as well as from the neurologic aspect such a procedure promises best results with a minimum of danger. That this point of view is sound may be inferred from Jackson's [22] report of ligation of the external carotid artery in thirty-eight cases, with effective control of hemorrhage and without cerebral complication. In cases of intracranial arteriovenous aneurysm Dorrance and Houdenslager [23] recommended tying of the common carotid artery as a better procedure than ligating the internal. They pointed out that there ultimately may be a collateral supply from the external carotid artery.

CONCLUSIONS

Following ligation of the left external and internal carotid arteries the major symptoms were hemiplegia, hemianesthesia, aphasia, convulsions and impairment of intelligence. The anatomic basis for the symptoms was marked atrophy of the left hemisphere, particularly in the parietal areas and the structures supplied by the middle cerebral artery. For the physiopathologic basis of the cerebral lesion several factors were found, including arteriosclerosis, absence of the posterior communicating artery and severe general anemia prior to ligation.

This case offers strong support to the practical suggestion that in cases of intractable nasal hemorrhage otherwise uncontrollable only the external carotid artery be ligated.

THE CEMENT BURN

ITS ETIOLOGY, PATHOLOGY AND TREATMENT

J. MINTON MEHERIN, M.D.
AND
THEODORE P. SCHOMAKER, M.D.
SAN FRANCISCO

In the past few years the importance of the subject of cement burns has again been forcibly brought to attention as a result of the vast building enterprises that have been undertaken.

In projects that involve the use of large quantities of concrete the medical profession, the employer and the employee are constantly confronted with the problem of the cement or concrete burn.

The lesion is an important one because of the economic loss to the employer and the employee. The literature contains but meager information concerning this type of burn. This is true not only as to its etiology and pathology but likewise as to its treatment, which in some instances is predicated on hazy or even erroneous fundamental chemical principles.

The composition of Portland cement and of concrete is shown in table 1.

It is shown that, in these percentage compositions of cement and concrete, calcium oxide or lime forms by far the major portion of cement, and it is this substance with which we are primarily concerned. When cement is mixed with sand, gravel and water to form concrete, the alkaline reaction is diluted only by the bulk of the other relatively inert substances. As determined colorimetrically,[1] the p_H of these samples of cement in solution varies between 11.5 and 12, which is well on the alkaline side.

areas: (1) an area of inflammation and hyperemia at the periphery and in the depth of the involved tissue; (2) a layer of necrosis which follows the inflammatory action; (3) a layer in which the chemical cauterization results in a solution of the cells already killed by the inflammatory process. These three—hyperemia,

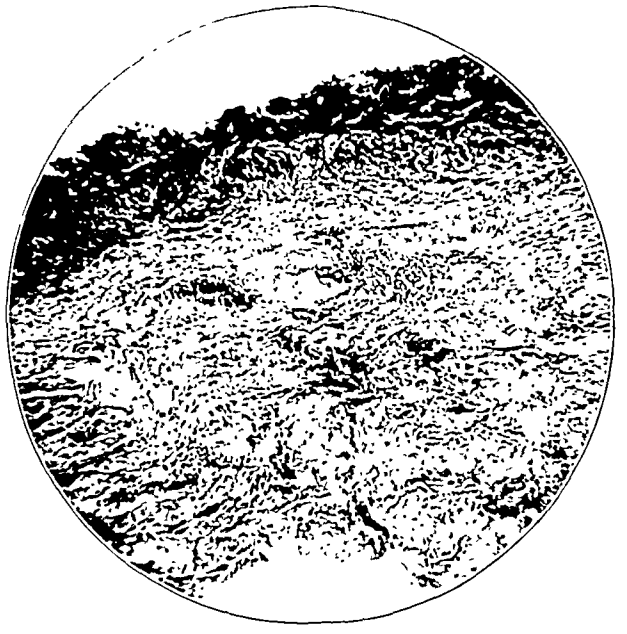

Fig. 2.—Human skin twelve hours after exposure to cement. Slightly reduced from a photomicrograph with a magnification of 80 diameters.

inflammatory necrosis and chemical solution—are to be considered as successive stages of the same action.

A scab is formed after corrosion by the coagulation of the inflammatory exudate and by the chemical products (mostly albuminates) resulting from the interaction of the corrosive agent with this exudate and with killed cells. Alkaline corrosives combine with the tissues to form chiefly alkaline albuminates or with fats to form soaps and in this way produce tissue destruction. These corrosives are very hygroscopic and withdraw water from the cells. This further contributes to the necrosis.

Peculiar to alkalis the scab formed is soft, since the resulting compounds are soluble and thus the chemical readily further penetrates into the tissues, spreading and extending deeply.

In the case of cement we are dealing with five definite factors in the production of the burn:

1. Abrasive action of the concrete.
2. Friction made by wearing apparel and the rubbing of contiguous anatomic parts.
3. Heat of solution while slaking, which, however, is a minor factor.
4. The hygroscopic action of lime with its consequent cellular destruction.
5. Its corrosive action as an alkali. Since the alkaline albuminates are soluble in the alkalis, they are redissolved and reprecipitated so that destruction continues until the alkali is dissipated. In contradistinction, acid burns are practically self limiting, since the acid albuminates formed are insoluble in acids.

The pathologic picture of the cement or concrete burn is clearly shown in the accompanying illustrations. These biopsies were made at intervals of approximately twelve, forty-eight and seventy-two hours after the patient had been burned with concrete.

In figure 1, twelve hours after exposure to concrete, one sees a loss of epithelium down to the corium with some edema of the subcutaneous fibrous tissue. A portion of normal skin is also shown.

Figure 2, a higher magnification of figure 1, shows the marked cellular infiltration about a sweat gland. Note the extent of the subcutaneous edema even after

TABLE 1.—*Definitions or Composition of Portland Cement and of Concrete*

Portland cement:	
Silica (SiO_2)	22 %
Alumina (Al_2O_3)	7½ %
Iron oxide (Fe_2O_3)	2½ %
Lime (CaO)	62 %
Magnesia (MgO)	2½ %
Sulfur trioxide	1½ %
Loss on ignition	2 %
Concrete (all proportions are by weight):	
Sand	29 %
Gravel	55 %
Water	8 %
Cement	8 %

so short a time. There is one area of round cells around a hair follicle, but most of the infiltration follows along the sweat glands to their bases.

The epithelium, which has been destroyed down to the corium, has been replaced by a pseudodiphtheritic membrane in which are found inclusions of amorphous substances, supposedly calcium.

Figure 3 is a still higher magnification of figure 1, showing the necrotic pseudomembrane with amorphous

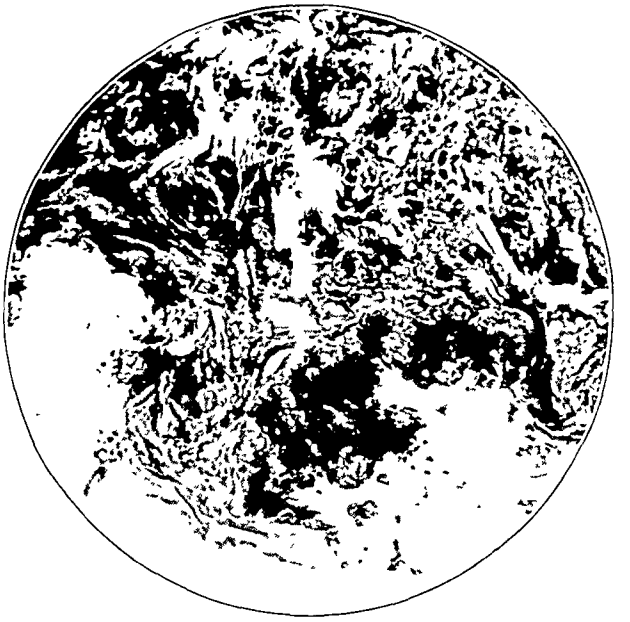

Fig. 3.—Human skin twelve hours after exposure to cement. Slightly reduced from a photomicrograph with a magnification of 450 diameters.

material on the surface and needle-like crystals extending into the necrotic tissue.

Figure 4 shows the formation of a bleb beneath the pseudodiphtheritic membrane, approximately two days after exposure to concrete. The necrosis is extending deeper into the corium and there is a small abscess about a sweat gland.

Figure 5 shows the effect of concrete on human skin three days after exposure. Note how the necrosis has spread so that it now extends into the subcutaneous tissue. The black isolated and conglomerate areas to

the left are calcium deposits. Note the depth at which these lie and the halos of necrosis about them. To the right the calcium deposits with their areas of necrosis can be seen extending into the subcutaneous tissues.

Figure 6 is a higher magnification of a portion of figure 5, showing these amorphous calcium deposits surrounded by necrosing round cell infiltration. We

Fig. 4.—Human skin two days after exposure to cement. Slightly reduced from a photomicrograph with a magnification of 15 diameters.

believe from their location and configuration that these deposits are probably in the sweat glands.

Figure 7 is an oil immersion view of the calcium deposits deep in the tissues.

ANALYSIS OF CASES

In a period of approximately a year and a half sixty cement burns have come under our care. These cases are analyzed in table 2.

It is seen that a relatively long interval elapses between the onset of symptoms and the time of application for medical treatment. The symptom that eventually brings patients with this condition to the doctor's office is pain. This latent period in the manifestation of pain is typical of burns even from concentrated alkalis. Once the caustic action has begun, the persistence of pain is likewise typical of these burns.

The usual site of such cement burns is the dorsum of the feet, the malleoli, the popliteal spaces, the wrists, the hands and the contiguous surfaces of the fingers. Since cement workers usually wear high boots and gloves, such burns occur most frequently at the sites of friction, proving that the abrasive action of the concrete is by no means a negligible factor in the production of the lime burn.

Attention is called to the relatively high incidence of infections (20 per cent) complicating cement burns. The time that elapses between the onset of symptoms and the application for treatment apparently plays no part in deciding ultimately whether infection will take place or not.

It is a well known fact that a common cause of disability among cement workers is furunculosis, far outranking all the other disabling cutaneous diseases in this industry. Such infections are caused primarily by a clogging of the sweat glands with lime. Dust, body débris and bacteria are then rubbed into the sweat glands, secondarily producing an infection. An ideal culture medium for such bacteria located deep within the sweat glands is furnished by the products resulting from the corrosive action.

As a result of the warmth furnished by the bandaging of such burned areas and as a result of the sweating that takes place beneath these bandages, it is not unusual to have furuncles develop in neighboring hair

TABLE 2.—*Analysis of Sixty Cases*

Number of cases	60
Average interval between onset of symptoms and application for medical treatment (longest interval 7 days, shortest 8 hours)	3 days
Disability	642 days
Average per case	10 days
Treatment period	857 days
Average per case	14 days
Number of cases requiring hospitalization	7
Average stay in hospital per case	8 days
Percentage of total cases requiring hospitalization	11
Number hospitalized due to infection	6
Number of cases infected	13
Percentage of total cases infected	20

follicles while the patient is under treatment. Particularly is this true when the bandage is held in place by the ill advised use of adhesive plaster against the skin in the dressing of such wounds.

TREATMENT

Such burns are preventable, but it is difficult to preach prophylaxis to employers other than on a dollars

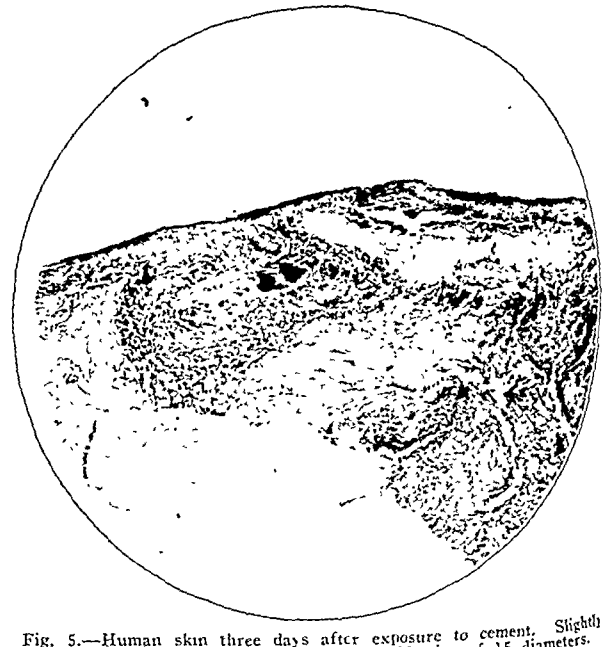

Fig. 5.—Human skin three days after exposure to cement. Slightly reduced from a photomicrograph with a magnification of 15 diameters.

and cents basis. The sixty cement burns that we have treated in the past year and a half involved a total loss of time of 642 working days with an average disability of ten days per case. The average total cost per case approximated $50.

Smearing of the parts most frequently exposed with petrolatum has been shown by experience to be somewhat unpractical though effective. It is especially effective when the dry cement is being handled. Clean

dry boots and gloves, frequently changed, reduce considerably the morbidity caused by these lesions.

The installation of showers and compulsory bathing by men coming off a shift would be most desirable. Such lavage would abort many of the cases entirely, and in those cases in which corrosion has already started it would greatly decrease the depth and extent

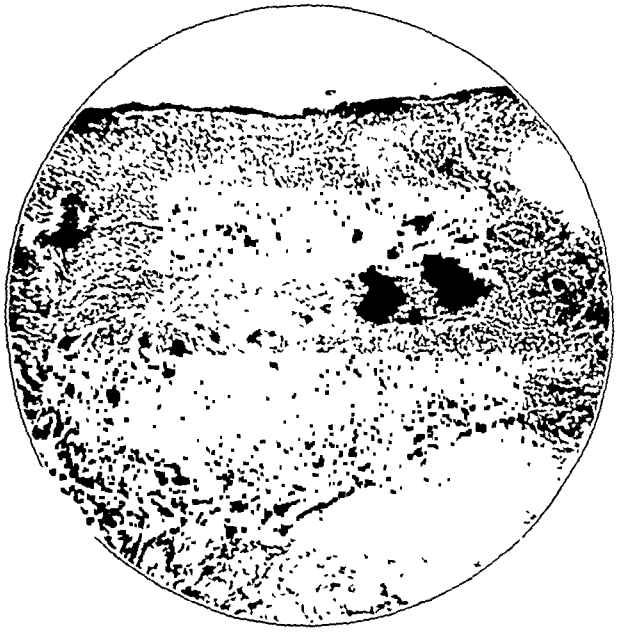

Fig. 6.—Human skin three days after exposure to cement. Slightly reduced from a photomicrograph with a magnification of 80 diameters

of the burn and probably call the lesion immediately to the patient's attention.

After the symptoms have begun to manifest themselves one would imagine the ideal immediate treatment to be the chemical neutralization of the offending agent. Ample proof to the contrary is furnished by the experimental work of Davidson.[3]

One lower extremity of a group of rats was exposed to both strong acids and strong alkalis. In control rats untreated after exposure typical corrosive burns shortly developed at the exposed site, with loss of function of the extremity, and the rats died. Others treated by chemical neutralization shared the same fate, the clinical picture and course of the burn differing only slightly from those which were untreated. Possibly the heat of chemical neutralization is as damaging to the tissues as is the irritant action of the offending agent.

A third group of rats similarly exposed to acids and alkalis were simply treated by thorough lavage with water. These animals showed a minimum of gross pathologic changes. No disability of the extremity ensued and all survived.

The first requisite for immediate treatment then is lavage with water. Practically, however, this principle is not applicable except prophylactically. By the time these patients present themselves to the surgeon an elastic grayish brown crust has already formed, covering an ulceration varying in extent and depth depending on the quantity of cement to which the skin has been exposed. By the third day, when these cases are usually first seen, this scab is extremely tenacious and firmly adherent to the underlying tissue.

3. Davidson, E. D.: The Treatment of Acid and Alkali Burns, Ann Surg. 85: 481 (April) 1927.

Even after an elapsed interval of three days, necrosis undoubtedly continues further, as shown in figure 5. Theoretically it would be desirable to cleanse the burned areas by vigorous scrubbing in order to remove the collection of cellular débris, coagulated serum and cement which constitute the scab. This is not practical since the necrosed areas, though isolated and usually not covering an area greater in size than 2 square inches, are in most cases multiple. Such mechanical scrubbing, however desirable, would require general anesthesia even in the case of small single burns, since infiltration with a local anesthetic in such potentially infected areas is contraindicated. We have tried topical application of procaine hydrochloride, cocaine and the like but have found them ineffective, since these solutions do not penetrate the scab.

These lesions are not amenable to the tannic acid, gentian violet or silver nitrate treatment which has been so generally applied to the thermal burn. In would be undesirable to seal over such areas with a crust not only because of the danger of infection but also because the offending chemicals would be further sealed in the tissues. Serious toxic symptoms have not developed in our cases, since the burned areas, though multiple, did not cover large areas.

The application of a soothing ointment usually loosens the crusts within twenty-four hours, leaving a fairly clean, ragged ulcer. In truth, at the time that such cases come to our notice we are confronted not so much with a burn as we are with an acute ulcer.

Further treatment following removal of the scab then involves the treatment of a simple, acute ulcer, provided

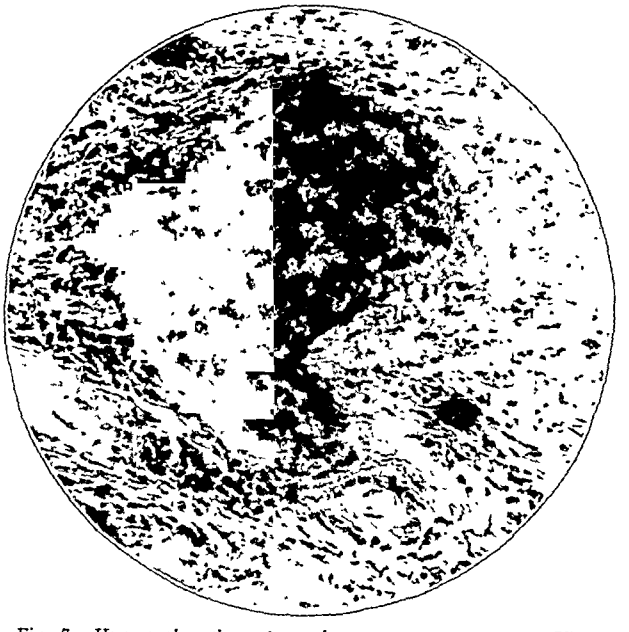

Fig. 7.—Human skin three days after exposure to cement. Slightly reduced from a photomicrograph with a magnification of 960 diameters.

infection does not supervene. Once clean granulations appear, the use of cod liver oil in an ointment has proved satisfactory.

CONCLUSIONS

1. Cement burns are theoretically preventable.
2. Sixty cement burns were treated in the past year and a half, resulting in a loss of 642 working days.
3. Cement burns differ markedly from thermal and acid burns from the standpoint of the symptoms,

pathologic changes and treatment in that the alkaline albuminates are soluble in the alkalis and are thus redissolved and reprecipitated; the chemical meanwhile penetrates and extends deeply into the tissues until it is entirely dissipated.

4. In 20 per cent of our cases infection developed, showing a marked susceptibility to this complicating factor in such lesions.

5. After the removal of the thick, tenacious crust, further treatment involves the care of the resulting simple acute ulcer.

6. Prophylaxis consists in thorough lavage of the exposed parts with water immediately following exposure to cement or concrete and the smearing of the frequently involved parts with a heavy petrolatum ointment.

CYSTITIS FOLLICULARIS

WITH A DISCUSSION OF THE OTHER PROLIFERATIVE LESIONS OF THE BLADDER AND REPORT OF FOUR CASES

W. CALHOUN STIRLING, M.D.

WASHINGTON, D. C.

Among the more rare types of inflammatory lesions in the chronic cystitis group is the proliferative lesion which presents sufficient vesical manifestation to warrant a careful report of the cystoscopic and microscopic observations. It is of general clinical interest, owing to the fact that hematuria is so outstanding.

CLASSIFICATION

In cystitis follicularis the mucosa of the bladder is studded with nodules of various sizes, containing lymph follicles with germinal centers. Hinman and his associates [1] gave an excellent description of these proliferative lesions and divided them into six groups: granular, glandular, follicular, cystic and emphysematous cystitis and bullous edema. Prior to this classification little attempt had been made to group properly these unusual lesions of the bladder. Livermore,[2] quoting White and Martin, classified these epithelial cysts clinically as large and small. He reported a case in which the cyst had assumed a rather large size. Despite Hinman's [1] broad classification, some present day writers are still prone to group these lesions under confusing headings. Redewill [3] expressed the belief that many lesions formerly diagnosed as bullous edema and cystitis cystica were minute gas cysts, i. e. cystitis emphysematosa. Levin [4] reported a case of gas cysts in the bladder resulting from Bacillus welchii in a diabetic patient. Sanes and Doroshow [5] reported two cases of similar involvement, one that of a diabetic person. In all of these cases of gas cysts Bacillus coli was found, and Nowicki [6] said this organism is the cause of cystitis emphysematosa. Paschkis [7] was one of the first to point out that pyelitis follicularis and pyelitis granulosa were separate disease entities. He described two types, the first containing actual lymph nodes with all their characteristics and the second showing aggregations of round cells of inflammatory origin. (Having made similar observations in two of my cases, I can substantiate this point.) Zuckerkandl [8] also described a true and a false type. In the former the lymph follicles are rounded, the peripheral cells being closely crowded together in rows with typical germinal centers. The second form is cystitis pseudofollicularis, with no germinal centers and the cellular arrangement widely distributed and showing no palisading of cells at the periphery. Colonel Ash and I recently saw some specimens removed at biopsy in a case in which a diagnosis of malignant growth of the bladder had been made elsewhere, and our study showed a histologic picture not unlike that of cystitis pseudofollicularis. Several nodules were observed in the mucosa of the bladder and on biopsy were seen to contain a large number of lymphocytes, with no evidence of the typical cellular arrangement of cystitis follicularis or of germinal centers.

Another and more destructive form of cystitis is the gangrenous type, characterized by total destruction of the mucosa of the bladder. Two cases of this type were observed and reported by Hopkins and me [9] in 1934.

This study comprises four cases of proliferative lesions of the bladder, in the first one of which there

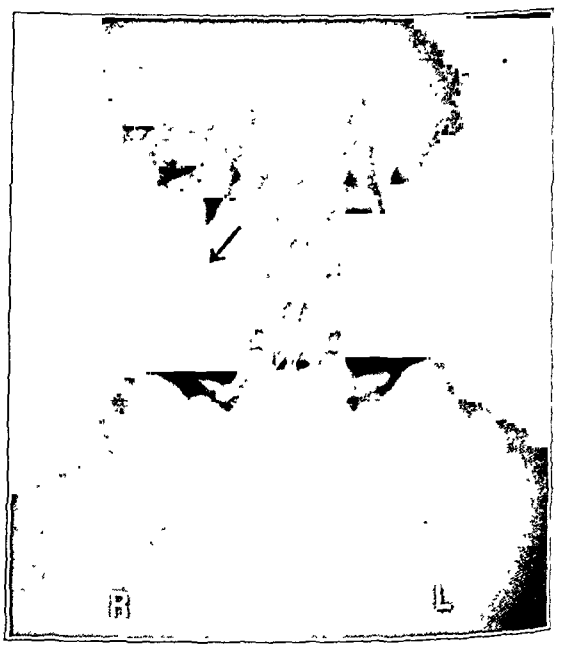

Fig. 1 (case 1).—Intravenous urogram showing a filling defect below the right ureteropelvic junction. This was a constant observation on every pyelogram. A nest of gallstones appears just above and lateral to the upper right calix.

was a unique histologic picture of cystitis follicularis, cystitis cystica and cystitis glandularis concomitant with pyelo-ureterocystitis follicularis. The second case was one of primary cystitis follicularis without apparent involvement of the kidneys or ureters. (These observations, to my mind, refute the statement of Baetzner [10]

Drs. Ash, Cajigas and Jarman gave valuable assistance in the study of the cases reported.

that the process is always initiated in the renal pelvis and extends downward through the ureters to the bladder.) The third case presents an interesting histologic study of lesions of the bladder, in that cystitis follicularis and cystitis glandularis were found present in the same specimen. The fourth was an instance of cystitis granulosa simulating a vesical neoplasm.

Fig. 2 (case 1). Cystoscopic appearance of the bladder, showing the distribution of the nodules in cystitis follicularis. Just below the left ureteral orifice is seen the larger nodule (A) representing cystitis cystica.

In 1913 Kretschmer [11] reported a case of pyelitis follicularis. Hundley and Carson [12] in 1929 reported three additional cases. In two of these the diagnosis was made after the kidneys had been removed for tuberculosis, and in the third it was made at necropsy. They mentioned prolonged intermittent hematuria as an outstanding symptom. I have reviewed the literature since that time and have found but ten cases, in all of which diagnosis was made either after the kidney had been removed because of bleeding or at necropsy.

Before Hinman and Cordonnier [13] presented their report in 1935, but little had been written on this subject. Since that time I have been unable to find any reports of similar involvement in the literature. A total of only eleven cases of pyelitis follicularis are on record. Loewenhardt [14] and Kretschmer [11] were the first to report single cases of cystitis follicularis. In 1935 Hinman and Cordonnier [13] reported five cases in which the diagnosis was made from specimens removed for biopsy from the mucosa of the bladder. This made a total of eight cases of proved cystitis follicularis on record. In the cases reported by Loewenhardt,[14] Kretschmer [11] and Hundley and Carson,[12] in which the bladder was involved, similar lesions were seen also in the kidneys.

ETIOLOGY

The cause of this type of lymphoid hyperplasia of the bladder is still unknown, although it is probably the result of a long-standing infection. Loewenhardt [14] mentioned syphilis as a factor, whereas Baetzner [10] expressed the belief that typhoid is responsible in some cases. Von Frisch [15] expressed the opinion that gonorrhea must be considered. Symmers [16] described their formation as a response of the tissues to a toxic irritant and cited tuberculosis as a good example of toxic lymphoid hyperplasia. None of these diseases were present, however, in my four cases. The colon bacillus was found in urine from the bladder in all of the cases reported in the literature and was also present in my cases. Alexander [17] mentioned cystitis resulting from stone, from stricture and from tuberculosis as capable of producing lymphoid tissue in the bladder. Other observers have found similar lesions in the renal pelvis after the removal of a stone. Cystitis granulosa is seen more often than any other proliferative lesion and is the result of a long-standing irritation of the bladder.

SYMPTOMS

Disturbance of urination is the only characteristic symptom observed in this condition. Frequency, urgency or burning on urination is present, and pain over the bladder is constant. The vesical tenesmus is as severe as that seen in tuberculosis or interstitial cystitis. Massive hematuria has been a symptom in all but one of the cases of pyelitis follicularis, as well as in most of those of cystitis emphysematosa reported, but was present in only one of the cases of cystitis follicularis reported by Hinman.[1] It was present in but two of my cases, one in which the renal pelvis and ureters were involved and the other the case of cystitis granulosa which had become ulcerated.

Pain in the costovertebral angle and bilateral ureteral pain simulating the passage of blood clots was observed in one case. Women are more prone to this condition than men (6 to 1), owing probably to the frequency of cystitis in women. It occurs during every decade, though most often during the fourth.

Fig. 3 (case 1).—Bilateral retrograde pyelogram showing the same filling defect in the right ureter as seen in figure 1. These defects are indicated by the arrow. Other filling defects may be noted in the lower part of the right ureter, as indicated by the smaller arrows. Marked ureterectasis is present in the middle third.

DIAGNOSIS

Cystitis follicularis cannot always be differentiated from the other proliferative types of cystitis clinically, and the possibility of two distinct lesions of a similar etiologic background in the same patient must always

be considered. Mills [18] said: "Cystitis cystica and granulosa have been confused both clinically and as viewed through the cystoscope. Lautenschlager reported a case as cystitis emphysematosa which later proved to be cystitis granulosa at necropsy." Redewill [3] said that air cystograms are helpful in detecting the presence of general emphysema of the wall of the bladder. The

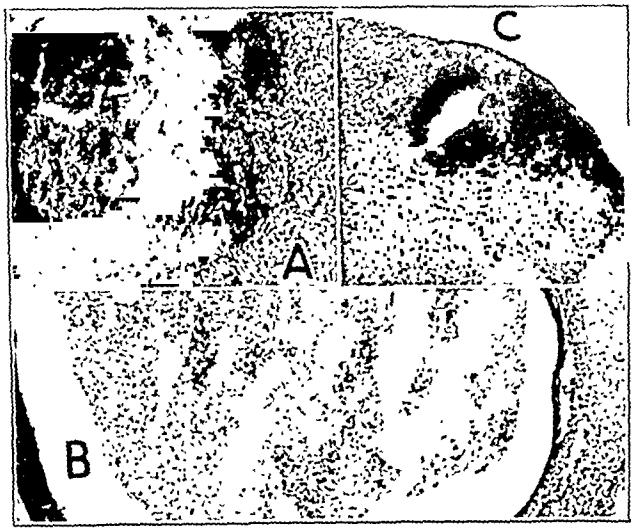

Fig. 4.—Sections showing cystitis follicularis (*A*), cystitis cystica (*B*) and cystitis glandularis (*C*) in the same biopsy specimen. This represents the atypical nodule (*A*) seen in figure 2 (× 70).

final diagnosis must obviously rest on an examination of the specimen removed for biopsy. Cystoscopic examination in cystitis follicularis shows the mucosa of the bladder covered with nodules of varying size, rather closely packed together and of a red-grayish color. They are firm on pressure, whereas in cystitis cystica they are more uneven in size and appear translucent. Cystitis glandularis, on the other hand, rarely presents a distinct cystoscopic picture. The gas filled cysts in cystitis emphysematosa are more translucent than those filled with fluid, and the nodules can be seen best if the bladder is only partially filled with fluid, the nodules appearing in bas-relief. Cystitis granulosa and cystitis polyposa are more easily recognized, owing to the "cluster-like" arrangement of the granulation tissue. Ulceration may occur, as happened in my case, and thus simulate a new growth in the bladder. Newformed capillaries are prominent throughout the loose areolar tissue.

REPORT OF CASES

I wish to analyze briefly four of my cases:

CASE 1.—Mrs. W. D. H., 35 years of age, admitted to Garfield Hospital on June 1, 1937, complaining of intermittent hematuria and pain in the back, had had painless hematuria lasting one week fourteen years before. No further symptoms were noted until two years later, when a similar attack occurred. Since that time she had had intermittent attacks of pain and hematuria three or four times each year. May 31, 1937, the patient had a severe attack of bleeding, with pain on urination and passage of large clots of blood. She consulted her family physician at this time and was sent to the hospital, where she was seen by me for the first time.

A catheterized specimen of urine was grossly bloody, with a large number of clots. A complete study of the blood was done, revealing a moderate degree of anemia with a nonprotein nitrogen content of 65 mg. per hundred cubic centimeters of blood. No blood dyscrasia was present. After evacuation of many blood clots, cystoscopic examination revealed blood coming from the right ureteral orifice. The capacity of the bladder was found to be 400 cc. Urine from the right kidney showed many red and a few white blood cells, and culture showed Staphylococcus albus anhaemolyticus and Staphylococcus aureus anhaemolyticus. The left kidney showed a few white blood cells and an occasional red blood cell. Culture revealed Staphylococcus aureus anhaemolyticus. Intravenously administered indigo carmine was recovered in normal concentration from both sides, with a slight delay on the right. A retrograde pyelogram of the right kidney showed none of the skiodan in the renal pelvis but did show marked dilatation of the upper part of the right ureter. Intravenous pyelographic study was done later and showed some filling defects in the wall of the upper part of the ureter on the right side. A nest of gallstones appeared just above the superior calix (fig. 1). These stones produced so much biliary colic that a cholecystectomy became necessary and was successfully performed.

A second cystoscopic examination November 12 was more satisfactory, as the bleeding had stopped. The entire mucosa of the bladder (fig. 2) was covered by numerous nodules from 1 to 3 mm. in diameter. They were solid and more numerous on the posterior wall. The mucous membrane showed generalized capillary injection. About 1 cm. below and mesial to each ureteral orifice was a group of nodules, different in appearance from those previously described. These were larger, opaque and whitish. Cultures of material from each kidney were negative, although culture of material from the bladder revealed the colon bacillus. The nonprotein nitrogen content of the blood at this time was 45 mg. per hundred cubic centimeters. An intravenous test of renal function was done, with normal appearance time and output on both sides. A retrograde pyelogram (fig. 3) showed moderate pyelectasis on the right side, with marked dilatation and tortuosity of the right ureter. There was some kinking of the ureter just below the right ureteropelvic junction, with a constant filling defect in this area, suggestive of a solitary lymph follicle. Other filling defects were noted in the wall of the lower part of the right ureter. A pyelogram of the left side was normal. The upper part of the ureter, however, appeared slightly irregular.

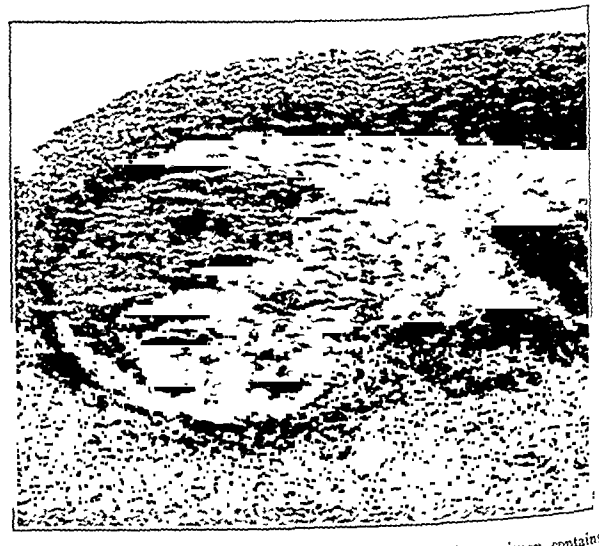

Fig. 5 (case 1).—Section of a typical nodule. This specimen contains four lymphoid follicles; × 75.

The atypical nodule (fig. 4) located 1 cm. below and medial to the left ureteral orifice revealed a large cystlike area covered with intact epithelium. Adjacent to the cyst were a solitary lymph follicle and a gland lined with columnar epithelium. The stroma was made up of densely packed deeply stained small lymphocytes. The center of the nodule appeared less densely packed, with much lighter staining young lymphocytes resembling the typical germinal center seen in the

18. Mills, R. G.: Cystitis Emphysematosa, J. Urol. 24: 217-231 (Sept.) 1930.

lymphatic structures. Examination of one of the typical nodules (fig. 5), which were numerous, revealed four distinct lymphoid follicles, all of which were covered by mucous membrane. None of these showed evidence of ulceration. The diagnosis was cystitis follicularis associated with cystitis cystica and cystitis glandularis (Col J E. Ash and Dr. Tomas Cajigas).

CASE 2.—Mrs. B. A., aged 40, first seen Dec. 21, 1937, complaining of frequency, urgency and burning on urination,

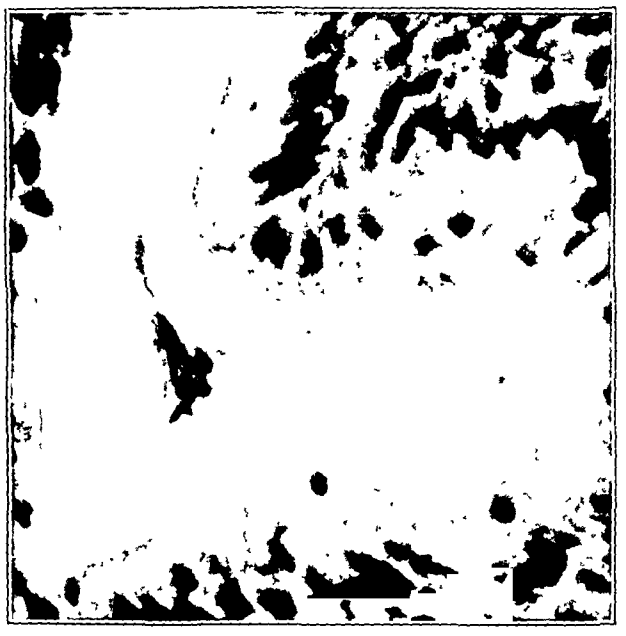

FIG. 6.—High power enlargement of a typical gland lined by columnar epithelium. The gland is filled with mucus and degenerated leukocytes.

had undergone myomectomy for uterine bleeding in October 1937. A month later she began having pain and burning on urination, which had continued to the time of examination. She had not passed any blood in the urine, had had no previous similar attacks and had entirely recovered from the operation. The menstrual history was normal, and she had never been pregnant. The past history was irrelevant. An excretory pyelogram showed a normal concentration of the dye in each kidney, with no abnormalities. The ureters were well outlined, and no cystic changes were seen in the walls of the ureters. The function of the kidneys was equal and within normal limits.

Complete study of the blood, including a Wassermann test and a determination of nonprotein nitrogen, showed no abnormality.

A catheterized specimen of urine showed Bacillus coli in pure culture, with an occasional pus or red blood cell. The capacity of the bladder was 360 cc.

Cystoscopic examination revealed several small cysts in the vesical orifice, extending well around the circumference. They appeared solid and reddish. They did not give the typical cystoscopic picture of cystitis cystica but did resemble the follicular lesions seen in the first case. The entire trigon was covered with a large number of small solid nodules. There was an area of leukoplakia just medial to the left ureteral orifice. The rest of the bladder was congested but showed no nodules. No evidence of bleeding or ulceration was noted. The clinical diagnosis was cystitis follicularis. Biopsy confirmed the cystoscopic diagnosis. The remaining nodules were destroyed by fulguration, including those situated in the vesical orifice. It was believed that all the cysts were thus destroyed.

A microscopic examination of the removed nodule showed it to be covered with transitional epithelium, under which there were two lymph follicles supported by loose connective tissue of moderate vascularity. The germinal centers showed moderate hyperplasia. No evidence of malignancy was noted. The diagnosis was cystitis follicularis (Capt. Elbert DeCoursey).

CASE 3.—Mrs. N. B., aged 48, white, admitted to Georgetown Hospital Sept. 7, 1938, complained of severe pain in the region of the bladder, with frequency and urgency on urination. The present attack had begun about six weeks before, with severe pain over the region of the bladder at the end of urination. The symptoms increased in severity until she was voiding every thirty minutes during the twenty-four hours. No blood was passed and no previous similar attacks had been experienced. Her general health, weight and appetite were normal.

A catheterized specimen of urine contained many pus and a few red blood cells. Cultures showed Bacillus coli of the Aerobacter strain. A preliminary roentgenogram gave negative results, as did routine study of the blood. An intravenous pyelogram showed the upper part of the urinary tract to be normal. The cystogram showed many small, irregular defects along the superior margin of the bladder, suggestive of small papillomas (Dr. F. O. Coe).

A cystoscopic examination showed the trigon and posterior wall of the bladder to be covered by discrete rounded reddish nodules from 1 to 3 mm. in diameter. They appeared solid and were not ulcerated. A cystoscopic diagnosis of cystitis follicularis was made. Five nodules removed for microscopic study showed typical lymph follicles with germinal centers. One section of the specimen revealed the presence of two typical glands in addition to the lymph follicles (fig. 6). The diagnosis was cystitis follicularis and cystitis glandularis (Col. J. E. Ash).

CASE 4.—Mrs. L. H., aged 56, seen Nov. 16, 1938, complaining of hematuria and frequent and painful urination, stated that she had had pain in the region of the bladder with the passage of blood clots for four months. The pain was confined to this region and came on at the end of urination. She had nocturia (six or eight times). The bleeding usually

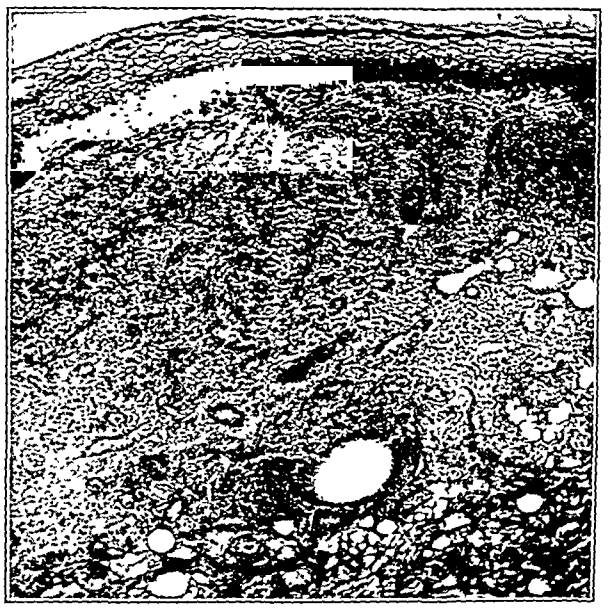

FIG. 7 (case 4).—Section showing cystitis granulosa. There is metaplasia of the vesical epithelium, and the lymph follicles are absent; × 70.

came on at the end of urination and was intermittent, though it had gradually increased in amount during the preceding week. She had not lost any weight and her general health had been excellent. Her past history revealed no similar attack, and aside from the usual diseases of childhood she had not had any severe illness. She had three children living and well and her menstrual history had been normal, including a normal menopause.

A catheterized specimen contained a large number of pus and red blood cells. Culture showed Bacillus coli. A preliminary roentgenogram was normal, as were the results of complete study of the blood. A cystoscopic examination under gas anesthesia on November 21 revealed a circumscribed group of polyps in the trigon; these were approximately 1 cm. in diameter. Ulceration was present and numerous small blood vessels could be seen, one of which was producing the bleeding. The remainder of the bladder was free from any similar lesions, though generalized cystitis was present. A biopsy specimen was taken from the granuloma and on microscopic examination showed metaplasia of the vesical epithelium. The underlying structures consisted of granulation tissue which was fairly vascular, with numerous typical fibroblasts. There was considerable infiltration with lymphoid and pus cells. There was no evidence of malignancy (fig. 7). The whole area was thoroughly fulgurated with a resectoscope. The patient had no further bleeding or pain other than that incidental to the vesical instrumentation. The diagnosis was cystitis granulosa (Drs. Cajigas and Ash).

Summary of Cases of Pyelitis Follicularis

Author	Age	Sex	Chief Complaint	Diagnosis	Cystoscopic Observations	Microscopic Observations	Treatment	Result
1. von Frisch..... (1906)	36	♂	Profuse intermittent hematuria	Pyelitis follicularis	Not stated	Granular pyelitis, solitary follicles	Nephrectomy, left	Cured
2. von Frisch..... (1907)	30	♂	Gross bloody urine	Pyelitis follicularis	Not stated	Pyelonephritis, lymph follicles found in kidney	Nephrectomy, right	Cured
3. von Frisch..... (1907)	37	♀	Bleeding from kidneys	Pyelitis granulosa follicularis	Not stated	Entire kidney degenerated	Nephrectomy, right	Cured
4. Lowenhardt..... ... (1905)	33	♀	Strangury, hematuria, frequency	Pyelitis, cystitis follicularis	Bladder, nodular region, trigon	Nodules in bladder were lymph follicles	Nephrectomy, right	Cured for a time but recurred
5. Taddei..... (1907)	23	♀	Hematuria, four weeks' duration	Pyelitis follicularis	Blood coming from left kidney	Renal pelvis contained many lymph follicles	Nephrectomy, left	Cured
6. Soleri and Zanelli.. ... (1905)	42	♀	Profuse hematuria, frequency, urgency	Pyelitis follicularis	Blood from left kidney, bladder normal	Pelvis filled with sandlike excrescences, lymph follicles	Nephrectomy, left, after cystotomy	Cured
7. Kretschmer..... (1912)	36	♀	Albuminuria, chills, fever, pyuria, frequency of urination	Pyelitis follicularis, pyonephrosis	Pus in right kidney, normal left; bladder normal	Renal pelvis showed lymph follicles with germinal centers	Nephrectomy, left	Cured
8. Stirling..... (1937)	35	♀	Gross hematuria, dysuria, pain, frequency of urination	Pyelo-ureterocystitis follicularis, cystitis cystica	Bladder studded with nodules and cysts	Large number of lymph follicles with germinal centers, also cysts of cystitis cystica	Renal lavage, dilatation of ureter, fulguration of bladder cysts	Improved
9. Baetzner..... (1913)	34	♂	Hematuria, pyuria, pain and burning urination	Pyelo-ureterocystitis follicularis	Many diffuse nodules covering trigon	Nodules containing lymph follicles with germinal centers	Nephrectomy, left	Cured
10. Hundley and Carson... (1923)	40	♀	Hematuria, pain in right side for many years	Pyelitis follicularis, hydronephrosis, hydroureter	Bladder inflamed and ulcerated	Lymphoid hyperplasia of pelvis	Ureteral dilation, renal lavage, nephrectomy on right	Cured
11. Hundley and Carson... (1923)	30	♀	Pain in left kidney, frequency, dysuria, hematuria for several months	Pyelitis follicularis, tuberculosis of kidney suspected	Bladder normal x-ray showed calcareous renal deposit	Kidney contracted, contained many nodules of lymphoid cells	Nephrectomy on left for chronically infected functionless kidney	Cured
12. Hundley and Carson... (1925)	45	♂	Admitted unconscious; no history	Pyelitis, cystitis follicularis	Not performed	Diffuse lymphoid hyperplasia of kidneys, ureters, bladder	....	Died

TREATMENT

Eradication of the long-standing vesical infection, chiefly by the Bacillus coli group, should be attempted by elimination of any focus of infection, such as the teeth, tonsils, gallbladder, colon and rectal crypts. Oral therapy with either sulfanilamide or mandelic acid should be tried. Fulguration of individual nodules has been of value in some cases and was successful in all my cases. Ureteral dilation, renal lavage and the establishment of free drainage are essential. Nephrectomy is usually contraindicated in pyelitis follicularis, as the two renal pelves are similarly affected. Two of my patients have now been symptom free for several months and the third is responding well to similar measures. The fourth patient has been seen recently and has had no recurrence of pain or bleeding. The frequency of urination has also lessened.

COMMENT ON CASES

Whether lymphoid tissue is a normal constituent of the mucosa of the urinary tract remains unsettled, though most writers agree that it may be found occasionally. Ash [19] said "Lymphoid tissue may occasionally be present in the mucosa of the bladder, although it is very uncommon." Ewing [20] stated that "lymphoid tissue is very rare in the normal bladder, but as in all other mucous membranes, mild grades of chronic catarrhal inflammation are often associated with the development of small lymph cell collections. In such cases it is difficult to determine whether such bladders are normal or pathological." He concluded that "well formed lymph follicles with germinal centers are so very rare in the normal bladder that their presence would raise a suspicion of a pathological state." Chiari [21] and Przewoski [22] expressed the opinion that its presence in this location is pathologic. Stoerk [23] was unable to find it in the bladder of the newborn.

Cystitis emphysematosa, cystitis granularis and cystitis cystica, on the other hand, are seen and diagnosed

much more frequently than the follicular type, sixty cases of cystitis cystica having been reported by Morse.[24]

Strachstein[25] found the renal pelvis and ureters involved in two of 3,000 autopsies. It has been suggested that cystitis cystica represents a later stage of cystitis glandularis, owing to rupture and opening of the cysts, and thus accounts for mucus issuing from an organ without mucous glands (Hinman[1]). Giani[26] reported the accidental production of cystitis cystica by introduction of gelatin-coated capsules containing tubercle bacillus into the bladder of rabbits. Other writers ascribed their presence to "cell nests," as described by von Brunn.[27]

Aschoff,[28] Reisman[29] and other early writers said that true glands are not found in the bladder, whereas Zuckerkandl,[8] Ash[10] and Cajigas[30] have found true glandular tissue in the normal bladder, especially in the region of the vesical outlet.

In reviewing the literature on these proliferative lesions, I have not found any mention of the concomitant presence of cystitis cystica, cystitis follicularis and cystitis glandularis. In Kretschmer's[11] case both cystitis follicularis and cystitis glandularis were present. Mills[18] reported a case of cystitis cystica with cystitis emphysematosa. It would not be surprising, however, to find such an association, in view of their supposed common source.

In the first case the diagnosis of pyelo-ureterocystitis follicularis was based on the history of repeated attacks of bilateral renal bleeding, and urographic evidence of filling defects in the kidney and ureter. Cultures of material from both pelves were positive. In the other three cases there was no evidence of renal involvement.

ANALYSIS OF CASES

A critical histologic study of the four cases reported herein as well as the ones reported by other recent writers discloses the fact that in few instances does cystitis present a pure type of lesion. Two or more proliferative lesions may be present simultaneously. Thus the diagnosis would rest on the predominance of a certain type of lesion.

CONCLUSIONS

Four cases of cystitis follicularis were observed. In the first the condition was associated with cystitis cystica and cystitis glandularis, with lesions in the kidneys and ureters. In the second case the picture was uncomplicated, in the third cystitis glandularis was present and in the fourth cystitis granulosa.

The treatment in general should be limited to eradication of foci, oral therapy and cystoscopic destruction of the local lesions. Nephrectomy is usually contraindicated, owing to bilateral involvement of the renal pelves in the pyelitis group. In cases of unexplained hematuria a careful search should be made of the mucosa of the bladder as proliferative cystitis is not as rare as the scarcity of cases would seem to indicate. Biopsy of any suspicious lesion, followed by fulguration, should be the rule.

Clinical Notes, Suggestions and New Instruments

ECHINOCOCCUS CYSTS OF THE LIVER OF FIFTY-SIX YEARS' DURATION

THEODORE C. LAWSON, M.D., OAKLAND, CALIF.

Although echinococcus cysts are not of common occurrence in the United States, they are of sufficient interest always to be considered in the differential diagnosis of tumors of the liver. They grow slowly, but it is not often known for exactly how many years a patient has harbored the parasite. Magnusen[1] has reported a case under observation for forty years, and Holmes[2] reported a case in which the parasite was present for forty-six years. It is rare that one has positive proof of the length of duration of the infestation, and when one has, the case is sufficiently interesting to be worthy of a report.

F. T., a man aged 67, an Englishman, was admitted to the Alameda County Hospital Aug. 2, 1937, complaining of an intermittent pain in the lower dorsal and upper lumbar part of the back and the upper part of the abdomen, which he had had since 1926. At that time he was hospitalized and his condition was attributed to a spinal disorder, and subsequent treatment proved ineffective. Two years before the pain had begun to be more severe in the abdomen than in the back, particularly over the right half of the upper part of the abdomen, radiating into the right flank. This pain was sharp and stabbing, frequently lasting three or four days without remission, with a three or four month interval of complete relief between episodes. Such bouts were so severe that the patient was confined to bed and required from ten days to two weeks for recovery. The pain had no relation to food; he had had no hematemesis, bloody stools, jaundice, flatulence, nausea or vomiting. Constipation had always been troublesome. He had lost about 13 pounds (6 Kg.) in the last two years.

Fig. 1.—The wound, with two small cysts which have just been extruded from the liver.

Prior to entry he had called in his physician, who thought the pain was possibly arising from the right kidney and referred him to a urologist. A pyelogram revealed a normal right kidney, but a mass in the right upper part of the abdomen was palpated and he was referred to the hospital.

The patient was born in England and was a storekeeper by trade. He used considerable alcohol in his youth. He mentioned that he used to swim a good deal in a farming district. In 1882, when he was 11 years old, his abdomen enlarged and he was admitted to St. Bartholemew's Hospital, London, where his abdomen was tapped and his condition diagnosed as "hydatid cyst" of the liver. The abdomen filled again in twenty-four hours, and the next day the cyst was removed surgically. He made a complete recovery. He left England when he was 13.

2. Holmes, H. I.: Hydatid of the Liver of Many Years' Duration, M. J. Australia **1**: 704 (May 25) 1929.

Except for appendicitis, for which an appedectomy was performed in 1933, he had had no other complaints.

Examination showed that the patient was well developed and well nourished. He did not appear acutely ill. The teeth were in poor condition, with gingivitis present. The tonsils were mildly injected. The heart was enlarged and the apex beat palpable in the fifth interspace about 2 cm. outside the midclavicular line. There were occasional extrasystoles. The blood pressure was 128 systolic, 88 diastolic. A nonfixed, tender, discrete mass was felt in the abdomen, presumably the liver, four fingerbreadths below the right costal margin. Below this main mass two other masses were felt, one in the region of the gallbladder, measuring about 10 by 6 cm., and the other just to the left of the midline in the epigastrium, measuring about 6 by 4 cm. Postoperative scars were present in the right upper and the right lower part of the abdomen. The reflexes and the extremities were normal. Proctoscopic examination gave negative results. Examination of the blood showed 80 per cent hemoglobin, 4,420,000 red cells and 10,200 white cells, with 77 per cent polymorphonuclears, 18 per cent small lymphocytes, 1 per cent monocytes and 4 per cent eosinophils. A second count showed 1 per cent eosinophils. The Wassermann reaction was negative. The urine and feces were normal.

A plain roentgenogram of the abdomen showed evidence of an enlarged liver, with some flaky spots of calcification in the right upper quadrant in the region of the liver. Roentgen examination after a barium sulfate enema revealed no intrinsic lesion of the colon. The transverse colon was displaced downward by an enlarged liver. A gastrointestinal series showed the entire second portion of the duodenum to be pushed down and compressed by a large mass, which was palpable in that area and appeared to be continuous with the liver.

Intradermal injection of 0.7 cc. of echinococcus antigen produced an immediate wheal formation, which subsided in six hours.

The preoperative diagnosis was echinococcus cyst of the liver.

The operation was performed Aug. 27, 1937. With the patient under ether anesthesia, the abdomen was opened through an upper right rectus incision. The liver at first appeared to be enormously enlarged, but on closer inspection it was found that it contained a large cyst and that what was left of the liver was stretched tightly over this, the parenchyma being stretched to a thickness of about one-third inch around the circumference of the cyst. On palpation, hydatid fremitus was felt. A cystic

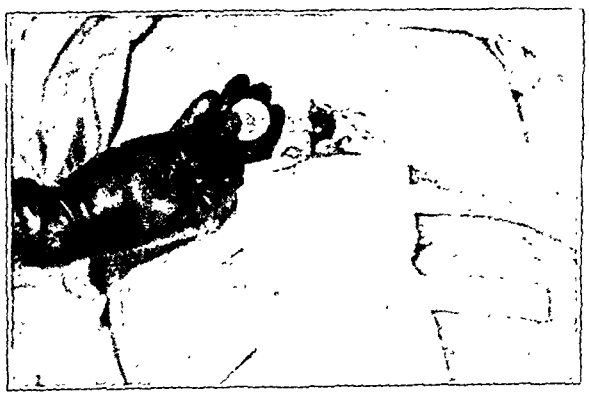

Fig. 2.—The wound, with several cysts being extruded.

mass hanging down from the lower border of the right lobe and a projection of the left lobe downward were the two masses palpated preoperatively. Obviously it was impossible to remove the entire cyst from within the liver. No free fluid was present. The intestine and colon were matted together with numerous though not dense adhesions, and interspersed between the coils were several cysts varying in size from 1 to 5 cm. in diameter. One of the larger of these cysts and the cystic mass attached to the right lobe of the liver were removed. It was impossible to open and drain the liver from its inferior border without spilling its contents within the peritoneal cavity, and, as numerous dense adhesions were felt between the superior-anterior aspect of the right lobe and the dome of the liver to the diaphragm and upper part of the peritoneum, it was thought best to drain the cyst in this area, for it was already extraperitoneal. The peritoneum and fascia were closed, and a new 3 inch incision was made above this incision through the fascia until the dome of the liver was encountered. Two per cent solution of formaldehyde was injected into the hepatic cyst. With an electrocautery the liver shell was punctured through and the opening enlarged to about 3 cm. in diameter. Much clear fluid, numerous collapsed cyst walls and fewer intact cysts were removed. The wound was packed open with gauze, and the patient returned to his bed in good condition.

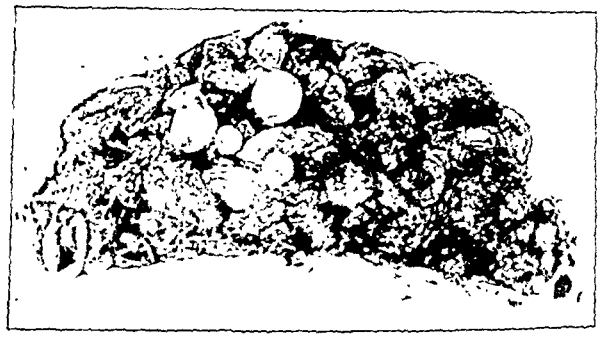

Fig. 3.—The cysts, some collapsed and others intact, immediately after the operation.

The marsupialized wound discharged many cysts and collapsed cyst walls daily. For three weeks the temperature was between 100 and 104 F. The patient appeared to be improving for one week after the operation; he then began to get listless, somnolent and mentally confused, with euphoria, had an increase in pulse rate with a drop in blood pressure, cold clammy sweating and moderate conjunctival icterus and appeared critically ill. A diagnosis of hepatic insufficiency was made, and fluids, including adequate amounts of dextrose and sodium chloride, administered intravenously, were given daily. The recovery thereafter was slow but steady. On the twenty-fifth postoperative day the patient was transferred to Fairmont Hospital for chronically ill patients. He continued to get stronger, ate well and improved. The drainage from the wound lessened, though there was a discharge of one or two cysts on the dressings daily for a month after his transfer, after which no more cysts were expelled and the wound began to granulate in. He left the hospital Thanksgiving day 1937. Subsequent to his return home he gained in weight and strength, was able to return to his occupation as a grocer and had no return of the severe abdominal pains previously complained of. In February 1938 his wound broke open and two cysts were discharged; after three days it healed again. At present he feels well and has no complaints. His incision is firm and nontender and the liver cannot be felt.

The future health of this patient is problematic. It would appear that, since he has harbored the parasite for fifty-six years, he has become partially immunized against it. As he has had time to establish a defensive reaction against the echinococcus he will no doubt continue to exercise it for years to come and will probably succumb to some other causative factor. Death from this parasite is not from a toxic reaction but from complications such as the growth and extension of the cysts into the vital parts of the body by pressure, rupture and secondary infection, with resultant toxemia. This patient has been fortunate in not having an infestation of a vital organ other than the liver, and the reparative powers of the liver are well known. At operation it was judged that only one fifth of the normal amount of hepatic tissue was present. The tissue has probably since regenerated to a greater amount, as evidenced by the clinical improvement to apparently normal health. Mann[3] has shown experimentally, with dogs, that after removal of as much as 70 per cent of the liver the organ is repaired in twelve weeks not only by hypertrophy but by hyperplasia of the remaining hepatic cells. In man the regenerative capacity is probably the same when the cells are normal. The intrahepatic pressure of the slowly enlarging cyst in this case was

3. Mann, Frank C.: The Effects of Complete and of Partial Removal of the Liver, Medicine 6: 419 (Dec.) 1927.

UNIVERSITY OF WASHINGTON
SCHOOL OF NURSING
HARBORVIEW DIVISION.

so great as to leave a shell of hepatic tissue averaging about one third inch, so that the hepatic cells could not have been functioning normally; consequently the regeneration must have been even slower than if they had been normal. The intrahepatic and intracystic pressure gradually increased over a long period; hence the finding that the major portion of the contents of the cyst was ruptured walls of daughter cysts and only a comparatively small portion were intact daughter cysts. Lyon[4] has shown that in cases of hepatic insufficiency, in addition to dextrose given intravenously, dehydrocholic acid given daily by the intravenous route furnishes a distinct support to the liver and hastens the reparative powers of the hepatic and especially of the Kupffer cells. Had it been available it would have been given in this case and no doubt would have hastened the recovery from hepatic insufficiency.

TUBERCULOSIS OF THE MYOCARDIUM

EDWARD W. CUSTER, M.D. AND ROBERT CHARR, M.D.
Assistant Physician and Assistant Pathologist, Respectively, White Haven Sanatorium
WHITE HAVEN, PA.

No organ of the body is safe from infection by tuberculosis, but the relative immunity of muscle tissue in general and heart muscle in particular excites interest and speculation. Although reports of myocardial tuberculosis have appeared in the literature with increasing frequency in recent years, positive proof of the causation is often lacking and the pathologic appearance varies greatly. In the case reported, tubercle bacilli were demonstrated in sufficient numbers to identify the lesion beyond question and the mode of entrance into the heart muscle was clearly not extension from the pericardium in the usual manner. The gross and histologic characteristics were definitely those of tuberculosis.

J. M., a white youth aged 19, was admitted March 3, 1937, to the White Haven Sanatorium in the service of Dr. Edward Bixby of Wilkes-Barre, Pa. Examination revealed extensive

Fig. 1.—Section through mass in wall of right ventricle, showing necrotic center with processes extending into the myocardium. Note that the epicardium and the heart wall just beneath are free from involvement.

bilateral pulmonary tuberculosis complicated by laryngeal tuberculosis. The patient's clinical course was one of continuous regression punctuated by two episodes of severe hemoptysis, the first shortly after admission and the second one month before death. No signs or symptoms of cardiac disease were manifest at any time.

At necropsy the body showed marked pallor and emaciation. There was edema of both ankles, especially the left. The pericardium held 25 cc. of straw-colored fluid containing two small flakes of fibrin. Its inner surface was smooth and glistening and presented no adhesions or other gross evidence of tuberculosis. The heart was normal in size and weighed 300 Gm. Its muscle was pale and soft. The left ventricle measured

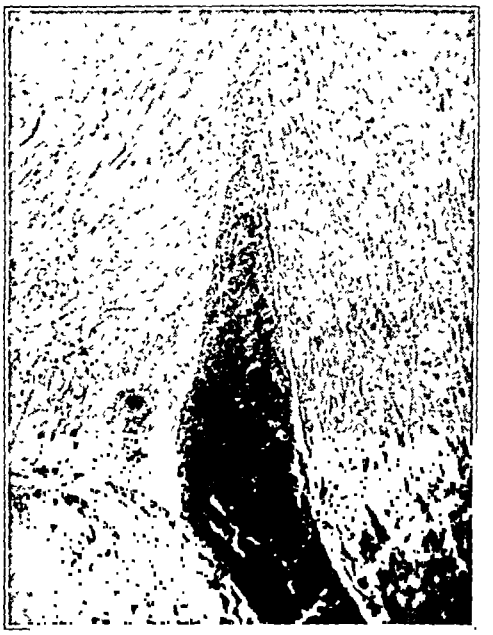

Fig. 2.—Wedge-shaped area of exudate and hemorrhage extending into myocardium. Note the relatively normal muscle tissue immediately adjacent to the inflammation.

1.5 cm. and the right 1 cm. in thickness. The mitral valve was 9 cm. wide, the tricuspid 11 cm., the aortic 7 cm. and the pulmonic 8 cm. When the right ventricle was opened a large round mass, measuring 1.5 cm. across, was seen protruding into the chamber between the trabeculae near the apex (fig. 1). Adjacent to this were four smaller nodules. The large mass had a caseous center with processes extending into the surrounding heart muscle. None of these reached the epicardium, however. The endocardium over the nodules seemed to the naked eye to be intact, although antemortem thrombi were adherent to its surface near the interventricular septum and between the papillary muscles. There was no macroscopic evidence of tuberculosis of the coronary vessels, which were patulous and did not contain clots. No lesions were found elsewhere in the heart.

The pleura was thickened and adherent to the chest wall and diaphragm. On section both lungs showed extensive tuberculosis with cavitation and but slight attempt at fibrosis. There were anthracosis and tuberculosis of the hilar lymph glands but nothing to suggest that the myocardium was directly infected by the disease in the nodes.

Examination of the abdominal organs was not permitted.

Histologic examination revealed that in the center of each nodule was a mass of cellular detritus, and surrounding this area was a zone of small, round endothelial cells. No giant cells were seen. As many as three or four tubercle bacilli to a field were seen in sections from the caseous areas stained by the Ziehl-Neelsen method. The inflammation extended into the adjacent myocardium in the form of finger-like processes parallel to and separating muscle fibers into bundles. There was frequently seen in advance of the exudate a hemorrhagic area which appeared to produce pressure atrophy, and in places complete necrosis, of the muscle fibers. Thus weakened, the myocardial tissue apparently became more susceptible to the advancing disease (fig. 2). The pericardium and subepicardial tissues were normal. The endocardium was broken through by the infection in several places. The most likely portal of entry appeared to be the right coronary artery. Although there

4. Lyon, B. B. V.; Swalm, W. A.; Bartle, H. J., and Sterner, R. F.: The Therapeutic Effectiveness of Dehydrochloric Acid in Liver and Biliary Tract Disease, M. Rec. **139**: 123 (Feb. 7) 1934.

Read before the Laennec Society, Philadelphia, April 26, 1938.

were no tubercles in any of its branches, slight intimal thickening and perivascular infiltration were observed near the caseous masses.

In reviewing the literature we found that a total of sixty-four examples of tuberculosis of the myocardium were found in 14,493 tuberculous patients by different observers reporting large series of cases,[1] an incidence of 0.44 per cent. During the last nine years we have discovered the condition only once in 400 cases in which autopsy was performed. The reason for this relative immunity of the heart muscle remains problematic. The factors responsible in the present case are not clear unless it is assumed that the patient's existence for several weeks in a semimoribund state so lowered his general resistance that the local resistance also was affected.

Clinically, tuberculosis of the myocardium has been diagnosed rarely, although it was suspected in several cases reported by Gouley, Bellet and McMillan[2] in which an ectopic rhythm appeared during the course of known tuberculous pericarditis. Prognostically it is unimportant, as it occurs only with far-advanced disease. There is of course no treatment.

COCCIDIOIDAL GRANULOMA SIMULATING BRAIN TUMOR IN A CHILD OF FOUR YEARS

B. P. Storts, M.D., Tucson, Ariz.

The following case report is of interest because of the relative rarity of coccidioidal granuloma and because it simulated brain tumor.

M. E. H., a girl aged 4 years, first seen Oct. 4, 1937, had been "losing ground" for six months and had had headaches for four months, nausea and vomiting for two months and an unsteady gait for one month. The family history was not important. She had measles at 2 years and a tonsillectomy at 3.

Fig. 1.—Single coccidioidal lesion in right lung.

The headaches had been periodic and mostly frontal. The vomiting had been frequent, usually in the mornings. The unsteadiness of gait, with the child staggering to the left, had grown progressively worse. She had occasional pains in both legs. Mentally she had been alert.

At examination her height was found to be 40 inches (102 cm.) and her weight 31 pounds (14 Kg.). The frontal bosses were prominent and there was a high pitched percussion note over the calvarium. Moderate stiffness of the neck was present. The circumference of the head was 51 cm. There was marked choking of both optic disks. The Romberg sign was present. A roentgenogram of the skull revealed marked widening of all suture lines.

Fig. 2.—Coccidioidal tubercles.

A blood count showed 80 per cent hemoglobin, 4,740,000 red cells and 10,400 white cells. A differential count showed 41 per cent polymorphonuclears, 35 per cent small lymphocytes, 8 per cent monocytes, 1 per cent eosinophils and 15 per cent stab cells. The Mantoux test with 0.1 cc. of a 1:1,000 solution injected intradermally was negative. The sedimentation rate was 48 mm. in sixty minutes. Kolmer and Kahn tests were negative. Examination of the urine and stools gave negative results. A tentative diagnosis of cerebellar tumor, probably a medulloblastoma, was made and the patient referred to Dr. C. W. Rand, Los Angeles.

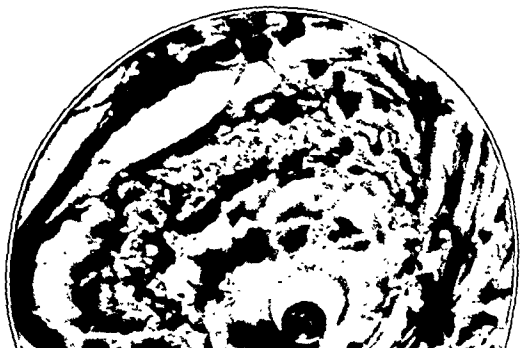

Fig. 3.—Coccidioides immitis in a giant cell.

An exploratory operation by Dr. Rand disclosed a large cyst in the cisterna magna, with thickened arachnoid. Dr. Rand stated that the picture was unusual. The posterior wall of the cisterna magna, which is ordinarily covered by arachnoid

of a spider web transparency, was covered by a white opaque membrane about 1 or 2 mm. thick. This entirely dammed back the spinal fluid and caused a large cyst.

Microscopic studies of the membrane by Dr. C. M. Hyland revealed lymphoid infiltration and numerous concentric masses of cells. The periphery of these concentric masses was composed of dense, almost hyalinized, fibrous tissue, and the center was occupied by a large foreign body giant cell or a group of epithelioid cells. Within the body of the giant cells and in the crevices of some of the epithelioid cells there were spherical bodies with a double contoured highly refractile capsule. The diagnosis was coccidioidal granuloma.

The child was somewhat better for several weeks after the operation. As sulfanilamide has been suggested as a possible cure for this condition, rather large doses were given subcutaneously and intravenously in 0.8 per cent physiologic solution of sodium chloride. However, the course of the disease continued to be hopeless, and the child died December 7.

An autopsy performed by Dr. Ludwig Lindberg revealed a recurrence of the membranous lesion at the base of the brain and the formation of fibrous adhesions to the brain substance. The cerebellum had been pushed down into the area surrounding the foramen magnum. The lower portion of the upper lobe of the right lung contained a small hard nodule consisting of caseous material and simulating a Ghon tubercle. This single, sharply circumscribed nodule, 1.5 cm. in diameter, was the only lesion in the lungs. Sections showed coccidioidal tubercles and Coccidioides immitis.

COMMENT

Coccidioidal granuloma was first described in this country by Rixford in 1895. Afterward many reports appeared, chiefly from California. Recently cases have been reported from other portions of the United States. In California, especially in the San Joaquin Valley, the disease is well known. Dickson [1] described a condition called valley fever and characterized by a cold or bronchopneumonia, often with a relatively high fever and the appearance of painful erythema nodosum. This he said was the primary acute infection with coccidioides. Many writers have stressed the similarity of the disease to tuberculosis. In this instance the similarity is consistent. The disease is rare in children. California [2] reported that since the initial case, in 1895, to July 1, 1936, a total of 450 cases with 224 deaths had occurred. Twenty patients were under 4 years of age and thirty-four under 10. Duckett and Fredeen [3] reported an instance in which coccidioides infection in a boy aged 5 years probably precipitated hydrocephalus and at autopsy extensive meningeal involvement was seen. (This instance would bring the reported total to twenty-two patients under 5.) Rand [4] reported two cases in which the condition in adults simulated tumor of the spinal cord. In one, operation proved beneficial. The treatment is unsatisfactory. Tomlinson and Bancroft [5] expressed the opinion that the use of antimony and potassium tartrate in addition to roentgen therapy is of value. Jacobson [6] emphasized colloidal copper. Surgical excision may prevent spread of the condition.

One wonders why this child should have had a coccidioidal infection. She had lived her entire life in Tucson, Ariz., and her case is the first reported in which the disease originated in this locality. It is of interest that her father maintains a cleaning and pressing establishment and the child frequently rode with him in the delivery wagon, using dirty clothes as a cushion. Mycotic diseases are said to be more common among workers engaged in this type of work.

Special Article

CONFERENCES ON THERAPY

USE OF DRUGS IN THE TREATMENT OF ALLERGIC CONDITIONS

NOTE.—*These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors.*

DR. EUGENE F. DU BOIS: The problems connected with the treatment of allergic conditions are increasing in importance. The question arises whether the advances in therapy have kept pace with the increase in the number of patients. Dr. Gold will start the discussion with a brief outline of the objectives in the treatment of asthma and other allergic conditions.

DR. HARRY GOLD: The rational use of drugs in the treatment of allergic conditions requires that we not merely look at these conditions as clinical entities but focus our attention on the physiologic disturbances which are responsible for the symptoms. At least eight major abnormalities are encountered in cases of bronchial asthma: (1) spasm of the bronchial muscle, (2) hypersecretion of the glands, (3) capillary dilatation, (4) increased permeability of the capillary wall, (5) edema of the mucous membrane and possibly also of the muscle of the bronchi and the bronchioles in the more advanced stages, (6) diminished elasticity of the lungs, (7) emotional unrest, anxiety and nervousness, and (8) asphyxia.

Not all cases present these factors in the same proportions, and it has been doubted whether some of these factors are ever present in some cases. There is a view that bronchial spasm plays but a little role in human bronchial asthma, although in the anaphylaxis of the guinea pig that appears to be the chief factor. The consensus, however, is, I believe, that all these factors, or at least most of them, play some role in most cases of bronchial asthma.

The result of most of these factors is, first, to impair the movement of air through the pulmonary tree and, second, to interfere with the diffusion of gases.

The innervation of the bronchial tree is a matter of some importance and is probably well known to you. Both the vagus and the sympathetic exercise control. The vagus supplies the constrictor fibers to the bronchial muscles and also the secretory fibers to the glands, and the sympathetic supplies fibers which when stimulated relax the smooth muscle of the bronchioles. The sympathetic also supplies the vasoconstrictor fibers and possibly some vasodilator fibers to the blood vessels of the bronchi.

Here is a list of the drugs by classes that are generally employed in the treatment of patients with bronchial asthma as well as other forms of allergic disorders:

1. Epinephrine, ephedrine and other related amines, generally in the form of their salt.
2. Atropine; stramonium.
3. Theophylline preparations, papaverine, nitrites.
4. Calcium salts.

5. Barbital and barbital derivatives, morphine, codeine.
6. Helium.
7. Iodides.
8. Iodized oil.
9. Anesthetics: ether, avertin with amylene hydrate.

The sympathomimetic amines like epinephrine, ephedrine and other related compounds produce effects similar to stimulation of the sympathetics, causing relaxation of the bronchial musculature and constriction of the blood vessels. The members of the belladonna group, atropine and stramonium, block the parasympathetics and thereby reduce the secretions and relax bronchial muscle. Among the agents which act directly on smooth muscle to cause relaxation are theophylline, caffeine, papaverine and the nitrites. The calcium salts reduce capillary permeability. The actions of the general depressants, such as the barbital derivatives, morphine and codeine, are well known. How some of these substances are best put to use in the treatment of bronchial asthma and other allergic conditions will be considered this morning. In the course of the discussions we hope that it may be possible to bring out some of the details of the pharmacologic actions of these compounds.

Dr. Horace S. Baldwin: Bronchial asthma is primarily a functional disorder involving the bronchial tree. When the asthmatic paroxysm is over, the bronchi and lungs return to their previous state. With continued attacks, however, the asthmatic state becomes associated with definite pathologic changes such as emphysema, chronic bronchitis, bronchiectasis, pulmonary arterial hypertension and failure of the right side of the heart. I emphasize these points at the start because, whereas drugs in the treatment of bronchial asthma may for a time give spectacular relief, it is of paramount importance that the fundamental background of sensitivities, respiratory infection and neurogenic factors be carefully studied and adequately handled so that the use of drugs may not be necessary.

From the standpoint of the clinical use of the drugs which Dr. Gold has mentioned, I will proceed according to the outline he gave. Epinephrine, of course, is the drug that gives the most dramatic effect in asthma. It has no effect when given by mouth. When given subcutaneously its effect appears very quickly. I might state here that epinephrine does not usually need to be given in large doses. A dose of 0.25 or 0.5 cc. of a 1 : 1,000 solution of epinephrine hydrochloride is usually adequate. A dose of 1 cc. may often cause considerable tachycardia and nervousness, although it may not affect the asthmatic state any more favorably than 0.25 cc. The drug may be given three or four times a day, sometimes more often if necessary. Solution of epinephrine hydrochloride 1 : 100 may be given by a specially devised vaporizer and inhaled into the trachea. It has to some extent supplanted the administration of solution of epinephrine hydrochloride by hypodermic injection. It is very useful, but we have to beware of the possibility that so much epinephrine taken intratracheally may cause irritation.

Dr. Henry B. Richardson: How long do they inhale it?

Dr. Baldwin: They inhale it until they get a therapeutic effect, which is usually a matter of fifteen or twenty seconds.

In the course of time epinephrine may lose its effect That presents a problem in the treatment of status asthmaticus. I will attempt to touch on it later in the course of my brief remarks.

Ephedrine produces several effects similar to those of epinephrine, and it is potent when given by mouth. The dose of ephedrine is from 0.025 to 0.050 Gm. The effect of ephedrine is less intense and less dramatic than that of epinephrine, but it is very useful in the milder cases of asthma. It may also cause tachycardia nervousness, insomnia and bladder disturbances. In view of this, ephedrine is best given in combination with a sedative, such as phenobarbital or amytal. A useful combination is ephedrine, 0.025 Gm. and phenobarbital 0.03 Gm. In that way the nervous effects of the ephedrine are reduced, whereas the therapeutic effect is not impaired.

We have not been greatly impressed with the value of atropine in asthma. I think the reason is that large doses are needed for therapeutic effect, and these cause disagreeable side effects, with dryness of the mouth visual disturbances and other signs of atropine overdosage.

During the past year we have used theophyllin frequently and we have had some very interesting experiences with it. We give it in the form of aminophyllline. We find that the ordinary oral doses of 0.1 to 0.2 Gm. are not very effective and also that its oral administration in adequate dosage is often complicated by gastrointestinal difficulties. However, when we give it intravenously in doses of from 0.25 to 0.5 Gm. the effects have been very satisfactory. Those individuals in whom epinephrine "fastness" has seemed to develop those in whom epinephrine does not seem to be any longer effective, often secure satisfactory relief in an attack of asthma from aminophylline given intravenously.

The calcium salts have offered attractive theoretical possibilities for the treatment of allergic conditions but I have not been impressed with their value in asthma.

The barbitals find their greatest usefulness in the treatment of the nervous symptoms of the asthmatic patient and in the control of the nervousness caused by epinephrine or ephedrine.

Morphine deserves a very important place in a discussion of this sort. Morphine sulfate to an asthmatic patient in doses of one-eighth grain (0.008 Gm.) or even less by hypodermic injection may be useful. However, it is a very dangerous drug for a good many asthmatic patients. Morphine stimulates the parasympathetic system, and some asthmatic patients are apparently more easily so stimulated by morphine than others. A good many deaths have been due to the indiscriminate use of morphine. The effect of morphine, besides that on the parasympathetic, is to depress the respiratory center and to diminish the ciliary action of the tracheal and bronchial mucous membrane. With too frequent repetition of the dose the patient may drown in his own secretion. I want to emphasize the extreme caution that should be used with the administration of morphine in bronchial asthma. Added to that is the fact that morphine is a habit-producing drug, a real source of danger in the asthmatic patient whose condition tends to recur over a period of years.

Helium offers interesting possibilities, particularly in the treatment of status asthmaticus. A mixture of

ut 75 parts of helium and 25 parts of oxygen is ıter than air, has a greater inherent motility and can breathed with much less effort. It has been used a ·at deal in the Medical Center uptown by Dr. Barach, o developed it. It is particularly applicable in some the very severe cases of status asthmaticus. In this spital, however, where we see a good many cases of ·ere status asthmaticus, we have seldom felt it neces-·y to resort to this method of therapy, which is so pensive. We do however use oxygen alone, pref-ably in the tent, in a good many of these cases. Its e is very important and may be life saving.

Iodides are a very important part of our drug arma-entarium in the treatment of chronic bronchial asthma. ıe bronchial secretion is very tenacious in a great any asthmatic patients. We believe that the favorable fluence of the iodides consists in making the mucus ore liquid and thus facilitating its expectoration. .any proprietary preparations depend for their effect ı the iodides and ephedrine.

The instillation of "iodized oils" is a therapeutic pro-·dure for asthma that is fast losing ground. The more e see it used the more impressed we are with its ıngers, namely localized lipoid pneumonia and the ıronic irritation and chronic infection set up about the ɔint where the iodide in oil remains in the bronchial ·ee.

The various anesthetics, ether and avertin with mylene hydrate are not being used very much. In ɔvere cases of status asthmaticus rectal instillation of qual parts of ether and olive oil, 3 cc. per kilogram of . ody weight, or anesthesia by means of avertin with mylene hydrate, sometimes interrupts a vicious cycle. Their mechanism of action is not understood.

Dr. Du Bois asked me to say something about urti-aria, angioneurotic edema and serum sickness. The lrug treatment for urticaria and angioneurotic edema ·esolves itself into first aid measures while attempts ıre being made to ascertain the etiology. As to these irst aid measures, epinephrine may be given subcu-.aneously in the doses I have indicated. In my experi-ɔnce it is much more effective than ephedrine given by mouth. Calcium therapy given intravenously and by mouth may also be helpful, and when there is low free hydrochloric acid in the stomach the administration of the dilute acid is particularly indicated.

Local measures, such as lukewarm baths of sodium bicarbonate or cornstarch, are also used with benefit.

With regard to serum reactions, one has two phases to consider: The first phase is the matter of anaphy-lactic shock due to the injection of a foreign protein to which the patient may be sensitive. Here prevention is certainly much better than cure, and if adequate cutaneous testing and conjunctival testing are done with the particular serum before it is given, the immediate anaphylactic type of reaction may be avoided. In any case, when a foreign serum is given it is wise to have epinephrine handy in a hypodermic syringe and give it promptly should the symptoms of acute anaphylaxis occur. The second phase is the matter of serum sick-ness occurring usually within ten days to two weeks after the administration of a foreign serum. It is con-trolled in large measure by the same means that we use for the treatment of urticaria and angioneurotic edema. Epinephrine may be given subcutaneously. Ephedrine may be used. Certain calcium compounds may be given intravenously and by mouth. Cool compresses to the itching swollen areas are much better than hot ones.

DR. DU BOIS: How about the use of acetylsalicylic acid?

DR. BALDWIN: Acetylsalicylic acid is a two-edged sword. In serum sickness acetylsalicylic acid may be very useful. On the other hand, you must remember that one of the most common causes of hives and angio-neurotic edema that we generally encounter is acetyl-salicylic acid. If you are going to give it in acute serum sickness it is well not to continue it very long, part-ticularly if the patient continues to have urticaria during its use.

TREATMENT OF ALLERGIC CONDITIONS IN CHILDREN

DR. VERNON W. LIPPARD: We do not use a large number of drugs in treating allergic conditions in chil-dren, and we do not use any that have not been mentioned.

One or two points with regard to dosage might be emphasized. In children we use doses of epinephrine which closely approximate those used in older persons. An effective dose of solution of epinephrine hydro-chloride in an infant is seldom less than 0.1 cc. and most children of school age require doses in the range of 0.3 cc. in order to bring about any therapeutic effect in an asthmatic attack. The ordinary dose of ephedrine sulfate in children is 0.025 Gm. and, as Dr. Baldwin mentioned, we often give a sedative either in the same prescription or concurrently. The use of sedatives might be stressed a little more in relation to children than it has been in adults. Many children become frightened during an asthmatic attack. The attack is likely to subside more quickly if one allays the emotional excitement by liberal use of phenobarbital or other seda-tives in conjunction with epinephrine or ephedrine preparations. We do not use atropine very often because we find, as Dr. Baldwin said, that we cannot give enough atropine to produce therapeutic effects without creating the undesirable toxic effects which accompany large doses.

Of course, we attempt to discover the exciting factors. Since a great many allergic disorders are attributed to hypersensitivity to foods, pollens or inhalants it is often possible to remove the causative factors rather than merely to treat the symptoms. The use of drugs may often be confined to the period when one is study-ing the patient and trying to discover the offending antigens.

DISCUSSION

DR. DU BOIS: The subject is open to general dis-cussion. I hope that you may have many questions relating to the pharmacology and the uses of these drugs, their mode of action, and the relative merits of the different compounds and methods.

DR. MCKEEN CATTELL: I wonder whether Dr. Bald-win can throw any light on the mechanism of the apparent increase in tolerance to epinephrine which sometimes follows the repeated use of the drug. I do not think we observe anything of that sort experi-mentally, although in the case of ephedrine there is an effect we note with repeated administration, which might correspond to something of the sort.

DR. BALDWIN: It is not easy to answer this question. I presume the reason patients become epinephrine

"fast" is that the tissues affected by the epinephrine have become exhausted with continued stimulation.

DR. CATTELL: The definite impression is that it is related to the repeated dosage rather than to any change in the condition of the disease itself?

DR. BALDWIN: The repeated dosage seems to me to be the important thing.

DR. DU BOIS: If bronchial spasm is not an important factor in man, how would this act then?

DR. BALDWIN: Dr. Gold indicated that some observers think that bronchial spasm is not an important factor in the human being. On the other hand edema might well be affected by epinephrine without the effect on the bronchial musculature through the constrictive effect on the bronchial vascular bed.

DR. JANET TRAVELL: You spoke about giving solutions of epinephrine hydrochloride subcutaneously. We know that epinephrine is very poorly absorbed from the subcutaneous tissues, and I wondered whether you ever give the solution intramuscularly.

DR. BALDWIN: We do not usually give solution of epinephrine hydrochloride intramuscularly. We have been under the impression that the intramuscular injection gives too rapid absorption. In cases in which we had given it intramuscularly there occurred severe throbbing, headache and extreme nervousness, which made us reluctant to repeat it. However, I might say that in the treatment of status asthmaticus we do use very small amounts of epinephrine in a solution of dextrose by intravenous infusion, and it seems to be very effective used that way.

DR. GOLD: I wonder whether I may say something about these patients who become tolerant to epinephrine in the course of time and develop status asthmaticus in which epinephrine is no longer useful. When their protracted attack of asthma subsides, they sometimes regain their responsiveness to epinephrine, do they not?

DR. BALDWIN: Yes.

DR. GOLD: Wouldn't this argue against the view that their temporary failure to respond is due to frequent use of epinephrine? Then I should like to ask whether the tolerance may not really be due to the fact that the mechanism of the attack of asthma is different in the late stages of asthma when epinephrine is no longer effective from what it is in the early stages. By way of illustration, if in the early stages it is mainly a matter of bronchial spasm we can overcome it readily, but if in the late stages it becomes more a matter of edema, then epinephrine might readily fail to overcome it. If in the late stages it becomes more a matter of paralysis of the capillary wall, epinephrine would then have as little effect as it has in angioneurotic edema, in which epinephrine is not as effective as it is in asthma.

DR. BALDWIN: This may be true.

DR. GOLD: A change in the disease itself rather than a development of tolerance as the result of the protracted use of the drug would be the formulation that I would suggest to explain the poor response to epinephrine in the late stages of asthma.

DR. TRAVELL: I was going to ask whether there were any other means of prolonging the action of epinephrine besides putting it up in an oily solution?

DR. DU BOIS: Such as rubbing the spot?

DR. BALDWIN: Rubbing of the injected area in the arm with most asthmatic patients is really not very effective. We find it rather a rarity when a patient comes in and says "I rubbed this area after I gave myself the injection and it worked." It is disappointing that it does not work more often.

DR. GOLD: The proposers claim that it works in about 20 per cent of the cases.

DR. BALDWIN: I would say that is liberal.

DR. DU BOIS: I have been disappointed in the method, hoping to demonstrate dramatic effects. I have almost always failed.

DR. ALICE BERNHEIM: Dr. Abramson at Mount Sinai has developed iontophoresis. He finds epinephrine used in that way very effective because that too prolongs the absorption.

DR. GOLD: Dr. Baldwin has spoken about slowing up the absorption of epinephrine by oily solutions in order to prolong the epinephrine action. Are we seeking to delay the absorption or exactly the opposite? When we give a dose of epinephrine subcutaneously for the treatment of asthma we can get effects within two or three minutes, which means that the drug enters the blood stream rapidly. Then, however, a marked local vasoconstriction takes place, which delays or prevents further absorption. An extract of the area of the skin made several hours later by Luckhardt and Koppanyi still contained epinephrine. The problem that needs to be solved is not one of delaying absorption but of accelerating it. Epinephrine delays its own absorption too much. I can readily see how an oily medium might protect the local vessels against the strong constrictor action and in that way prolong absorption. There are other ways in which that might be done. If one irritates the tissues and produces dilatation of the capillaries or paralysis, then epinephrine may continue to be absorbed over a longer period of time. I wonder whether an irritant in the solution of epinephrine might not be a useful expedient. Somewhat more than the 0.1 per cent sodium sulfite used as a preservative might serve the purpose.

DR. LIPPARD: Will Dr. Baldwin please discuss his experience with x-ray therapy in asthma?

DR. BALDWIN: It is a comparatively new method, and it is much too early to attempt a final evaluation. There are some cases of asthma that are helped by exposure of the chest to x-rays, and we usually combine it with irradiation of the sinuses. Some very dramatic results are obtained, and it has seemed to me that the cases helped most often have been the chronic infectious types of asthma with considerable wheezy bronchitis. In others it appears to be of no value. At present we have no definite knowledge of what its effect is on the tissues histologically or what the results will be after five years or more.

DR. WALTER MODELL: If one wants to avoid an increase in blood pressure in the asthmatic patient with hypertension would one use epinephrine or ephedrine?

DR. BALDWIN: In my experience an asthmatic patient with hypertension having an acute attack of asthma may be given epinephrine in small doses. It produces the usual relief of the acute asthmatic attack and the blood pressure is very apt to fall after its administration rather than rise. My preference is to use aminophylline in these cases.

DR. MODELL: How would that compare with the action of ephedrine in the same situation?

DR. BALDWIN: The effect of ephedrine is, of course, slower, but I have not been impressed that the use of ephedrine or epinephrine is harmful to asthmatic patients with hypertension. I would be interested to know what Dr. Gold thinks about that.

DR. GOLD: I cannot say whether or not they would be harmful, but if I had a choice I should use epinephrine instead of ephedrine for the attack of asthma in which hypertension is also a problem. The reason is that ephedrine is rapidly absorbed and epinephrine poorly absorbed. A small part of the dose of epinephrine enters the circulation very quickly, but too little to raise the blood pressure. One way to reduce the vasopressor effect of ephedrine is to give it with epinephrine, because the epinephrine will delay the absorption of the ephedrine.

STUDENT: How do calcium compounds act in relieving the asthmatic attack?

DR. GOLD: I can just state what calcium does that might conceivably be beneficial. It relaxes smooth muscle. This may explain how it relieves renal colic and lead colic. It reduces permeability of capillaries. It also reduces neuromuscular irritability, which is one of the problems in bronchial asthma. It is possible that those three actions would occasionally prove valuable in bronchial asthma.

DR. DU BOIS: If given by mouth, would there be enough calcium to do that?

DR. GOLD: No, it would have to be given by vein, and then the problem of intravenous calcium is one that ought to be considered with circumspection. There is considerable danger in rapid intravenous injection of calcium. A gram or a gram and a half of calcium gluconate in about a 10 per cent solution, injected in a period of from five to ten minutes, not more quickly, may be used.

MR. T. P. ALMY (Student): Would any one comment on or criticize the use of pitressin and a low sodium diet in the treatment of bronchial asthma?

DR. BALDWIN: I have not had any experience with it.

DR. DU BOIS: Suppose you tell us about it.

MR. ALMY: Cook and Stoesser reported in June 1938 six cases in children with bronchial asthma whom they treated with pitressin, a low sodium diet and a high water intake. The use of pitressin was continued for about thirty-six hours. In most cases they obtained some relief, and in some cases it was complete. In one instance the symptoms of asthma returned after the ingestion of 4 Gm. of sodium chloride.

DR. DU BOIS: Are there any comments on that work?

DR. LIPPARD: This work was based on the original observation that diets high in salt increased asthmatic symptoms and that diets low in salt or artificial fever resulted in a decrease in asthma. Cook and Stoesser also studied the effect of potassium chloride, the ingestion of which failed to increase the severity of asthmatic attacks and in some instances seemed to bring about some alleviation. The effects of alterations in electrolyte balance cannot be considered, however, without also considering the water metabolism. It has been shown that administration of pitressin causes not only retention of body water but also an increase in output of sodium chloride. Since the administration of pitressin was effective in decreasing the frequency of asthmatic attacks, despite retention of water, it appears that the loss of sodium chloride is the essential factor.

These studies are interesting from the theoretical point of view but the methods have not been used practically in a large group of patients. They should be of greatest value in diminishing the frequency and duration of attacks rather than in alleviating acute symptoms.

DR. BALDWIN: May I say something more about the use of these drugs we have discussed. We cannot emphasize too strongly that their use constitutes only a part of the treatment of the asthmatic. Those who see asthmatic patients frequently are greatly impressed with the importance of therapeutic measures other than drugs. If you go to the home of a patient who is having an attack of asthma, you should be on the alert for such factors as a feather pillow, a dog sitting on the bed, the cosmetics in use or a sinus infection complicating the asthma. The removal of those factors gives results often more dramatic than the administration of drugs.

DR. LIPPARD: For the benefit of students who have not seen many of these patients, the use of asthma powders should be mentioned. Seldom does one see a child with asthma who has not had some proprietary asthma powder burned in his room. I have been rather impressed with the possibility that the intensity of the attack may be increased by the use of these powders and have never been convinced that they produce relief. The air in a small room in which powders have been burned becomes practically suffocative after a few hours. I do not see how a healthy person could breathe very easily in such an atmosphere.

DR. ADE T MILHORAT: I was wondering whether Dr. Lippard could tell us how he proceeds to give serum to a child who is sensitive. What precautions does he take?

DR. LIPPARD: Serum should be administered only with great caution to children who have histories of asthmatic attacks associated with exposure to animal danders or previous injections of serum. Most fatal reactions have occurred in this group. Both ocular and intracutaneous tests with diluted serum should be performed. If reactions are observed, a small amount of diluted serum may be given subcutaneously in the arm and absorption controlled if necessary by means of a tourniquet. If no generalized reaction occurs within thirty minutes, the remainder of the serum may be given slowly by intravenous injection, preferably diluted 1 : 10. Injection should be interrupted and epinephrine administered at the first sign of a generalized reaction.

DR. GOLD: I should like to ask one question of Dr. Baldwin: whether he feels quite convinced that potassium iodide would be more effective than a strong solution of sodium chloride in bronchial asthma. Is not the expectorant effect of the iodide merely a nonspecific reflex effect of the strong salt?

DR. BALDWIN: I have never used a strong solution of sodium chloride in the treatment of bronchial asthma but I am convinced that either sodium iodide or potassium iodide is a very useful drug in the treatment of chronic bronchial asthma.

DR. GOLD: I do not doubt its being useful. I venture the suspicion, however, that a strong solution of ordinary table salt would be equally effective.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE BOARD OF TRUSTEES REQUESTED THE COUNCIL ON PHARMACY AND CHEMISTRY TO MAKE A STUDY OF THE PROMISCUOUS USE OF BARBITURATES, PARTICULARLY WITH REFERENCE TO THE DANGEROUS USE OF THESE PRODUCTS BY THE PUBLIC. THE COUNCIL INVITED DR. W. E. HAMBOURGER OF WESTERN RESERVE UNIVERSITY TO DRAW UP A REPORT. THE COUNCIL CONSIDERED THIS REPORT AND AUTHORIZED ITS PUBLICATION, EXPRESSING APPRECIATION OF DR. HAMBOURGER'S EXCELLENT WORK. THIS REPORT WILL BE FOLLOWED BY ANOTHER ONE AT A LATER DATE.

PAUL NICHOLAS LEECH, Secretary.

A STUDY OF THE PROMISCUOUS USE OF THE BARBITURATES

THEIR USE IN SUICIDES

W. E. HAMBOURGER, PH.D.

CLEVELAND

At a meeting of the American Medical Association in June 1937 a resolution was introduced on the "Evils from Promiscuous Use of Barbituric Acid and Derivative Drugs," in which was included the following statement: "The evils of these drugs include habit formations, toxic cumulative action, their substitution for alcoholic beverages for drunken episodes, their use for successful as well as unsuccessful suicidal attempts, their improper use being a recognized causative factor in many motor accidents and their improper use being a recognized etiologic factor in some criminal assaults. . . ."

The widespread use of barbiturates is illustrated in table 1 by statistics of the manufacture and sale of the drugs in this country for 1936 compiled by the United States Tariff Commission. These figures were made available through President H. G. Bertram of the Winthrop Chemical Company, in whose opinion, because of the high United States duty, "sales" may be considered practically equivalent to consumption in the United States.

If the average therapeutic hypnotic dose for all the drugs in table 1 is taken as 1½ grains (0.1 Gm.), then the United States sales represent more than 810,000,000 doses a year, which is more than 2,200,000 doses a day. A large part of these drugs undoubtedly were used under medical supervision, often in much larger dosage (for instance, by psychotic patients and for basal anesthesia). What part was used without prescription or medical supervision is difficult to evaluate.

The problem of investigating the promiscuous use of the barbiturates divides itself conveniently into four headings: (1) the incidence of successful suicides by barbiturates, (2) the incidence of nonfatal poisoning, (3) chronic usage and (4) involvement in motor accidents and criminal offenses.

The present report is concerned with the incidence of accomplished suicides. A study of the other aspects is being made and will be reported on at a later date.

SOURCES OF INFORMATION

The data considered in this report come from two general sources: (1) medical literature and (2) vital statistics. The latter were obtained from United States census reports and from data solicited of the Metropolitan Life Insurance Company and medical examiners and coroners of several large cities.

From the Department of Pharmacology, Western Reserve University.

LITERATURE ON SUICIDES AND ACUTE POISONING

The available medical literature on the barbiturates, largely as listed in the *Quarterly Cumulative Index Medicus*, has been examined from January 1926 to July 1938, and the papers significant to the present topic are discussed later. As a rule, data on intentional and unintentional deaths are found intermingled.

The incidence of acute poisoning by barbiturates has increased markedly in recent years. Gillespie[1] in a thorough search of the literature collected 157 reports of published deaths up to the end of 1932, of which forty-four occurred since 1927. The deaths were divided as follows: Fifty-seven were definitely suicidal, thirteen more were questionably suicidal, nine deaths (including three suicides) occurred in addicts, and seven more (including two questionable suicides) were in suspected addicts.

Scarlett and MacNab[2] found a total of 408 deaths in the literature up to the end of 1934. This total represented 247 deaths in the two calendar years 1933-1934 (a discrepancy of four deaths as compared with Gillespie's figures). The great majority of the fatalities in their series were due to suicidal intent, indicating an increasing tendency in this direction from 1932 to 1934, since only one third of Gillespie's deaths were suicides.

In the Registrar-General's statistics for 1931 in England there were 5,149 suicides, of which only thirteen (0.26 per cent) were by barbiturates.[1]

Lowy,[3] analyzing 2,046 replies from hospitals in the United States to questionnaires covering the decade 1924-1934, reported 1,185 cases of barbiturate poisoning with 124 deaths. This includes only the three drugs barbital, phenobarbital and allonal. Some deaths were probably due to the aminopyrine in the allonal. These data may be compared with parallel figures of 139 cases of poisoning and seventeen fatalities by coal tar analgesics (antipyrine, acetophenetidin and acetanilid) and seventy-four cases of poisoning with four fatalities for acetylsalicylic acid. The hospitals had about 2,500,000 admissions a year or 25,000,000 for the decade, so the death rates were therefore approximately as indicated in table 2.

TABLE 1.—*Manufacture and Sale of Barbiturates in United States for 1936*

Drug	Manufacture		Sales	
	Pounds*	Grains†	Pounds*	Grains†
Coal tar barbiturates (essentially phenobarbital)	107,650	755,000,000	98,617	690,000,000
Non-coal tar barbiturates (essentially barbital, amytal, pentobarbital, and so on)	123,517	865,000,000	75,571	529,000,000
Totals	231,167	1,620,000,000	174,188	1,219,000,000

* Weights are avoirdupois; 1 pound = 7,000 grains.
† Value in grains is only approximate.

In Germany, from the end of 1918 to April 1936, Siebert[4] reported a total of 2,894 cases of suicide by solid, liquid and gaseous poisons which he had compiled from publications. Of these, 1,071 were due to barbituric acid derivatives. This is second only to illuminat-

1. Gillespie, R. D.: On Alleged Dangers of Barbiturates, Lancet 1: 337-345 (Feb. 17) 1934.
2. Scarlett, E. P.; and MacNab, D. S.: Poisoning from Phenobarbital, with Report of Fatal Case and Review of Fatalities Previously Reported, Canad. M. A. J. 33: 635-641 (Dec.) 1935.
3. Lowy, Otto: Comparative Study of Habitual Use of Barbiturates and Coal Tar Derivatives as Furnished by Reports from Various Hospitals Throughout the U. S., Canad. M. A. J. 31: 638-641 (Dec.) 1934.

ing gas, with 1,196 deaths. The other hypnotics together account for only 109 successful suicides. Unsuccessful suicides were not recorded. Presumably they exceed the successful cases in number. The actual number of suicides undoubtedly far exceeds the number reported in the literature. The percentage of suicides by barbiturates in Germany is much greater than the corresponding incidence in the United States, at least until recent years. This is presumably because barbiturates were introduced in Germany several years before their introduction in American medicine, and the "fashion" or "suicide cycle" has only recently turned to barbiturates as a means of self destruction in the United States.

TABLE 2.—*Death Rates for Various Drugs*

Drug	Deaths per Million Admissions*
Barbiturates	5 00
Coal tar derivatives ..	0 64
Acetylsalicylic acid..	0 16

* In Lowy's conclusions, these figures are given tenfold too high The figures given here are from part of his summary table and have been verified by direct correspondence with him.

VITAL STATISTICS ON SUICIDES

Those vital statistics which have been considered in this investigation list deaths due to asphyxiant gases (carbon monoxide, automobile exhaust, artificial illuminating gas and the like) separately from deaths due to drugs and poisons, liquid and solid. Since very few data on gases are available, the figures given here for suicides due to poisons refer only to liquid and solid poisons and do not include asphyxiant gases, except as specifically noted.

U. S. Bureau of the Census.[5]—The latest federal report contains statistics for the five year period 1932-1936 inclusive (table 3 A). During this interval there were 634 successful suicides by all barbiturates This may be compared with 27,978 suicides by all poisons, solid, liquid and gaseous (of which 12,892 were due to gases alone). Deaths from all forms of suicide including the foregoing, numbered 96,256. Suicides by all barbiturates for the five year period, therefore, amounted to 4.20 per cent of all solid and liquid drugs (excluding gases), to 4.92 per cent as compared with suicides by poisonous gases only and to 2.26 per cent of all drugs and poisons, gaseous as well as liquid and solid. Barbiturate suicides constitute 0.66 per cent of suicides by all means, drug and otherwise.

The data for this five year period indicate a definite increase in the incidence of suicides by the barbiturates in the more recent years, while the incidence of suicides by poisonous gases has slightly declined. The frequency of suicides by the barbiturates, as compared to suicides from all causes, has more than doubled from 0.42 per cent in 1932 to 0.93 per cent in 1938, to make the five year average 0.66 per cent. Chart 1 shows a similar upward trend for barbiturates as compared to all solid and liquid poisons.

For each year there are listed a number of "accidental" barbiturate deaths almost identical with the number of suicidal deaths. Martland[6] has pointed out that ". . . a considerable number of undoubted suicides often signed out as 'accidental deaths due to overdose of sleeping powders, etc.' will be found classified under accidental deaths by poison." Such inaccuracies, if eliminated, would nearly double the percentage of suicides by barbiturates. The figures already given, therefore, must be considered as minimum values.

There were 171 suicides due to barbiturates in the United States in the year 1936, according to the official U. S. census[5] figures which represent the entire population of the states, District of Columbia, Hawaii, Puerto Rico and the Virgin Islands, an estimated total of 128,500,000. There were also 165 additional deaths due to barbiturates listed under the heading "Accidental, Other or Unidentified." If one assumes that a considerable number of these are suicides, as Martland[6] has suggested, then the probable true number of suicidal deaths caused by barbiturates in 1936 was close to 300.

Judging from the present increasing trend of suicides by the barbiturates, the probable number of suicidal deaths by this method in the United States in 1937 (census data not yet available) may have approached or even exceeded 400.

The Metropolitan Life Insurance Company.[7]—Claims were paid for 4,658 suicides among weekly premium-paying industrial policyholders in the three years 1935 to 1937 inclusive (table 3 B). Of these 680, or 14.6 per cent, were due to drugs and poisons. A barbiturate was specified as the drug used in forty-one cases, representing 6 per cent of all suicides by drugs and 0.88 per cent of suicides from all causes. Specifically barbital was the worst offender, causing eighteen deaths (44 per cent). Next in order came phenobarbital with ten deaths (24.4 per cent), amytal with eight deaths (19.5 per cent) and allonal with three deaths (7.3 per cent; some of these may conceivably have been due to aminopyrine), and neonal and ortal each with one death (2.4 per cent).

6 Martland, H S, chief medical examiner of Essex County (Newark), N J Private communication to the American Medical Association

7. Dublin, L. I., third vice president and statistician of the Metropolitan Life Insurance Company. Private communication to the American Medical Association.

barbiturates; specifically, phenobarbital eleven deaths (40.8 per cent), barbital nine deaths (33.3 per cent), amytal five deaths (18.5 per cent) and allonal and neonal each one death (3.7 per cent).

Medical Examiners and Coroners.—We are indebted to the following thirteen local officers who replied to the questionnaire on the incidence of suicides by barbiturates:

S. R. Gerber, M.D., coroner, Cuyahoga County (Cleveland), Ohio.

T. A. Gonzales, M.D., chief medical examiner, Borough of Manhattan, New York.

T. B. W. Leland, M.D., coroner, city and county of San Francisco.

H. S. Martland, M.D., chief medical examiner, Essex County (Newark), N. J.

L. R. Padberg, M.D., coroner, city of St. Louis.

F. J. Walsh, M.D., coroner, Cook County (Chicago), Ill.

W. H. Watters, M.D., Associate Medical Examiner, Suffolk County (Boston), Mass.

W. J. Brickley, M.D., medical examiner, Northern Division Suffolk County (Boston).

N. H. Angell, magistrate, police court, Townson, Md.

E. DeRoma, M.D., medical examiner, Norfolk County (Walpole), Mass.

J. F. Golden, M.D., medical examiner, Norfolk County (Stoughton), Mass.

C. O. Nelson, M.D., medical examiner, Norfolk County (West Medway), Mass.

R. R. Ryan, M.D., medical examiner, Norfolk County (East Weymouth), Mass.

Of these thirteen replies, those of the first seven officials in the list are used in this analysis. One of the remaining six (Brickley) has been omitted because most of its data are included in another reply (Watters).

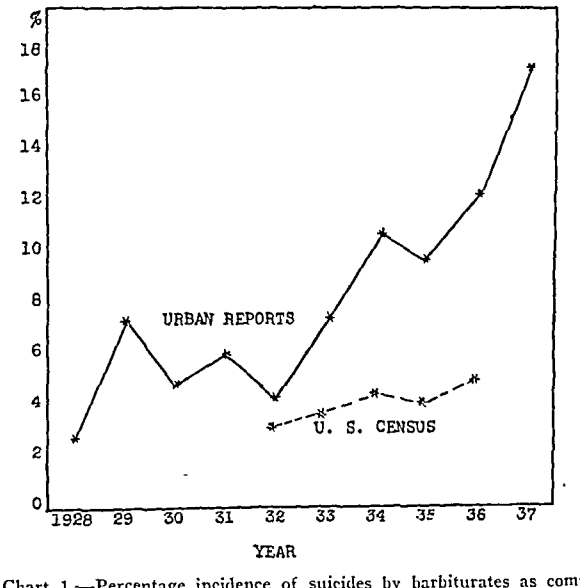

Chart 1.—Percentage incidence of suicides by barbiturates as compared to all solid and liquid poisons.

The last five in the list have been omitted because they do not contain any cases involving barbiturates.

The localities concerned in this report, it will be noted, are mainly the larger cities and their associated counties, namely Boston, Chicago, Cleveland, Newark, New York, St Louis and San Francisco. The period covered is the decade 1928-1937. An additional report for the commonwealth of Massachusetts covering the two years 1936 and 1937 only was also received from Dr. Watters. Although it increases the total number of suicides for those two years, it does not significantly alter the variously calculated percentage values for the urban localities.

A total of 28,965 suicides by all means (table 3 C) was reported. Of these, 4,493 deaths were due to solid and liquid drugs and poisons, exclusive of poisonous

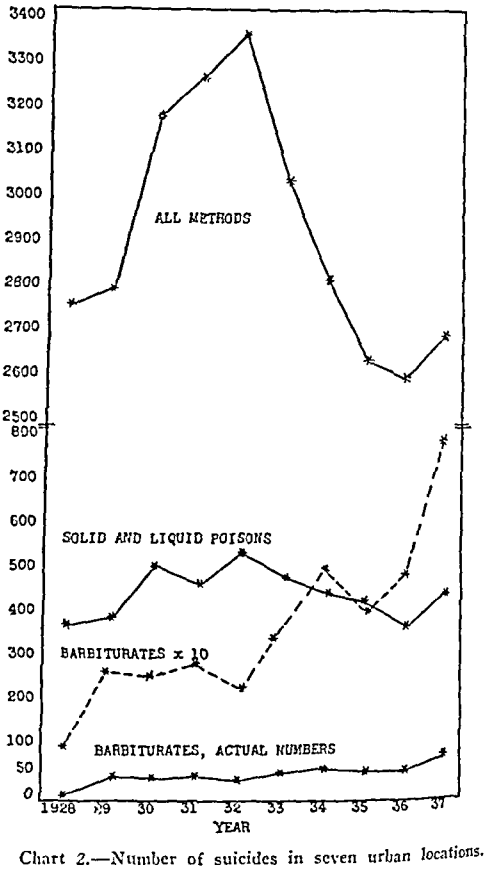

Chart 2.—Number of suicides in seven urban locations.

gases. There were 363 suicides by barbiturates, or 8.1 per cent of the suicides due to all poisons (except gases) and 1.25 per cent of the total suicides by all methods. The percentage of all suicides caused by barbiturates as obtained from this series (1.25 per cent) is nearly double the percentage found in the statistics previously mentioned of the Metropolitan Life Insurance Company (0.88 per cent) and the United States census (0.66 per cent). This indicates a higher incidence of suicide by barbiturates in the population of the larger cities than in the country population, since the last two figures include inhabitants of smaller city and country areas as well as of larger cities.

The percentage of suicides by barbiturates as compared with all poisons (excluding gases), varied widely in different localities from 16.7 per cent in Suffolk County (Boston) to 2 per cent in the municipality of St. Louis. The data for the various regions is given in table 3 C in decreasing order of incidence of suicides by barbiturates.

Six reports, obtained from Boston, Chicago, Cleveland, Newark, New York and St. Louis, listed separately the individual barbituric acid derivatives involved in successful suicides. There was a total of 344 deaths attributable to the barbiturates in this group. Barbital was considered responsible for a majority of 209 deaths (60.7 per cent). Next in descending order came phenobarbital with fifty-six deaths (16.3 per cent), amytal

with twenty-four deaths (7 per cent), allonal with seven deaths (2 per cent), pentobarbital with four deaths (1.2 per cent), ipral, neonal, phanodorn and seconal with one death each (0.3 per cent), and forty deaths (11.6 per cent) due to unidentified or unclassified barbituric acid derivatives. It is plausible that the high incidence of suicides by barbital is somewhat exaggerated and that some of these deaths should also be classified as due to an unidentified barbiturate, since there is a tendency on the part of lay persons, official as well as civil, to call nearly all barbiturates "barbital."

An analysis of the yearly total for the seven large urban areas discloses an upward trend in the frequency of usage of barbiturates as compared both to the total number of suicides and to the number due to solid and liquid poisons. The upward slope of the rise has significantly increased since 1933. This is clearly shown in chart 1, in which the yearly percentage of suicides by the barbiturates as compared with all solid and liquid poisons is graphed. Chart 1 also shows a similar rise, but from a lower level, for the national incidence of suicides by barbiturates as obtained from the U. S. census figures. The two curves clearly indicate the greater use of barbiturates by urban populations than by the national population as a whole (country as well as city).

Another view of the upward trend of the barbiturates as a means of suicide compared to other methods is shown in chart 2. These curves represent in solid lines the actual yearly numbers of suicides by all methods (top curve), by all solid and liquid poisons (middle curve) and by barbiturates (bottom curve). To permit easier comparison, the broken line represents the number of suicides by barbiturates magnified ten times. To conserve space the top curve has been arbitrarily lowered, but the original magnitude of the vertical scale has been maintained. It will be observed that the contour of the curve for barbiturates shows a distinct upward course, increasing since 1933, while there has been a parallel decline since 1933 in both the curves for all poisons and for all methods.

SUMMARY

1. More than 1,200,000,000 grains of barbituric acid derivatives was sold in the United States in 1936.

2. The total number of suicidal deaths by the barbiturates in the United States in 1936 was probably close to 300. The probable number in 1937 may have approached or even exceeded 400.

3. For the five years 1932-1936 the national incidence of suicides by barbiturates represents 4.2 per cent of all poisons (except gases) and 0.66 per cent of all methods used for suicide.

4. In seven large cities and their associated counties, for the decade 1928-1937, barbiturates represent 8.1 per cent of suicides by all solid and liquid poisons and 1.25 per cent of all methods used for successfully committing suicide.

5. The incidence of suicides by barbiturates is nearly twice as high in large cities as in the country as a whole, ranging from 2 per cent in St. Louis up to 16.7 per cent in Boston.

6. The number of suicides by barbiturates has shown a definite upward trend during the past decade, especially marked since 1933, although the frequency of suicides by liquid and solid poisons and of total suicides have both declined since 1933.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

CLAPP'S CHOPPED MIXED GREENS

Manufacturer.—Harold H. Clapp, Inc., Rochester, N. Y.

Description.—Chopped mixed greens containing equal proportions of kale, lettuce and swiss chard. Slightly seasoned with salt.

Manufacture.—Fresh kale, lettuce and swiss chard are cleaned, mixed in equal quantities, and chopped to particles of the desired size. Definite amounts of salt are added, the mixture is heated in an atmosphere of steam and automatically filled into cans, sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 93.6%, total solids 6.4%, ash 1.0%, sodium chloride 0.3%, fat (ether extract) 0.4%, protein (N × 6.25) 1.6%, reducing sugars as invert sugar 0.3%, sucrose (copper reduction method) 0.2%, crude fiber 0.6%, carbohydrates other than crude fiber (by difference) 2.8%, calcium (Ca) 0.078%, phosphorus (P) 0.036%, iron (Fe) 0.002%.

Calories.—0.21 per gram; 6 per ounce.

Vitamins.—The methods of preparation and processing are designed to retain the natural vitamin values to the highest degree consistent with adequate and safe heating processes. Contact of the product with air during processing is avoided as far as possible.

TRIX

Manufacturer.—New Foods, Incorporated, Chicago.

Description.—Puffed white corn grits, coated with cheese flavoring containing coconut oil, process cheese and certified color.

Manufacture.—Selected grades of white corn grits are cooked under steam pressure, slightly dried, passed between rolls under pressure, dried and inflated under high pressure. The expanded product is screened, toasted, coated with a cheese flavoring (a mixture of coconut oil and process cheese) and packed in a moisture-proof bag.

Analysis (submitted by manufacturer).—Moisture 3.3%, total solids 96.7%, ash 2.9%, fat (ether extract) 24.1%, protein (N × 6.25) 10.2%, reducing sugars as dextrose none, sucrose none, crude fiber 1.2%, carbohydrates other than crude fiber (by difference) 58.3%.

Calories.—4.91 per gram; 139 per ounce.

CRADLE BABY BRAND STRAINED AND SEEDLESS GRAPE JAM

Manufacturer.—Glaser, Crandell Company, Chicago.

Description.—Canned strained grape jam sweetened with sucrose. The jam may contain small amounts of added acid and/or pectin.

Manufacture.—Fresh Michigan Concord grapes are inspected, washed, stemmed and sent to the cooking rooms or frozen and stored. The fruit is sieved and the jam is prepared in essentially the same manner as that described for Cradle Baby Brand Strained and Seedless Fig Jam (THE JOURNAL, March 18, 1939, p. 1071).

Analysis (submitted by manufacturer).—Moisture 30.5%, total solids 69.5%, water-insoluble solids 0.4%, water-soluble solids 69.1%, ash 0.3%, protein (N × 6.25) 0.4%, crude fiber 0.2%, carbohydrates other than crude fiber (by difference) 68.0%, acidity 0.6%.

Calories.—2.74 per gram; 78 per ounce.

SATURDAY, APRIL 8, 1939

EXPERIMENTAL RENAL ATROPHY

Recently D. R. Drury [1] of the Department of Physiology, University of Southern California, has described a new method for the production of renal insufficiency of any desired grade in rabbits without the production of pathologic changes in the kidney epithelium. Numerous methods for the production of renal insufficiency in laboratory animals have been devised by previous investigators, such as the administration of nephrotoxins or other bacterial products, exposure to x-rays, surgical removal of one kidney with partial ablation of the other and, more recently, the application of Goldblatt ischemic clamps to the renal arteries. By all these technics, however, necrosis or other pathologic changes are produced in kidney tissue, particularly in rabbits. To avoid such cellular degenerations and to produce a purely quantitative reduction in renal function, Drury placed a loose silk ligature about the left renal artery of baby rabbits (400 Gm.) and allowed this loop to serve as a check to normal kidney growth. Adequate renal function was assured in these rabbits by a compensatory hypertrophy of the right kidney. As soon as the desired stage of dwarfism was demonstrable by palpation of the left kidney, the overgrown right kidney was removed. The animal was now dependent solely on the dwarfed left kidney for its total renal function. Drury regulated the diameter of the loop placed about the left renal artery by tying the silk ligature down on a wire of known diameter. The tie was made snugly but not tightly, so as to avoid crushing or damaging the accompanying artery, and the wire was withdrawn. The artery soon grew up to the size of the loop. Kidney growth was arrested at this stage. After removal of the overgrown right kidney, hypertrophy of the dwarfed left kidney is hindered by the restricted blood flow. By varying the size of the loop, any desired degree of renal dwarfism can be produced by this technic. In his current paper Drury reports dwarf kidneys as small as 20 per cent of the total normal combined kidney weight as well as kidneys of intermediary size varying from 30 to 45 per cent of the combined kidney weight.

The California physiologist found that hypertension is demonstrable in his rabbits submitted to this procedure even before removal of the hypertrophied right kidney. Since the rabbits presumably have fully compensated renal function before this removal, his result suggests an unknown endocrine factor (or "mediator") secreted by the stunted left kidney. The nature of this hypothelial direct or indirect vasopressin has not yet been determined. After removal of the hypertrophied right kidney the hypertension is increased. Effects of ablation of the stunted left kidney at this stage of his operation have not yet been tested.

Among the other suggestive effects of the Drury renal atrophy is loss of appetite and resulting loss of weight in practically all animals depending solely on dwarfed kidney function. Disturbance of the sense of equilibrium and anemia were also frequent. The average hematocrit reading falls to about 25 per cent, as contrasted with approximately 30 per cent in normal rabbits. Hemorrhages are frequently found in the intestinal walls, with an occasional hemorrhage into the eyeball. Hypertension is uniformly accompanied by cardiac hypertrophy. The average heart weight in his hypertension rabbits was about 4 Gm. per kilogram of body weight, as contrasted with 2.35 Gm. per kilogram in normal controls.

Drury's most significant result is his observation that a relatively high degree of hypertension develops in renal atrophy before the removal of the hypertrophied and presumably fully compensating right kidney. Whether or not female rabbits at this stage of his operation would develop eclampsia [2] if allowed to become pregnant has not yet been determined.

MOTOR ACCIDENTS AT NIGHT

Numerous accidents at night on the highways continue to indicate the need of more adequate supervision of traffic. Whereas the enforcement of traffic laws has heretofore been mainly a daytime activity, many cities are now placing policemen on streets to handle traffic during the dark hours. Most motorists obtain their experience and training under daylight conditions; the problems that arise at night have not been sufficiently impressed on drivers, and traffic engineering has not kept pace with the situation.

The fatal motor accident rate at night, on the basis of traffic, is more than three times the accident rate during daylight. Motor vehicle fatalities during the hours of darkness have increased 43 per cent since 1930. The entire increase in traffic deaths in 1937 over those in 1936 resulted from the increase in night accidents. However, the recent emphasis on safe driving at night is producing results. The Committee on Night Accident Hazards of the National Safety Council reports for

2. Dill, L. V., and Erickson, C. C.: Proc. Soc. Exper. Biol. & Med. 39: 362 (Nov.) 1938.

the first six months of 1938 a reduction of 26 per cent in the motor fatalities occurring during dusk and darkness.

In its analysis of the problem the committee finds that eyesight, driving experience and mental attitude are the important factors in the driver himself. He too is responsible for the associated problems of intoxication, speed, fatigue and age. The committee found that 78 per cent of the accidents in which the driver had been drinking occurred between 6 p. m. and 6 a. m. Further studies on intoxication as related to driving accidents are under way. Night driving involves a different technic from day driving because of the difference in visibility and in the reactions of the driver. Motorists should be taught night driving technic in their initial training. Much can be done to eliminate the hazards which are the result of low visibility at night. Highway officials should insist on the best design and maintenance of highways with adequate signs and warnings designed for good visibility at night. An improved type of lighting the highways is being installed in many places throughout the United States. The most common method of lighting the road is by means of headlights. Unfortunately the possibilities in head lamps on cars have not been developed as rapidly as those of other parts of the car. Headlights lose as much as half of their original effectiveness in a short time unless they are kept clean and adjusted. The committee recommends that officials consider the importance of securing adequate visibility for night driving and promote safety through installation of good illumination for heavily traveled and dangerous highways and by installation of flood lights at such hazardous locations as railroad crossings, intersections and special entrances.

Recently the Michigan Highway Department studied the use of reflector buttons on rural highways. Units were spaced 100 feet apart and 8 feet from the edge of the pavement on 80 miles of road between Lansing and Detroit. In the first three months of 1938 there was a reduction of 79 per cent in accidents on this stretch of highway, whereas on a control stretch of highway the reduction was only 19 per cent.

The night pedestrian is susceptible to accidents. Night pedestrian fatalities in Philadelphia increased from 56 per cent of the total number of night fatalities in 1935 to 73 per cent in 1937. In New Jersey in 1936, 67 per cent of the urban pedestrian fatalities and 83 per cent of the rural pedestrian fatalities happened at night. The committee urges that the pedestrian give the motorist every possible opportunity to see him. If it is necessary to walk at night in rural districts the pedestrian should carry a light when practicable and wear light colored clothing. Even carrying a white handkerchief is a considerable aid. Because the pedestrian sees the motor's headlights does not mean that the motorist sees him.

The night limits the speed for safe driving. The National Conference on Street and Highway Safety recently fixed forty-five miles an hour as the prima facie speed limit at night in sections where the corresponding day limit is fifty miles an hour. Lower speeds are necessary in many places. Drivers should lower the speed at night in order to keep their safe stopping distance within the range of clear visibility. Safe driving at night is a challenge to the ingenuity of the driver, who must be alert for every indication of objects ahead or changes in the road.

DOCTOR, HERE'S YOUR BOOK!

Some time has passed since "The Story of San Michele" by Axel Munthe emerged shyly from its publisher's sanctum and began to attract public attention. The widespread enthusiasm with which that romantic tale of medical performances was received seemingly initiated a deluge of works by and about doctors, unique in the history of American publishing. Such works as "An American Doctor's Odyssey" by Victor Heiser, "The Citadel" by Cronin, "Fifty Years a Surgeon" by Robert T. Morris, "Fifty Years a Country Doctor" by William N. Macartney, "The Horse and Buggy Doctor" by Arthur E. Hertzler, "Doctor Bradley Remembers" by Francis Brett Young, the confessions of George Sava, James Harpole and Frederick Loomis, and a whole host of minor novels constitute the main exhibits. Most of these works were important as literary contributions to public understanding of the medical scene.

Most recent to attract public consideration is a somewhat autobiographical work entitled "Doctor, Here's Your Hat" by Dr. Joseph A. Jerger, published by a firm only recently in the general field known as Prentice Hall, Inc. This animated diary had previously appeared in part serially in the *American Magazine* and was digested from that partial publication in the *Reader's Digest*. Its literary qualities need not seriously concern us here. Indeed, from a literary point of view it has attracted little, if any, attention. However, the publisher and the author are apparently not averse to using the machinery of modern journalism to keep the volume in the public eye. Of late much propaganda has been devoted to the promotion of the belief that the headquarters office of the American Medical Association is in complete control of the practice of medicine in this country, dictating who shall act as physicians in the hospitals and exercising a control and restraint never within the prerogatives or the practices of the organization. Apparently in the course of his practice Dr. Jerger has had occasional difficulties with both the medical staffs and the directors of several hospitals in Chicago. From time to time these groups have apparently indicated to him that it would be preferable for him to associate himself elsewhere. In these activities, most of which occurred long before the book was published, each of the hospitals acted independently. Obviously, when such institutions are chartered the

right to control the staff rests with the boards of trustees or directors. Nevertheless, Dr. Jerger and his publishers apparently continue to spread the word that organized medicine barred him from the hospitals and that he is denied their facilities by the American Medical Association. This statement, widely disseminated by press associations, has even been made editorially in some newspapers of good repute. The statement is untrue and without the slightest basis in fact. Amazing, however, is the apparent willingness of newspapers and other agencies of public information to disseminate such charges without attempting to secure verification. The American Medical Association has until now failed to pay the slightest attention either to Dr. Jerger or to his book. According to an interview with Dr. Jerger in the New York *World-Telegram*, a committee of the Chicago Medical Society, entirely independently, requested Dr. Jerger to come before it to explain certain pronouncements which were made by him personally. As far as we know, even here no official action has yet been taken.

In any other matter newspapermen would probably have exercised a reasonable amount of diligence to avoid the possibility of being made the unpaid publicity agents for a publishing venture. In this instance at least they have lent themselves, albeit unwittingly, to aid the dissemination of what is after all not an outstanding literary performance.

Current Comment

THE BRINKLEY CASE

The suit for libel and damages filed by John R. Brinkley against the Editor of *Hygeia* was called in the federal court at Del Rio, Texas, on Wednesday, March 22. A jury consisting largely of residents of the vicinity of Del Rio was impaneled and evidence began to be offered by the plaintiff on the afternoon of the same day. In the course of the trial the plaintiff, Dr. John R. Brinkley, offered in evidence not only his own testimony but that of his associates; also a number of character witnesses. It was the decision of the court that patients would not be allowed to testify as to the results of any procedures performed on them. For the defendant there appeared three experts: Drs. Alfred I. Folsom, Dallas; Benjamin Weems Turner, Houston, and J. Manning Venable, San Antonio; also a chemist of the American Medical Association, Dr. E. W. Schoeffel, Chicago. Furthermore, there were read into the record several depositions containing evidence prepared for a previous suit of a similar character which was dismissed. Among the exhibits offered were most of the pamphlets circulated by the plaintiff and a book concerned with his biography written by Clement Wood and entitled "The Story of a Man." Following the completion of the evidence, which required four full days, attorneys for both sides presented the case to the jury and the instructions were given to the jury by Judge R. J. McMillan. After a consideration of several hours, the jury returned its verdict for the defendant. In a future issue of THE JOURNAL (probably the issue of April 22) and also in *Hygeia* it is proposed to present a complete abstract of the evidence and the instructions of Judge McMillan to the jury.

YELLOW TYPHOID BACILLI

The transformation in the test tube of nonpathogenic flavobacteria into virulent typhoid bacilli, recently alleged by Dresel and his co-workers [1] of Leipzig, Germany, challenges conventional theories of epidemiology in typhoid. Eight years ago, several strains of yellow bacteria were isolated from urinary samples. By repeated "single cell" cultivation of these flavobacteria nonpigmented variants were eventually obtained morphologically, culturally and antigenically identical with standard strains of B. typhosus. Reversing the process, the investigators were able to dissociate from a standard laboratory strain of B. typhosus a yellow variant (Bacterium typhi flavum). More than sixty species of flavobacteria are recognized by American bacteriologists, most of them regarded as common saprophytes in surface waters. Several strains, however, such as Flavobacterium fecale and Flavobacterium esteroaromaticum, have been isolated from the intestinal contents of man or as presumptive contaminants from human necropsy material. Medical bacteriologists of the past have usually disregarded these yellow bacteria as of little clinical interest, since none of the known yellow strains had been shown to be pathogenic for man or lower animals. The conclusion of the Leipzig bacteriologists, however, that some species of flavobacteria are merely disguised forms of Bacillus typhosus may lead to a critical reexamination of the experimental evidence leading to this conclusion.

REPORTS OF OFFICERS AND THE BOARD OF TRUSTEES

In this issue of THE JOURNAL under the Organization Section appear the reports of the officers of the American Medical Association and of the Board of Trustees and of the various Councils and Bureaus which will be presented to the House of Delegates at the next annual session of the Association, to be held in St. Louis May 15-19. These reports constitute a survey of current problems in the field of medical practice and of the activities of the American Medical Association in relationship thereto. Every physician who holds membership in the organization, and particularly Fellows of the American Medical Association, should make a most careful study of this material. The responsibilities now assumed by organized medicine are vital in relationship to the health and welfare of the nation. The determination of the policies of the organization rests with the House of Delegates, which is itself directly representative of the membership. The material will be found of exceeding interest as marking an epoch in the affairs of the American Medical Association.

1. Dresel, E. G., and Graf, Willi: Arch. f. Hyg. u. Bakt. **118**: 153 (No. 3) 1937. Dresel, E. G., and Lôtsch, Herbert, ibid. **120**: 286 (Nos. 4 and 5) 1938.

ORGANIZATION SECTION

REPORTS OF OFFICERS

NOTE.—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion.—Ed

REPORT OF THE SECRETARY

To the Members of the House of Delegates of the American Medical Association

The following annual report of the Secretary is respectfully submitted

MEMBERSHIP AND FELLOWSHIP

A review of the Membership and Fellowship records for the five years from 1934 to 1938 inclusive shows that there has been a constant increase in the number of members as well as in the number of Fellows Official reports of the Secretary submitted to the House of Delegates have included the following figures for each of these five years In 1934 the number of members was 98,041 and the number of Fellows 60,714, in 1935 there were 99,536 members and 61,406 Fellows, in 1936 the members numbered 101,946 and the Fellows 62,997, in 1937 the number of members was 105,460 and the number of Fellows 66,296, in 1938 there were 109,435 members and 68,478 Fellows, and on March 1, 1939, the official membership list carried the names of 112,210 physicians, while the names of 69,468 Fellows were recorded on the Fellowship roster

The figures here presented would seem to refute definitely statements emanating from various sources during these five years designed to indicate that there have been great disaffection in the ranks of the physicians of the United States and great diminution in the support of the profession generally for the established policies of the American Medical Association During these same years, in which significant increases in both membership and Fellowship have been recorded, there has been a tremendous increase in the number of requests for service of various kinds These requests have poured into the offices of the Association from state medical associations, from county and district medical societies, from independent organizations of physicians, from official governmental agencies, from the public press, from officers and members of civic groups and from the general public While it is true that a considerable number of communications critical of the policies of the Association and its constituent and component societies have been received, it is also true that a tremendously larger number of communications have been received from the duly appointed officers of medical societies and other organizations, from hundreds of individual physicians and from many laymen indicating confidence in the medical profession of the United States in its organized capacity and as a profession and expressing appreciation of the efforts that have been made by the American Medical Association to carry out the aims and objects defined in its Constitution and By-Laws and to serve the public interest

MEDICAL ORGANIZATION IN THE STATES

It will be seen from the figures presented in an accompanying table that physicians of 2,058 of the 3,139 counties of the United States are now included in the membership of component county medical societies On March 1, 1939, there were 386 counties in which no organization of physicians has been effected as compared with 397 such counties in 1938 Very considerable progress has been made in promoting the efficiency of the official machinery of a number of constituent state medical associations A larger number of component county medical societies now employ full time secretaries or executive secretaries than ever before, and there can be no doubt that through the employment of full time personnel the work of county medical societies is better organized and more efficiently carried out than otherwise could be done

FIELD WORK AND CORRESPONDENCE

Official representatives of the American Medical Association have attended more meetings of state and county medical societies and have appeared before more lay audiences within the last year than in any preceding year It is not possible to give a

thoroughly dependable estimate of the number of persons that have composed either the professional or the lay audiences addressed by these representatives, but it is believed that the lay audiences have numbered more than 150,000 persons and that audiences composed of physicians have numbered from 25,000 to 40,000. Some constituent state medical associations and some of the larger component county medical societies have maintained speakers' bureaus through which speakers have been provided to address civic groups and student bodies of public schools, colleges and universities. The nation wide radio program of the American Medical Association has been heard by a very large but undetermined number of children in schools and of older persons in their homes.

A veritable mass of correspondence pours into the offices of the Association each day, a large part of which consists of communications from the lay public.

In these several ways the aims and objects of the Association and the nature and scope of its work are brought to the attention of both the profession and the public.

Special Session of the House of Delegates

A special session of the House of Delegates was held in Chicago Sept. 16 and 17, 1938, for the purpose of giving official consideration to the national health program submitted to the National Health Conference held in Washington, D. C., in July of 1938 and to other matters submitted by the Board of Trustees. Copies of the proceedings of this special session have been sent to each member of the House of Delegates in attendance at that session, and an account of the proceedings has been widely distributed among physicians and among the members of legislative bodies and of various other groups.

Annual Conference of Secretaries of Constituent State Medical Associations

The regular Annual Conference of Secretaries of Constituent State Medical Associations was not held in 1938. All state secretaries and the editors of all official journals of state medical associations were invited to attend the special session of the House of Delegates held in Chicago September 16 and 17, and most of the members of these two groups attended that session.

Reports of Delegates to State Associations

It has been most gratifying within recent years to note the completeness of reports submitted by members of this House of Delegates to their constituent state medical associations. In some instances these reports have been published in state medical journals almost immediately after the annual meetings of the House, while in other instances such reports have not been submitted until the meetings of the houses of delegates of the state associations.

There can be little doubt that the members of the Association generally are better informed through the publication of these reports prepared and presented by members of this House of Delegates than they otherwise would be, and their interest in the affairs of the Association and their knowledge of the nature and scope of its activities will be increased and enhanced if such reports are made available to them.

Memorials and Resolutions

Up to the time of the preparation of this report, no memorials, resolutions or proposed amendments to the Constitution and By-Laws have come to the Secretary for transmission to the House of Delegates.

In Appreciation

In offering this, his seventeenth consecutive report submitted to the House of Delegates, the Secretary desires to express his grateful appreciation of the helpful consideration and the kindly assistance extended to him by the officers of the Association, by members of the House of Delegates and by the officers and a great many members of component county medical societies and of constituent state medical associations. He also desires to acknowledge his gratitude for the cordial cooperation extended by members of the administrative personnel of the Association and especially his gratitude for the loyal and efficient service of those immediately associated with him in the work of the Secretary's office.

Respectfully submitted. OLIN WEST, Secretary.

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association:

Within the last few years, many problems of the most important interest to medicine have demanded earnest consideration by medical organizations. Most of these problems are not at all new, having been created out of developments that have naturally followed on the continued advancement of scientific medical knowledge and the need for improved methods for applying such knowledge. Some of these problems have been brought up more acutely because of the activities of various agencies outside the medical profession that are most largely concerned with political considerations or because of long-continued economic disturbances. The existing situation is one that has created tremendously larger demands than ever before on the time and effort of the officers, official bodies and administrative personnel of the American Medical Association. It has necessitated expansion in several of the divisional offices and has required some extension in both the nature and the scope of Association activities. The volume of work done in *practically every department during the last year was very* considerably larger than in any preceding year. Present indications are strongly to the effect that even greater demands will be made on the Association in future years and it is reasonable to expect that further expansion of the Association's facilities will be required.

Business Operations

Gross income from all sources for the year ended Dec. 31, 1938, amounted to $1,758,147.09, representing an increase of $2,837.25 over the total income of the preceding year. Total expense for the year ended Dec. 31, 1938, amounted to $1,769,548.60, an increase of $136,481.68 over total expenditures for the year 1937. The net loss for the year was $11,401.51.

Payments received for Fellowship dues and subscriptions in 1938 amounted to $655,875.91 as compared with $670,170.31 in 1937. Total receipts from the sale of advertising space in 1938 amounted to $875,367.43 as compared with $841,042.57 in the preceding year. Income received from interest on investments in 1938 was $86,857.26 and, through the sale of securities, the sum of $2,831.25 was realized.

Collections from subscriptions and Fellowship dues, notwithstanding an increase in both the number of Fellows enrolled and the number of subscribers to THE JOURNAL, were less in 1938 than in the preceding year by the sum of $14,294.40. Receipts from the sale of advertising space were larger than in the preceding year by the sum of $34,324.86. Interest received on investments in 1938 exceeded receipts on this account in 1937 by the sum of $3,293.52. Office salaries and wages in 1938 amounted to $259,953.13, an increase over the preceding year of $11,292.55. The factory payroll in 1938, amounting to $226,389.15, was larger than in 1937 by the sum of $14,867.72. The cost of paper in 1938 was greater than in the preceding year by a sum slightly in excess of $10,000. Expenditures for first class postage in 1938, amounting to $38,871.82, were larger than in 1937 by the sum of $3,341.69, and expenditures for second class postage in 1938 exceeded those of the preceding year by the sum of $2,591.33.

Expenditures incident to the operation of the various councils, bureaus and departments of the Association during the year covered by this report were $458,499.27, representing an increase of $26,496.58 over the expenditures of the preceding year.

Expenditures for legal services, amounting to $67,096.56, were larger in 1938 than in 1937 by the sum of $43,807.96. These larger expenditures were made necessary because of the indictment of the Association at the instance of the federal Department of Justice for alleged violation of the Anti-Trust Laws; a ruling of the Bureau of Internal Revenue under which the Association was made liable for the payment of Social Security taxes and classified as a business league rather than a scientific and educational organization, and several suits filed against the Association.

The building and equipment of the Association have been maintained to the best possible advantage. As this report is

being prepared, some new machinery, including a gathering machine of the latest model, is being installed at a cost of approximately $36,000

The number of employees of the Association is now slightly less than 600, but this number will be considerably increased when the preparation of the next edition of the American Medical Directory is begun

A more detailed presentation of income and expenditures will be found in the reports of the Treasurer and the Auditors, which are submitted as a part of this official report of the Board of Trustees

Summary

Total income in 1938 was larger than in 1937, but the increase in total expenditures was considerably larger than the increase in income. Income from interest on investments was slightly larger in 1938 than in the preceding year. Total expenditures were larger than income by the sum of $11,401.51.

The Journal of the American Medical Association

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION continues to occupy the place achieved in previous years as a leader in the dissemination of knowledge of advances in medical science and as a representative of the point of view of the organized medical profession of the United States

Among the new features developed during the past year has been the Student Section, which appears once each month, the first issue appearing in July 1938 In this section are articles, abridgments of essays and medical news pertaining especially to student activities and to medical schools This section of THE JOURNAL was established by the Board of Trustees in order to inform the practicing physicians of tomorrow concerning the problems of today Much of the material is developed by educators and those interested in the problems of medical education, yet opportunity has been given also to the students, to interns and to residents to discuss problems of special concern to them A questionnaire circulated among students in twenty different medical schools indicated that the majority had a favorable point of view toward the material thus published It is proposed to continue the development of this department to meet the need which is apparent for contact between the student, the intern, the resident and the practicing physician

* This table gives the number of physicians (based on the Fifteenth Edition of the American Medical Directory) in the United States, the number receiving THE JOURNAL and the approximate percentage in each state Copies to physicians in the United States Army, Navy and Public Health Service are not included

The Organization Section of THE JOURNAL has been largely devoted to problems of current interest in the fields of legislation and medical economics Of special interest have been the reports of the results of the surveys of medical service carried out in individual counties and municipalities as well as in some states

Other features currently appearing in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION which have aroused considerable comment are the series of articles on the vitamins, a series of pharmacologic and therapeutic conferences held in the New York Hospital, and the clinical articles developed during the last annual session of the American Medical Association. Thus, while THE JOURNAL has kept abreast of the most important advances in research, it has not neglected the clinical aspects of daily work

The department of Queries and Minor Notes has maintained its popularity. Special issues have appeared during the year devoted to the hospitals, to medical education, to state licensure and to the annual session. Among the research projects conducted by THE JOURNAL have been cooperation with the United States Public Health Service in determining the availability of typing for pneumococci, the annual reports on deaths from typhoid fever and from diphtheria, and a special survey devoted to Fourth of July accidents.

Table 1, included in this report, indicates the number of Fellows and Subscribers on the mailing list of THE JOURNAL in each state on Jan. 1, 1939. There is also shown in this table the number of Fellows and subscribers in other countries, the number of copies of THE JOURNAL sent to advertisers and subscription agents and the number sent as exchanges and complimentary subscriptions. Table 2 indicates the number and the approximate percentage of physicians in each state who receive THE JOURNAL.

The circulation of THE JOURNAL on Jan. 1, 1939, was 99,854, an increase of 2,104 over the preceding year.

Summary

It has been the earnest purpose of the Board of Trustees and of the Editorial Department to maintain The Journal of the American Medical Association in its established position of leadership in the field of medical journalism and to increase its usefulness both as a scientific periodical and as a defender of the public interest.

Among the new features developed during the past year has been the Student Section, which appears once each month, dealing with matters pertaining especially to student activities and to medical schools. It is proposed to continue the development of this department of The Journal so as to meet the apparent need for contact between the student, the intern, the resident and the practicing physician.

The Organization Section of The Journal, devoted to discussions of problems of current interest in the fields of legislation and medical economics, has been well received and will be further developed as opportunity offers.

Special articles dealing with clinical aspects of the daily work of physicians have been published from time to time and apparently have aroused much interest and have been made the subject of much favorable comment.

The popularity of the department of Queries and Minor Notes has been maintained and is apparently serving an important purpose. The publication of special issues devoted to medical education, hospitals, licensure and other phases of the Association's activities have been continued. The Journal has cooperated with various agencies, including agencies of the federal government, and has published annual reports dealing with mortality due to typhoid fever and diphtheria and has undertaken a special survey pertaining to Fourth of July accidents.

Special Journals

The usual high standards, both scientific and mechanical, have been maintained for the special journals during 1938. The number of pages of reading material published was approximately the same as in 1937, except in three of the periodicals, viz. the ARCHIVES OF DERMATOLOGY AND SYPHILOLOGY, the ARCHIVES OF OTOLARYNGOLOGY and the ARCHIVES OF PATHOLOGY. Increases in the number of pages of practically all the periodicals will be necessary if the material that is accepted is to be published within a reasonable length of time. There was an increase in the subscription list of each of the periodicals, ranging from 75 to 225 and totaling 1,168.

During 1938 there was a considerable reduction in the number of pages of advertising carried in these journals, namely 778 as compared with 1,104 in 1937, the result probably of retrenchment on the part of business houses. The loss in receipts from advertising during 1938 as compared with 1937 was $2,240.71.

A special issue of the ARCHIVES OF PATHOLOGY was published in July 1938 as a testimonial to the life and work of Dr. Ludvig Hektoen on the occasion of his seventy-fifth birthday. This issue comprised 448 pages of articles contributed by physicians who were his students or who were closely associated with him in his many activities.

Owing to the unfortunate illness of Dr. Dean DeWitt Lewis, chief editor of the ARCHIVES OF SURGERY, Dr. Waltman Walters was appointed chairman pro tem of the Editorial Board. Drs. Arthur W. Allen of Boston, Alfred Blalock of Nashville, Lester R. Dragstedt of Chicago and Walter E. Dandy of Baltimore have been added to the Editorial Board in order to develop the periodical still further along practical lines.

In addition to the exhaustive articles in experimental surgery published in the past, shorter articles dealing with progress in surgery of clinical application, general reviews of the literature and editorials in which debatable surgical topics can be discussed will be published.

Summary

Slight increases were recorded in the total circulation of all the publications in this group. Only three of the special journals produced income exceeding the costs of publication, namely the Archives of Otolaryngology, the Archives of Ophthalmology and the American Journal of Diseases of Children. Net income for the American Journal of Diseases of Children barely exceeded the cost of publication.

The net loss on the entire group of special journals was $28,883.35, as compared with $25,958.37 in 1937 and $33,821.30 in 1936.

Library

A geographic analysis of requests for service coming to the Library of the American Medical Association indicates that the greatest number of requests come from Illinois, New York, Ohio and Pennsylvania. Nevertheless, every state in the United States and every province in Canada has availed itself of such services. During 1938, 13,012 periodicals were lent to subscribers, an increase of 2,253 loans over 1937.

The Package Library Service continues to supply material to great numbers of inquirers, notwithstanding the fact that similar services have now been set up by several of the individual state medical societies. During 1938, 3,016 packages were distributed to physicians of the United States and of Canada. The subjects on which packages were most frequently requested were alcoholism, arthritis, pneumonia, sulfanilamide, syphilis, tuberculosis and vitamins.

In addition to the lending of periodicals and of packages of references, the Library answered by letter and by telephone approximately 5,000 individual inquiries on medicobibliographic subjects. Moreover, more than 1,500 persons visited the Library during the year in search of material which was supplied to them.

The great demands on the space available in the headquarters office of the Association made necessary during the year the removal of the Employees' Library from the special room which it occupied to a place on the Library floor. The total circulation for the year was 5,100 books. The Employees' Library now owns 2,030 books and subscribes to twenty magazines. Moreover, material is regularly received by loan from the Chicago Public Library.

The QUARTERLY CUMULATIVE INDEX MEDICUS constitutes the major project of the Library department. During 1938 forty additional periodicals were added to the list of periodicals regularly indexed and fifty-six periodicals were selected for occasional indexing of important items. The universal acclaim tendered to this project, which is maintained by the American Medical Association at a considerable loss, indicates not only the necessity of the service but the excellence of its conduct.

Summary

The activities of the Library have been continued along the same lines previously followed. There was a considerable increase in the number of periodicals lent to subscribers, and the Package Library has continued to

supply material largely for the use of members of the Association who do not have ready access to medical libraries. Approximately 5,000 individual inquiries on medicobibliographic subjects were answered during the past year, and more than 1,500 persons visited the Library in search of such material. The Quarterly Cumulative Index Medicus constitutes the major project of the Library department.

Quarterly Cumulative Index Medicus

There was a slight increase in 1938 in the number of subscribers to the QUARTERLY CUMULATIVE INDEX MEDICUS. The cost of production over income was $43,034.71, as compared with $42,616.32 in 1937.

It is undoubtedly true that the general use of the QUARTERLY CUMULATIVE INDEX MEDICUS in libraries has increased, but the number of subscriptions has not grown correspondingly. The INDEX is available for the use of individual physicians and investigators in practically all important medical libraries, in several general libraries and in some hospitals, where a single volume is available for the use of many individuals.

Standard Classified Nomenclature of Disease

The publication of this guide to nomenclature was assumed by the Board of Trustees of the American Medical Association at the request of the National Conference on Nomenclature of Disease, which first issued the volume in 1932. This nomenclature has been approved by most of the leading special scientific organizations in the United States, and most of them have cooperated in its development.

Since the project was taken over by the American Medical Association, nearly 2,000 copies have been sold.

A questionnaire circulated to the hospitals of the United States indicates that 753 hospitals use the Standard Classified Nomenclature.

Steps are being taken toward the preparation of a new revised edition subsequent to the national conference, which will be called in 1940.

Preparation has also been made to undertake the Standard Classified Nomenclature of Surgical Operations.

The New York Hospital has tendered to the American Medical Association the use of its Nomenclature of Operations as a basis for the development of the standard list. A list of consultants is being developed for this purpose and also for revision of Nomenclature of Disease.

Hygeia

The maintenance of the circulation of HYGEIA, the recognition of its worth particularly by educators throughout the United States, and the innumerable citations from its pages appearing regularly in digest publications, in other health periodicals, in bulletins of various industrial and similar organizations and in newspapers indicate the manner in which HYGEIA has become a source book for information on health throughout the nation. Moreover, several radio programs are now devoted largely each week to citation of material taken from this publication. Beginning with the current volume, improvements were made in the typography, arrangement and illustration of the magazine. A prompt response ensued on the part of numerous readers. Every effort is being made by the Board of Trustees to further the development of this publication as an invaluable contact directly with the public and as a means of extending more widely the benefits of medical science.

The circulation of HYGEIA has been maintained above the 100,000 mark. Through the splendid efforts of the Woman's Auxiliary in Tennessee, an order was received from the state of Tennessee for 6,182 subscriptions whereby the magazine was placed in the public schools throughout Tennessee. Income from the sale of advertising space in HYGEIA has rather steadily declined.

The loss incurred on account of the publication of HYGEIA in 1938 was $18,896.12, as compared with a loss of $31,004.90 in 1937. The indicated reduction was accomplished by resorting to all possible economies that would not interfere with improvement in the magazine.

Summary

Improvements have been made in the typography, arrangement and illustration of Hygeia. The magazine apparently has established itself in many schools as a source book for information on health, and material from its columns is being reproduced in a large number of lay publications and has been used to some extent in radio programs.

The circulation of Hygeia has been maintained above 100,000. The net loss on this publication for the year 1938 was $18,896.12, as compared with a loss of $31,004.90 in 1937.

Book Publications of the American Medical Association

While the American Medical Association does not contemplate any large invasion of the field of book publication, the assembling of material first issued in the form of feature articles is a logical step in its work. The volumes now available include "The Handbook of Therapy," in its eleventh edition, "The Technic of Medication," in its third edition, "Medical Writing: Its Art and Technic," "A. M. A. Intern's Manual," "The Primer on Fractures," now in its fourth edition, "The Handbook of Physical Therapy," in its third edition, "Medicolegal Cases" and "Simple Lessons in Human Anatomy." In the course of preparation are a new volume on the vitamins and a series of twenty-four cases entitled "The Pharmacopeia and the Physician," prepared in cooperation with the United States Pharmacopeial Committee. The Association publishes, moreover, the special volumes issued by the Council on Pharmacy and Chemistry and the Bureau of Investigation. In process of preparation is a new book to be called "Accepted Foods," which is being prepared under the auspices of the Council on Foods.

American Medical Directory

The American Medical Directory is in some respects one of the most important of the Association's publications. The information contained in this volume is essential for the purposes of the Association itself and is of great value to constituent state and territorial medical associations, to component county medical societies and to many agencies, governmental and otherwise, that find it necessary to have dependable information concerning the medical profession and medical institutions.

The Fifteenth Edition of the American Medical Directory was published in 1938. The names and addresses of the legally qualified physicians of the United States and Canada, together with biographic material concerning them, are published in the Directory. The number of names listed in 1938 was 188,916, as compared with 183,312 in the Fourteenth Edition. While 13,811 new names were printed in the Fifteenth Edition of the Directory, 8,008 physicians whose names appeared in the Fourteenth Edition died in the interim, and approximately 200 names which appeared in the Fourteenth Edition did not appear in the Fifteenth Edition for various reasons, including revocation of licenses and withdrawals from practice for other reasons.

The publication costs of the Fifteenth Edition of the American Medical Directory amounted to $165,794.47. The sales of the Directory up to the time of the preparation of this report have failed to equal production costs by the sum of $8,488.90. It is reasonable to expect that this deficit will be reduced to some extent by additional sales.

Summary

The Fifteenth Edition of the American Medical Directory contains the names of 188,916 physicians of the United States and Canada. More than 13,000 new names appeared in this edition, while approximately 8,000 names *which appeared in the Fourteenth Edition were dropped*

because of deaths and for other valid reasons. The cost of compiling and publishing the information presented in the Fifteenth Edition of the Directory was $165,794.47. The income received from sales up to the time of preparation of this report was less than the cost of publication by the sum of $8,488.90.

Cooperative Medical Advertising Bureau

The Cooperative Medical Advertising Bureau is operated for the benefit of official publications of constituent state medical associations, and thirty-three of these publications are represented in the Bureau. Advertising contracts secured through this Bureau for state journals in 1938 amounted to $166,704.57, which represents an increase of about $10,000 over the year 1937. Commissions earned by the Bureau amounted to $33,392.45, of which amount the sum of $17,500 was rebated to the state journals after the costs of maintaining the Bureau were subtracted from the total amount of commissions earned.

Thirty-three state medical journals were members of the Cooperative Medical Advertising Bureau in 1938. In January 1939 the *New York State Journal of Medicine* was added to the list of publications served by this Bureau.

Summary

The earnings of the Cooperative Medical Advertising Bureau in 1938 were $33,392.45, of which amount the sum of $17,500 was distributed among the state journals after the operating costs of the Bureau had been deducted. The total amount of the value of advertising contracts secured through the Bureau for the state medical journals was $166,704.57.

The New York State Journal of Medicine was added on Jan. 1, 1939, to the list of journals participating in the Bureau.

Mailing and Order Department

A total of 69,736 orders were handled by the Order Department during the year covered by this report. The total units distributed were 398,564. The use of more than 5,000 mail bags with a total weight of 156 tons was required to carry the material distributed through orders received.

The total number of pieces of first and third class mail sent out by the Mailing Department was 1,699,477. Nearly three and one-half million envelops were required for all mailing purposes.

American Medical Association News

During 1938-1939 a department to aid in press relations was established in the headquarters office, in charge of a professional newspaper writer, Mr. Lawrence C. Salter. From this department each week there is issued the AMERICAN MEDICAL ASSOCIATION NEWS, containing excerpts or rewrites of material published in the various publications of the American Medical Association and also special announcements concerning the activities of the organization. This bulletin is sent regularly to all press associations, to news sources, to periodicals and to the editors of medical journals and of bulletins of county medical societies.

Conference with Representatives of Hospital Associations

On invitation of the Board of Trustees of the American Medical Association, members of the board of trustees of the American Hospital Association and representatives of the Catholic Hospital Association and the American Protestant Hospital Association met in conference at the offices of the American Medical Association on Feb. 15, 1939. Various matters of mutual interest to the groups represented were frankly discussed, and it was most gratifying to note that there was decided unanimity of opinion with respect to many phases of the general subject of medical care in hospitals, even though there may be some differences between the basic policies of one or more hospital associations and those of the American Medical Association.

Among questions that received consideration at this conference were those having to do with group hospitalization and an apparent tendency on the part of some of the hospital groups to include both special and general medical service in contracts offered to their members as well as other questions of major importance and present interest. During the conference the following resolution was unanimously adopted by the representatives of the three hospital associations:

> The representatives of the American Hospital Association, the Catholic Hospital Association and the American Protestant Hospital Association here present desire to express to the Board of Trustees of the American Medical Association their confidence in the leadership of the medical profession in furthering the excellence of medical service and in aiding the solution of problems of the distribution and provision of medical care.

At a later time the following resolution was approved by all those who participated in the conference:

> It is moved that the following be the sense of this meeting:
> This gathering of the Trustees of the American Medical Association with representatives of the American Hospital Association, the Catholic Hospital Association and the American Protestant Hospital Association express their gratification on the unanimity of opinion developed concerning many phases of the health problems of the nation achieved by mutual discussion. It is recommended to the American Medical Association, the American Hospital Association, the Catholic Hospital Association and the American Protestant Hospital Association that such joint meetings of their representatives be held for the consideration of problems of mutual concern.

It is the considered opinion of the members of the Board of Trustees that this conference with the representatives of the hospital associations served a most useful purpose in that it provided opportunity for open discussion of important problems and established an understanding which possibly could not have been brought about otherwise.

It was not possible that all matters of mutual interest to those who participated in the conference could be fully considered, nor did it seem wise to undertake at the time to examine minutely the reasons for some possible differences in the policies of all the organizations represented in the conference. There seemed to be unanimous agreement that the physician is supreme in the hospital in all matters pertaining to medical service rendered in hospitals.

As indicated by the terms of the resolution which received the unanimous approval of all present, it is hoped that similar conferences may be held from time to time in the future with the official approval of the American Hospital Association, the Catholic Hospital Association, the American Protestant Hospital Association and the American Medical Association.

The Board of Trustees offers the recommendation to the House of Delegates that such approval be indicated at this session.

Official Contact with Other National Organizations

Various important medical organizations of national scope not officially affiliated with the American Medical Association have within recent years concerned themselves with the consideration of many matters which they had not previously officially considered. It seems to be highly desirable that, so far as possible, concerted effort on the part of all groups interested in the promotion of the art and science of medicine, in the extension of medical service for the benefit of all classes, in improving the methods for applying scientific medical knowledge and in the maintenance of worthy professional ideals should be fully established at the earliest possible time.

For that reason the Board of Trustees has decided to invite the proper official representatives of certain medical organizations of national scope to participate in conferences similar to that recently attended by the members of official bodies of the three national hospital associations. The first invitation was recently extended to the Board of Regents of the American College of Physicians.

Communications from National Medical Association, Inc.

Official representatives of the National Medical Association, Inc., which is the national organization of Negro physicians in the United States, appeared before the Board of Trustees and later before the House of Delegates of the Association at the special session of the House held in Chicago in September 1938.

The National Medical Association, Inc., includes in its membership Negro physicians, dentists and pharmacists. According to the statement of its president, Dr. George W. Bowles, the association has approximately 4,000 members, this number having been determined from the records of the organization in the hands of its secretary. From the same source an estimate is offered to the effect that there are approximately 5,300 Negro physicians in the United States.

The representatives of the National Medical Association addressed the House of Delegates at the special session in September and expressed a desire on the part of the officers of that association to cooperate to the fullest possible extent in maintaining the policies of the American Medical Association as established by its House of Delegates. They asked for such aid as might be extended to them by the American Medical Association in securing recognition of Negro physicians, members of the National Medical Association, by certain agencies of the federal government and of state governments. They also expressed the desire to have the designation "col.," which appears with the names of Negro physicians listed in the American Medical Directory, removed.

The Board of Trustees has given careful and sympathetic consideration to the communications received from the elected officers and other representatives of the National Medical Association, Inc., and will undertake to work out some method for listing Negro physicians in the American Medical Directory in a manner that will not be objectionable to them.

The Board of Trustees desires to submit to the House of Delegates the communications referred to with the recommendation that they be referred to a reference committee for consideration of the points involved.

The president of the National Medical Association, Inc., has been informed that this action would be taken by the Board of Trustees and that the Board believes that the reference committee of the House of Delegates to which these matters may be referred will be glad to have official representatives of the National Medical Association appear before it.

Division of Drugs, Foods and Physical Therapy

The creation of the Division of Drugs, Foods and Physical Therapy has proved to be an effective means of coordinating the work of the Council on Pharmacy and Chemistry, the Council on Foods, the Council on Physical Therapy and the Chemical Laboratory. This Division has also been concerned with the activities of the Advisory Committee on Advertising of Cosmetics and Soaps, the Councils' Committee on Contraceptives and the Committee on Medical Patents.

Council on Pharmacy and Chemistry

The year 1938 will be memorable because of the passage by the Congress of (*a*) the Wheeler-Lea Bill regulating the advertisements of foods, drugs and cosmetic preparations outside the package, including advertising over the radio, through newspapers and even by the spoken word; (*b*) the Food, Drug and Cosmetic Act, which places in the hands of the Department of Agriculture much more effective weapons to control the supervision of labeling and advertising accompanying the packages of products sold to the public, and also requires disclosure of the contents of preparations; (*c*) the licensing drug bill providing that no new drug preparation may be placed in interstate commerce after June 25, 1938, until it has received a license from the Food and Drug Administration, which is charged with the duty of determining whether or not the product may be harmful under the conditions recommended. These laws are designed to carry out, to a certain extent, policies similar to those long since established by the Council on Pharmacy and Chemistry and by the Bureau of Investigation. While they do not yet contain some of the provisions which seem to be in order, such as quantitative disclosure of formula, these statutes do clearly recognize the validity of principles maintained by various departments of the American Medical Association unceasingly since 1905, the year in which the Council on Pharmacy and Chemistry was created.

The Food, Drug and Cosmetic Act represents an endeavor to minimize counter prescribing. Physicians should therefore welcome this opportunity to encourage the proper prescribing of drugs and do all in their power to cooperate with pharmacists against the counter exploitation of drugs used in the scientific practice of medicine. The work of the Council on Pharmacy and Chemistry will be aided in certain directions by force of these new laws, but it will not be lessened. Council recognition of products is coming to mean more and more to physicians and to manufacturers, as is shown by the fact that the work of the Council increases each year. When a drug passes scrutiny of the Council it has shown promise of merit and, if it is accepted, the manufacturer must agree to market it according to claims the Council believes to be justified. The products of certain manufacturers are not recognized by the Council. Few agencies are in position to exercise such discrimination as is shown by the Council in the acceptance of pharmaceutic products. The law now recognizes and provides for the pronouncements of expert medical opinion and it is expected that the opinions of the Council on Pharmacy and Chemistry will have decided influence in helping to formulate decisions on the current use of therapeutic agents. A number of concerns whose products are not recognized by the Council have recently made active progress in revising their catalogues to avoid unfavorable official rulings. It is quite likely that some of these producers will be able to show sufficient revision to warrant the Council's considering certain of their drugs for inclusion in New and Nonofficial Remedies.

On Sept. 1, 1938, announcement was made of the acceptance of products of the Upjohn Company and that company is now cooperating well with the Council. The Council now has catalogues of approximately a dozen manufacturers before it with a view to determining the status of the products of these concerns.

The Council wishes to take this opportunity to express to the members of the American Medical Association its appreciation of the increasing support and recognition which is being given to its work.

INCREASE IN MEMBERSHIP OF THE COUNCIL

Because of the widening field in drug therapeusis it has been necessary to increase the membership of the Council by two members.

PUBLICATIONS OF THE COUNCIL

New and Nonofficial Remedies.—A usual edition of this publication was issued in 1938. Two supplements were issued as usual, one on August 1 and one on November 1. It is to be emphasized that New and Nonofficial Remedies is a current publication, issued annually, the contents of which are being constantly changed to keep in step with the rapid advancement of therapy. The number of copies sold in 1938 was 5,242. In addition 6,300 paperbound copies were distributed to one class of each class A medical school.

The Epitome of the U. S. Pharmacopeia and National Formulary.—It was not necessary to revise this book, since few changes were made in the Interim Supplement issued by the Revision Committee of the U. S. Pharmacopeia or by the Revision Committee of the National Furmulary. The demand for the Epitome was very good, the number of copies sold in 1938 having been 7,809.

Useful Drugs.—Useful Drugs has found increasingly wide acceptance among the profession and particularly in the medical schools. In 1938 a new edition was issued. Of late it has been necessary to revise the book approximately every two years. The motto for this book might well be a modification of the old aphorism "It is better to know a few drugs well than many drugs poorly." The number of copies of Useful Drugs sold in 1938 was 7,397.

Glandular Physiology and Therapy.—This book was issued at the close of 1935, after which there was one reprinting. The book is in need of revision and it is anticipated that the new edition will be published during 1940. The number of copies of Glandular Physiology and Therapy sold in 1938 was 710.

A. M. A. Interns' Manual.—This represents a radical revision of a publication previously known as Hospital Practice for Interns. It was issued for the first time in the late spring of

1938. The reception given to the book was greater than was anticipated. In it are contained the official statements from the Council on Medical Education and Hospitals on the relationship of the intern to the hospital, a brief discussion of physical therapy prepared by the Council on Physical Therapy, and a statement on foods and nutrition prepared by the Council on Foods. In addition, there is considerable material on various types of drugs—dosages and indications—which come within the purview of the Council on Pharmacy and Chemistry. This represents truly a cooperative effort of the various councils of the Association in a common field. The number of copies sold in approximately a half year was 1,943.

REPORTS OF THE COUNCIL

The Council issued the usual number of reports. Undoubtedly more interest has been shown in sulfanilamide than in any other drug introduced in medicine during the last few years, and the Council has again revised its description. During the year the Council coined a nonproprietary name for a derivative of sulfanilamide which had been introduced in the United States under undesirable proprietary names. Sulfapyridine, the name coined by the Council, has received wide acceptance. A number of articles which represent extensive work were published by the Council, such as those on the Present Status of Ergonovine, the "new" alkaloid from ergot; Creosote and Guaiacol Compounds, all of which were omitted from New and Nonofficial Remedies; the Present Status of Immune Globulin (Human); the Present Status of Picrotoxin in Poisoning by the Barbiturates, and a number of reports on other substances. Space does not permit detailed statement of the many products and substances which have been passed on by the Council.

COOPERATIVE COMMITTEE ON VITAMINS

The Council on Pharmacy and Chemistry and the Council on Foods have a joint committee on vitamins. Because of the importance of the vitamin problems which were before the councils during 1938 a special meeting of this committee, together with the members of the two councils who are not members of the committee, was called early in December. In order to aid in appreciation of the scope of the discussions, mention is made of the following among the topics presented for action: permissible claims for vitamin A, riboflavin, thiamin chloride, nicotinic acid, cevitamic (ascorbic) acid, vitamin D, vitamins A and D together, viosterol preparations, and vitamin E. The Cooperative Committee of the Councils endorsed the action of the American Society of Biological Chemists and the American Society of Nutrition that the term "vitamin F" be not recognized. It also considered the possibility of reducing the number of types of vitamin A and D preparations by prescribing limits of potency and dosages for different classes of vitamin products. The new problems of nomenclature in relation to vitamins were thoroughly discussed, as were international standards. Other topics dealt with the work of the Council on Foods, such as fortification of various foods with vitamins, and statement of general policy toward such preparations.

Based on these discussions there is to be published in 1939 a review of the action of this committee. Scientifically the conception of vitamins is becoming much clearer and each year brings contributions to the knowledge of the subject. On the other hand, the vitamins have been played up in a grossly unscientific manner to the public. Particularly to be disparaged are the many unnecessary polypharmaceutic preparations containing vitamins, sometimes combined with minerals, which are constantly urged on the public. There is but little need for vitamins as contained in such products and certainly no need medically of complex unscientific mixtures sold under "catchy" names, with misleading claims indicating usefulness in the treatment of various diseases and as cosmetics.

The Council on Pharmacy and Chemistry, in cooperation with the Council on Foods, expects to issue in 1939 a book on vitamins containing the articles published under the joint auspices of these councils. These articles have been thoroughly revised and are being edited by the Secretary of the Council on Foods.

During the year, nicotinic acid was standardized and a number of brands were submitted to the Council on Pharmacy and Chemistry. The Council also has under consideration the newer addition to the vitamins now called vitamin K. It is encouraging to note that scientific terms are gradually replacing the use of such unsatisfactory designations as are indicated by alphabetic designations. Practically all the known pure crystalline substances are now included in New and Nonofficial Remedies under chemical names.

PROBLEMS OF NOMENCLATURE

The foregoing discussion indicates in a small measure the various problems before the Council. Appreciation of the work of any group having so many questions before it requires a large background of experience. It is therefore sometimes difficult to understand adequately why the Council has been compelled to take this or that action. Practically, most of the complaints that are received in the Council office deal with matters of nomenclature. It is difficult for some persons to see the necessity of not establishing precedents by the use of names which are therapeutically suggestive and that, should therapeutically suggestive names be once recognized, the chaotic condition of nomenclature which was prevalent in 1905 would again be in the course of establishment. The Council is also insistent that there shall be only one proprietary name to any substance and such a proprietary name is granted either because of discovery of a novel preparation or discovery of novel medicinal properties, either of which constitutes a definition for distinct originality.

MEMBERSHIP OF THE COUNCIL

The Council lost by resignation one of its valued members, Dr. E. M. Bailey, who was forced to retire because of illness. Dr. Bailey had been a member of the Council on Pharmacy and Chemistry and of the Council on Foods since 1930. He was chairman of the Committee on Rules and Procedure of the Council on Pharmacy and Chemistry and served admirably as chairman of the Cooperative Committee on Policy, Rules and Procedure, representing the three councils. The members of the Council have recorded their appreciation of the excellent services which Dr. Bailey gave to the medical profession during these years though he himself was not a member of that profesion. It is one of the glories of science in general that men of distinction who are not physicians are willing to serve the medical profession unselfishly in its endeavor to promote the best interests of the public and of medicine.

Summary

Important legislation enacted by Congress during the year 1938 included a bill regulating the advertising of foods, drugs and cosmetic preparations outside the package, over the radio and through newspapers, the food, drug and cosmetic act providing for more effective control over the supervision of labeling and advertising accompanying packaged products and requiring the disclosure of the contents of the preparations, and an act providing that no new drug preparation could be placed in interstate commerce after June 25, 1938, until it had received a license from the Food and Drug Administration. These laws are designed to carry out to a certain extent policies similar to those of the Council on Pharmacy and Chemistry and will in some respects offer support to the work of this Council. The law now recognizes and provides for pronouncements of expert medical opinion, and it is possible that the official opinions of the Council on Pharmacy and Chemistry may have some important influence in aiding in the formulation of decisions on the use of therapeutic agents.

Some manufacturers whose products are not recognized by the Council have made revisions in their catalogues for the purpose of bringing them into compliance with newly enacted legislation, and some of these manufacturers may be able to show sufficient revision to warrant consideration by the Council of some of their products for inclusion in New and Nonofficial Remedies.

Increase in the volume of work necessarily undertaken by the Council required the addition of two members.

Publications of the Council have enjoyed fairly satisfactory distribution, and it has become necessary to issue new editions of some of them and to prepare for early revision of others. The issuance of reports

designed to provide the medical profession with information concerning the status of new drugs has been continued.

The Cooperative Committee on Vitamins, a joint committee representing the Council on Pharmacy and Chemistry and the Council on Foods, has been created for the purpose of conducting intensive studies pertaining to vitamins. Under the auspices of this committee, important articles pertaining to vitamins have been prepared and, after publication in The Journal, will be brought together for publication in book form.

Council on Foods

It is one of the functions of the Council on Foods to evaluate evidence regarding the nutritional significance of foods and, by means of its seal, to designate as acceptable the claims contained in the advertising of wholesome food products. In this work the Council has continued to receive the cooperation of many producers. Although there has been a limitation in the classes of foods which are accepted, during 1938 approximately 400 products were given consideration. For most of these it was necessary to recommend changes in labeling or advertising or both. Only six products were rejected during the year because firms were unwilling to meet requirements. Thus, it would seem that the work of the Council is bearing fruit, although it would be difficult to obtain an accurate measure of it.

Despite restrictions in the scope of the Council's activities, the labors of its members have greatly increased. The evaluation of scientific evidence and the examination of advertising demand considerable time. During a single month the Council receives approximately 4,000 typewritten pages of radio "continuity" alone. No proper estimate can be made of the amount of advertising for newspapers and periodicals and longer statements such as are contained in booklets and pamphlets that has been given careful consideration. Perhaps the increased powers of governmental agencies provided by the new Food, Drug and Cosmetic Act and the Wheeler-Lea Bill may in time relieve the Council of much of this work and thus permit more time to be spent on the evaluation of scientific and medical data on the value of foods in preserving health.

PUBLICATIONS OF THE COUNCIL

During the year there was prepared for the A. M. A. Interns' Manual a section on Diet and Nutrition. There also was published a pamphlet containing a brief account of some of the principles which underlie the selection of foods for an adequate diet. This pamphlet, entitled "The 'Normal' Diet," was distributed in connection with the exhibit of the Council at the San Francisco meeting. Copies were made available for distribution in reply to the great number of inquiries received by the Council office for information about foods and diet from physicians, students and the general public.

When canned orange juice and other canned fruit juices are substituted for the fresh orange juice which commonly is used in the feeding of infants, there is interest in the vitamin C content of the products. Vitamin C is readily destroyed by oxidation, particularly on heating. Modern canning procedures are designed so as to conserve the vitamin. In order to obtain further information on this point, Dr. E. M. Bailey of the Connecticut Agricultural Experiment Station, New Haven, has supplied for the Council comparative data on the vitamin C content of accepted fruit juices (orange, lemon, grapefruit, pineapple and tomato) determined by the chemical titration method. The Council, in its report, concluded that all of the products examined may be considered excellent sources of vitamin C.

In collaboration with the Council on Pharmacy and Chemistry, arrangements were made for the preparation of a series of articles on the vitamins. These were published during 1938 in THE JOURNAL. There were thirty-one articles altogether, which reviewed the chemistry, physiology and dietetic and therapeutic values of each of the vitamins. Judging by inquiries, these authoritative reviews, prepared by leading investigators in the field, have proved to be most useful. Arrangements now have been made for publication of the series in book form.

Progress also has been made in the compilation of material for the book "Accepted Foods."

RULES AND DECISIONS

As information has accumulated regarding foods and their nutritional value, it has been necessary for the Council to revise the requirements for accepted products. Some of the items which have been given careful study are indicated by the changes made in the Rules and Decisions.

The Council has always believed that the ingredients of processed foods should be made known, and particularly of the products intended for special dietetic uses and for feeding infants. Prominent declaration should be made of the ingredients and of the amounts of the essential dietary substances on labels. In accordance with these fundamental policies, the Rules Governing Package Labels and Advertising of special purpose foods have been revised by the incorporation of the following statements:

> The labels and advertising shall contain a statement listing all dietary ingredients of nutritional significance in the order of decreasing predominance by weight and shall indicate the special purpose for which the product is intended. These statements, so far as is practical, should be in close proximity to the trade name. In addition, as much of the following information should be given as is significant to permit the intelligent use of the particular product by the consumer: specific properties, vitamin and mineral content, the calories per gram or ounce, and the grams each of carbohydrate, protein and fat per portion.

Claims for the vitamin content of food products intended for therapeutic purposes should be supported by suitable evidence. As a guide to producers and as an expression of Council policy, the following statement concerning the kind of evidence desired together with a general suggestion about how this evidence may be obtained has been incorporated under the Rules Governing Package Labels and Advertising:

> In the case of special purpose foods designed to supplement the vitamin content of therapeutic and other diets, satisfactory evidence must be presented that storage under ordinary conditions does not lower the vitamin potency of the product below the assay values claimed. Suitable evidence on this point, for products which ordinarily are kept at room temperature, would be obtained by assay of specimens maintained for three months at a temperature of 100 degrees Fahrenheit. For products which ordinarily are kept in the refrigerator, suitable evidence would be obtained by assay of specimens which have been maintained for suitable periods of time at refrigerator temperature.

The section of the Rules headed "Vitamins" under "Form of Submission of Foods for Consideration" likewise has been amended to read:

> Specific vitamin claims must be based on satisfactory evidence, preferably by direct biologic tests of marked samples by a competent investigator. Report of assays should be complete enough to enable appraisal of the work and the deductions therefrom. In the case of vitamin C, chemical titration may be sufficient evidence of the ascorbic acid potency of products for which it has been demonstrated that the chemical method is sufficiently precise. It is important that assay of the vitamin potency of food products be performed on samples which have been kept under conditions of storage comparable to those to which the food product is likely to be subjected.

It was formerly customary to add a small amount of bread crumbs or other cereal food to strained vegetables prepared for use in infant feeding in order to thicken them slightly and to increase their caloric value. The use of cereal in the preparation of strained vegetables for infant feeding has now been largely abandoned, but vegetable soups prepared for infants and young children frequently contain cereal or potato as thickening agents and for the added food value which they supply. Commercially prepared strained vegetable soups with few exceptions contain cereal ingredients in amounts ranging from 1.7 to 12 per cent by weight. The cereals used are chiefly barley, rice and wheat germ. One cereal product only or a mixture of any two or all three of the cereals named may be employed. The nutritional value of the added cereal for healthy babies is recognized.

Because of the small amount of cereal which may be used and the fineness of division of strained foods, the presence of cereal may not be immediately apparent on inspection of the product. The Council believes that the container label of foods should conspicuously present such information as will inform the public of the ingredients of the food within the package. In the case of strained vegetable soups the Council further believes that prominent declaration of the presence of cereal in the product may be of importance to physicians pre-

scribing these foods and the following decision on this point has been adopted:

Added cereal in sieved vegetable soups intended for infant feeding or for special diets shall be given appropriate and prominent declaration on the main panel face of the package label.

The following decision concerning the use of the word "cream" on the labels and in advertising of evaporated milk is self explanatory:

There have appeared on labels and in advertising for various brands of evaporated milk certain statements which the Council believes are undesirable, such as "use evaporated milk instead of cream," "for all your cream needs" and "use as cream." Although evaporated milk is often useful as a culinary aid in situations in which cream is commonly used, the composition of evaporated milk differs from that of cream; statements that imply that evaporated milk is practically the same as cream are nutritionally incorrect and misleading. The claim that evaporated milk has the "consistency of cream" may be correct from a physical point of view; however, the Council regards the expression as objectionable because of the suggestion of similar nutritive properties. The use of evaporated milk in tea, coffee and for other purposes can be suggested without recourse to the word "cream."

GENERAL POLICIES

The funds supporting the work of the Council on Foods come entirely from the American Medical Association. There is no charge of any kind for the seal of acceptance and there never has been.

In order to conserve its facilities, the Council has found it necessary to omit certain foods from its scope. Among the exempted products are well known perishable foods such as fresh fruits and vegetables, fresh meat and eggs and ordinary pasteurized milk. As long ago as 1936 it was found necessary to include individual brands of butter in the exempted list. During 1938 it was brought to the attention of the Council that exemption of butter with continued consideration of oleomargine created a difficulty because of the belief of many that the seal of acceptance constitutes a recommendation. The Council has stated repeatedly that the seal means only that in its opinion the product on which it appears is a wholesome food and that the labeling and advertising comply with Council requirements. It also may be emphasized that the Council gives consideration to so-called educational advertising of trade associations or firms for classes of foods and, on material which is acceptable, permits the display of the seal, usually with an added statement to the effect that the seal denotes that the nutritional claims are acceptable to the Council. With regard to butter, however, the disadvantages of not being able to obtain the seal were felt so keenly by members of the dairy industry that the House of Delegates requested the Council to reestablish suitable standards for the acceptance of butter and the advertising associated therewith. The Council has been spending considerable time in an endeavor to take care of the added work that would be involved and it is expected that some general method of procedure shortly will be devised.

MEMBERSHIP AND CONSULTANTS

During the year the term of membership of Dr. Lydia J. Roberts expired and she was reelected by the Board of Trustees to serve another period of five years. Dr. George R. Cowgill was elected to serve the unexpired term of Dr. Edwin O. Jordan (deceased), and Dr. Irvine McQuarrie was elected to take the place of Dr. Grover Powers, who resigned because of the pressure of other duties. The staff of the Council office remains the same except for the appointment of Dr. Harriet Morgan Fyler to replace Dr. Marjorie Pickens, who resigned to become research associate in the Department of Home Economics, University of Illinois.

The services of the following persons, who were called on as consultants during the year, are gratefully acknowledged: Dr. Walter C. Alvarez, Dr. Hugh R. Butt, Dr. A. J. Carlson, Dr. Henry C. Eckstein, Dr. George B. Eusterman, Miss Mary A. Foley, Dr. Ramon F. Hanzal, Dr. A. C. Ivy, Dr. William E. Krauss, Dr. Grace MacLeod, Dr. E. M. Nelson, Dr. Grover F. Powers, Dr. Henry C. Sherman, Dr. Albert M. Snell and Dr. Genevieve Stearns.

Summary

A review of activities of the Council during 1938 emphasizes again the continued cooperation of members of the food industry. Few products have been accepted without requiring changes in nutritional claims on labels or in advertising and very few products have been rejected because producers were unwilling or unable to meet the requirements. The newer legislation on foods may enable the Council to concentrate more on the evaluation of scientific and medical opinion on the value of foods in preserving health. Reports of this nature have been published. In a study of the comparative value of the vitamin C potency of canned fruit juices it was found that accepted products compare favorably with fresh juices and rate as excellent sources of the antiscorbutic factor. The Council has prepared brief accounts of the principles which underlie the selection of an adequate diet, one such report having been published in the A. M. A. Interns' Manual. In cooperation with the Council on Pharmacy and Chemistry there was published in The Journal a series of noteworthy articles on the vitamins prepared by prominent investigators in the field. These articles now are being collected for publication in book form. There are recorded several revisions in the Rules and Decisions of the Council which were made with the view of having the requirements for accepted products more definite in the light of newer knowledge. The request of the House of Delegates for the reestablishment of suitable standards for the acceptance of butter, and the advertising associated therewith, has resulted in a concentrated effort on the part of the Council to devise some general method of procedure whereby meritorious foods which now are exempted from consideration, because of limitations in facilities, may be given proper recognition.

Council on Physical Therapy

Among important activities of the Council on Physical Therapy within the last year were those concerned with the consideration of radium and radon seeds, roentgen ray apparatus, artificial limbs, hearing aids and the formulation of standards for audiometers, advice in problems of research, a study of radio interference caused by electromedical equipment, revision of the Handbook of Physical Therapy and the booklet "Apparatus Accepted," and the investigation of apparatus. The gathering and dissemination of information that will aid the medical profession in determining the therapeutic value of certain devices and methods employed in the administration of physical therapy constitutes one of the purposes for which this Council was created. Through official reports and scientific articles published in THE JOURNAL, conferences with interested groups and a voluminous correspondence, the Council is attempting to accomplish this purpose.

RADIUM AND RADON

After a thorough study of the question of leakage and filtration of radon seeds, the Council is now in a position to go forward with the consideration of these products, using as a guide the report "Radon Seeds," to be published in THE JOURNAL. The preliminary work consisted of testing seeds purchased on the open market in a prominent laboratory manned by qualified physicists aided by qualified physicians.

In view of the action taken by the House of Delegates at the San Francisco session of the American Medical Association in June 1938 disapproving the rental of radium under certain conditions, the Council is now in a position to proceed with the consideration of the radium products which have come to its attention.

ROENTGEN RAY APPARATUS

The Council is continuing investigations of roentgen ray apparatus with a view to accepting for inclusion in its official lists such apparatus as meets requirements of the Council for that purpose. While it is easily possible to secure satisfactory tests of the smaller equipment of this nature, it is much more difficult to secure the necessary facilities for testing the largest and most powerful roentgen ray machines.

ARTIFICIAL LIMBS

At the suggestion of manufacturers of artificial limbs, a joint meeting of representatives of the Council on Physical Therapy

and of the Association of Limb Manufacturers of America was held in Chicago, at which time the question of sites for amputation, fitting of artificial limbs, standards for acceptance and sales methods were discussed. Articles are now in preparation dealing with these subjects and they will be published in THE JOURNAL.

AUDIOMETERS AND HEARING AIDS

A meeting was held in Chicago at which representatives of the hearing aid industry and consultants for the Council were present. As a result of action taken at this meeting, the "Minimum Requirements for Acceptable Audiometers" were revised and published. Problems discussed at this meeting were (1) the establishment of the energy value for the threshold of hearing, (2) the practicability of fitting hearing aids by means of audiometers and (3) requirements for acceptance of hearing aids. A better understanding of the mutual problems of the otologist and the manufacturers of audiometers and hearing aids was reached.

INTERFERENCE WITH RADIO COMMUNICATION

By mutual agreement the Federal Communications Commission and the Council on Physical Therapy held a joint informal meeting in the Harkness Theatre, Columbia University, New York, in January 1939, at which the problem of interference with radio communication caused by electromedical equipment was given consideration. Attending the meeting were members of the medical profession, representatives of manufacturers of electromedical equipment and of radio manufacturers, officials of the Federal Communications Commission, and other interested groups. At this meeting specialists and engineers in the radio communication field demonstrated interference by short wave diathermy with aural reception and television. The important accomplishment of the meeting was better appreciation of the mutual problems confronting the medical profession and the communication interests. Two solutions were proposed: (1) screening of the treatment room and (2) the allocation of certain radio bands or channels. No definite action was taken, however, since it was believed that further consideration of this problem was necessary.

HANDBOOK OF PHYSICAL THERAPY

The third edition of the Handbook of Physical Therapy has been revised and brought up to date. New articles prepared and included in the volume are on the following subjects: fever therapy, medical diathermy, neutron rays, ultraviolet and infrared radiation, electrolysis, physical therapy in fractures and infantile paralysis, psychoses and neurologic conditions and equipment for physical therapy departments in hospitals. Revisions have also been made in most of the articles retained from the second edition.

INVESTIGATION OF APPARATUS

As usual, much of the Council's time has been concerned with the consideration of apparatus. Of the 100 pieces of apparatus considered, forty were accepted, eleven were rejected, and the remainder were withdrawn from the market or recommendation made that the units be improved and resubmitted to the Council for consideration. A new edition of the booklet "Apparatus Accepted" was published in September, 1938, bringing up to date the information on apparatus that has been reported on by the Council.

GRANTS-IN-AID OF RESEARCH

Several applications were presented to the Council requesting aid in research. Only one application was approved. The Council believes there are many problems in the field of physical therapy deserving careful investigation and will carefully review all requests for grants in aid of research.

EDUCATION

In its educational program, designed to promote sound physical therapy, the Council has had the able assistance of a group of consultants whose efforts have been untiring in this field. Approximately seventy lectures were given and instruction in physical therapy was instituted in three medical schools. Twenty-six articles and three books were published by this group. The members attended fifteen meetings of physical therapy groups. Efforts to establish an American Board of Physical Therapy culminated in the appointment of a committee to establish such a board which will serve physicians limiting their practice to physical therapy. New departments of physical therapy were established in several hospitals as a result of the Council's efforts.

Five exhibits were shown at various medical meetings, and four new films were prepared on the following subjects: "Aids in Muscle Training," "Underwater Therapy," "Occupational Therapy" and "Massage."

The Council has cooperated with the Council on Medical Education and Hospitals, the American Physiotherapy Association and the American Registry for Physical Therapy Technicians in connection with the consideration of problems concerning educational standards for technicians. It also cooperated with the Section on Ophthalmology of the American Medical Association in the consideration of ophthalmologic devices.

Summary

Briefly, the important work of the Council on Physical Therapy for 1938 has been directed toward the consideration of radium and radon seeds, artificial limbs, audiometers, hearing aids, roentgen ray apparatus, the study of radio interference caused by electromedical equipment, the revision of the Handbook of Physical Therapy and of the booklet "Apparatus Accepted," and the examination of other therapeutic apparatus.

Consultants on audiometers and hearing aids, on artificial limbs, on roentgen ray apparatus and on radium and radon products have cooperated with the Council in connection with the formulation of standards, the preparation of articles and the consideration of apparatus in the respective fields.

The interference with radio communications by electromedical equipment was one of the important subjects coming before the Council. A joint meeting was held at which members of the medical profession, representatives of the manufacturers of electromedical equipment, of radio manufacturers and of other interested bodies, and officials of the Federal Communications Commission were present. Ways and means of solving the problems were considered but no definite action was taken.

The Council on Physical Therapy has revised the Handbook of Physical Therapy and brought it up to date. The booklet "Apparatus Accepted" has been revised and reprinted.

The Council has continued its investigation of and reporting on apparatus submitted and in some instances has investigated and reported on products not submitted.

The Chemical Laboratory

The A. M. A. Chemical Laboratory continued in its important work of cooperating with the Council on Pharmacy and Chemistry in the examination and elaboration of standards for a large number of new preparations or new forms of old preparations offered to the medical profession. It exercised careful scrutiny over all the brands of sulfanilamide submitted to the Council and has examined the products of twenty-two manufacturers. The sulfanilamide now on the market has been found to coincide closely with the standards which were elaborated by the A. M. A. Laboratory in 1937. A good portion of one chemist's time has been devoted to the problems pertaining to crystalline zinc insulin and amorphous insulin, both in the solid form and in solutions in ampules. Nicotinic acid, cevitamic (ascorbic) acid, thiamin chloride, riboflavin and carotene are examples of pure vitamins in crystalline form which have received close attention by the Laboratory. Other compounds of interest are mercurials combined with theophylline, certain estrogenic substances and a number of products containing vasoconstrictors, including ephedrine, propadrine, racephedrine, neosynephrin and their salts. The Laboratory has found it necessary to continue examination of the various dextrose solutions on the market. A number of revised tests and standards were prepared dealing with products included in New and Nonofficial Remedies. New barbiturate derivatives and new anes-

thetics have been carefully examined chemically; also a number of contrast substances for the purpose of aiding x-ray diagnosis. Bismuth preparations still demand a great deal of attention.

The Laboratory has examined a number of products for the Bureau of Investigation, which have either been reported in THE JOURNAL or are about to be reported.

Members of the Laboratory staff have appeared before a number of scientific societies and have contributed to their programs. Members of the staff have also cooperated with other departments of the Association in the preparation or criticism of material involving chemical considerations.

Councils' Committee on Contraceptives

The Councils' Committee on Contraceptives was organized by the Council on Pharmacy and Chemistry and the Council on Physical Therapy of the American Medical Association at the request of the House of Delegates. The membership of the Committee is as follows: Dr. Paul C. Cannon, Dr. Carl Henry Davis, Dr. A. U. Desjardins, Dr. E. M. K. Geiling, Dr. E. E. Irons, Dr. John H. Musser and Dr. H. B. Williams. Ex-officio members of the Committee include Dr. Sollmann, chairman of the Council on Pharmacy and Chemistry, Dr. Mock, chairman of the Council on Physical Therapy, Dr. Fishbein, Mr. Carter and Dr. Leech.

The Committee on Contraceptives has decided on a general policy of conservative action and will serve largely as a fact-finding body rather than as an advisory body. Recently a report was issued on the use of roentgen rays for contraceptive purposes. An article by Dr. Irving Stein entitled "Contraceptive Methods" has been approved for publication by the Committee. This is a comprehensive review of contraceptive devices which may be harmful. Others have been asked to prepare articles dealing with contraceptive practices.

Advisory Committee on Advertising of Cosmetics and Soaps

The Advisory Committee on Advertising of Cosmetics and Soaps has continued to pass on preparations on which its advice has been requested. There is no doubt that a decided change has been noted in the advertising of many of the cosmetic firms, owing in large measure to the advent of the new Food, Drug and Cosmetic Act but in small measure also to the activities of this Committee. The Committee has been called on for advice from many sources. Although the Committee has not published any articles over its name, it is pleased to report that many of the firms with which it has dealt have revised their literature completely and effectively. In the case of other firms the Committee has been obliged to inform them that their products are not acceptable for advertising in the pages of THE JOURNAL. In 1938 the membership of the Committee was increased by two and now consists of Dr. Harry E. Alderson, Dr. Joseph J. Eller, Dr. C. Guy Lane, Dr. Francis E. Senear and Dr. Bedford Shelmire, with the Editor of THE JOURNAL and the Director of the Division of Drugs, Foods and Physical Therapy.

Council on Industrial Health

GENERAL ACTIVITIES

During its first year of organized activity, the Council on Industrial Health has been obliged to devote a major share of its attention to problems of organization and to definitions of the scope of work which it should undertake. In both directions it has had assistance and encouragement from the other established agencies at headquarters. With a view to expediting the ordinary conduct of Council affairs, an office and staff have been organized, rules adopted and subcommittees formed, and a bulletin has been developed by means of which questions of policy may be promptly submitted to the Council. During the year the membership was increased to twelve by the addition of Drs. L. D. Bristol, Anthony J. Lanza and Clarence D. Selby, while one member, Dr. Morton R. Gibbons, resigned.

NOMENCLATURE IN INDUSTRIAL DISEASE

The Council early concluded that the terminology used in industrial medical practice was in large part unscientific, if not chaotic. Usages have been derived from a variety of sources—court decisions, legislative and administrative practice, pronouncements of industrial organizations, and proceedings of technical committees and their publications. It was the opinion of the Council that by reason of this widespread confusion the medical profession needed an analysis of current industrial medical parlance to provide common understanding and acceptance of meanings. A Committee on Nomenclature was appointed to study the problem from a broad point of view and to arrange for the publication of a compendium. In compiling this list and defining its terms, the committee intends to consult with all other interested agencies, including bureaus and councils of the American Medical Association, in order that all possible sources of accurate and competent information may be represented. The publication of this material in book form will provide the profession with a useful reference in a field that has not heretofore been adequately treated.

MEDICAL EDUCATION AND INDUSTRIAL HEALTH

The Council has been impressed by the scarcity of opportunities for training in industrial medicine and hygiene in all categories—undergraduate teaching, organized graduate courses and postgraduate education. The advice and assistance of the Council on Medical Education and Hospitals were solicited and the conclusion was reached that most of the early activities of the Council on Industrial Health could profitably be directed toward the improvement of educational opportunities. Communications have been received from all but two of the four year medical colleges regarding the present status of undergraduate teaching in industrial hygiene and from all known departments in schools of medicine and public health conducting organized graduate courses. Data have been collected and organized in useful form for demonstration and publication. As the study continues, plans will be formulated designed to impress educators with the need of making the profession generally aware of its responsibilities and of the magnitude of its potential contribution to the industrial health program. Likewise, in the conduct of its early survey in the educational field the Council has learned of teaching programs for other than professional participants in the industrial health field which it might profitably explore.

PRODUCTION OF AUTHENTIC LITERATURE

The issuance periodically of authentic articles was considered an important part of the Council's educational program. The first of a series of publications on silicosis has appeared. Arrangements are being made for the preparation and publication of a series of articles covering the administration and maintenance of an adequate industrial medical service, with particular emphasis on the special needs of small industrial plants.

FIRST ANNUAL CONGRESS ON INDUSTRIAL HEALTH

In January 1939 the Council conducted the first of a series of conferences on industrial health. The underlying note of the inaugural meeting was that the practicing physician must attempt to orient himself in a rapidly expanding field. The aims and accomplishments of other organized agencies were clarified and the character of industrial medicine appraised and its scope and interrelationships reemphasized and redefined. The Council considers that this meeting satisfactorily fulfilled its objectives and has gone on record as approving an annual congress as one of its regular educational functions.

CONTACTS WITH STATE ASSOCIATIONS

The Council has been in correspondence with officials of the constituent medical societies in an effort to develop means for regular correspondence and interchange of opinions, preferably by the formation of committees on industrial health in the state societies. In many states the desirability of this arrangement has been realized, and at present twenty-five state medical associations have organized such committees and a few others have signified their intention to cooperate with the Council in this way. In recognition of the importance of these relationships, the Council has appointed a Committee on State Associations, which will have the effect of coordinating the pronouncements and recommendations of the Council with the activities of the state groups.

CLEARING HOUSE OF INFORMATION

From the outset it has seemed important to the Council that some arrangement be made for the collection and evaluation of contributions to the literature on the etiology, diagnosis, treatment and prevention of hazards associated with occupation This activity was originally suggested by the Section on Dermatology and Syphilology As sources of authentic information improve it is confidently expected that the Council office will be in a good position to satisfy the requirements of physicians who are in need of help in the solution of industrial problems

REVIEW OF COMPENSATION LAWS

Throughout all the preliminary discussions which led to the creation of the Council on Industrial Health, considerable emphasis was placed on the desirability of uniformity in compensation practice in the various jurisdictions The determination of a sound approach to compensation activities has given the Council great concern In this regard special attention has been paid to the functions and accomplishments of other agencies of the American Medical Association which have studied and acted on these matters At present the conclusion reached is that the Council should concern itself primarily with standards and accomplishments of medical practice under workmen's compensation laws As one of its important objectives, the Council proposes to determine which of the administrative agencies in charge of workmen's compensation now employ suitable medical representation and in what directions such medical boards could be expanded and their value emphasized

RELATIONSHIP OF TRAUMA TO DISEASE

Certain instances have come to the attention of the Council in which industrial commissions or courts have ignored or superseded commonly accepted scientific principles and knowledge in making awards, particularly through associating organic pathologic changes with previous trauma or by ascribing aggravation of preexisting disease to trauma It is not safe to assume that any action taken by a scientific organization will influence these administrative agencies It is the opinion of the Council, however, that an appraisal or medical survey of the relationship between trauma and disease, approached primarily from the point of view of the pathologist, might constitute a more reliable groundwork of reference which such tribunals ultimately could not ignore As a preliminary step in this direction the Council has suggested a cooperative survey with the Section on Pathology and Physiology of the Scientific Assembly regarding the relationship between trauma and appendicitis

REHABILITATION

The Council has been invited to participate in discussions covering the several aspects of vocational rehabilitation Conferences will probably be called soon looking toward improvement in the contributions of all agencies involved—the rehabilitation groups, the compensation commissions and the medical profession The Council has been disinclined to assume the initiative in developing conversations designed to clarify and improve the functions of these agencies until a greater degree of information is available, especially on the proper interest which medicine has in the total rehabilitation picture It is in this phase of the problem that the Council is most likely to interest itself for the time being, in view of its opinion that rehabilitation is not a medical function beyond the provision of adequate medical treatment from the inception of the injury

MEDICAL ORGANIZATION IN INDUSTRY

Sound opinion concedes that the next great impetus given the industrial health movement will be an effort to provide the employee in the small plant with the same advantages of controlled working environment and scientific preventive medicine as now exist in many of the larger establishments If this trend is substantially realized, many physicians will be called on to undertake, at least as a part time activity, preventive medical control over small manufacturing plants Satisfactory results will depend in large measure on the degree to which these physicians have comprehended the fundamentals of industrial hygiene and their practical application of this knowledge It is the plan of the Council therefore to aid in every ethical way the development of such services to small industries Arrangements for extension courses and postgraduate education through the state and county medical organizations will be emphasized The published reports of the Council will stress the functions of medical organization in industry, the material being so developed as to be ultimately available as a handbook for physicians and industrial executives

ACTIVITIES OF INDEPENDENT AGENCIES

Many physicians realize the widespread interest in the industrial health movement, but few are aware of the full extent of its complexity and ramifications There are more than 2,000 trade associations, not a few of which have developed programs for safety and for the elimination of hazards either individually or through established foundations Dozens of manufacturing concerns, particularly insurance carriers, have in the same fashion supported such enterprises as laboratory and field investigations, code development, determination of safe concentrations of toxic agents and health education in general Federal and state departments of labor, labor organizations and workers individually are demonstrating increasingly widespread interest in conditions of employment During the past several years the United States Public Health Service has expanded its facilities for investigation and control of occupational hazards and has fostered the development of bureaus of industrial hygiene in state departments of health and in a few cities The Council foresees as the basis of one of its most useful functions an ability to inform the profession about the spread of the industrial health movement and to correlate its own program with the programs of independent agencies which have obviously a real interest in and important contributions to make to improved health for the worker

Summary

The Council on Industrial Health has completed its first year of organized activity and much attention has been directed to internal organization and scope. The establishment of a headquarters office and a bulletin have greatly facilitated the conduct of its affairs. Preliminary work designed to introduce order into the chaotic field of industrial medical nomenclature is approaching completion. Plans are under way to create an abundance of opportunities for sound instruction in the fundamentals of industrial hygiene designed for the undergraduate medical student and for the postgraduate education of physicians. Contacts have been established with all the constituent associations, and committees of industrial health have been established in most of the states where the degree of industrialization seems to warrant it. Steps have been taken to make available authoritative information on clinical and administrative phases of industrial health. Ramifications of medical relationships under workmen's compensation are realized and the Council will work toward uniformity of administration and elevation of medical standards. The Council has instituted an investigation into the relationship between trauma and appendicitis. Its cooperation has been invited to determine the degree of medical interest involved in vocational rehabilitation. Independent agencies interested in industrial health have been investigated and activities of those which have important contributions to make to the health of the worker will be brought to the attention of the medical profession.

Bureau of Legal Medicine and Legislation

FEDERAL LEGISLATION

Seventy-Fifth Congress — The Seventy-Fifth Congress adjourned June 16, 1938 The Federal Food, Drug and Cosmetic Act had then passed both houses On June 25 it was approved by the President The act does not become wholly effective until the expiration of one year after the date of its approval, but its provisions relating to new drugs became effective immediately An analysis of the act was published in THE JOURNAL, July 23, 1938, pages 324-326

During the closing days of the Seventy-Fifth Congress, a bill was passed to amend the United States Employees' Compensation Act so as to give osteopaths the same status under that act as is given to doctors of medicine It was approved

by the President May 31, 1938. The passage of this bill can probably be attributed to a statement on the floor of the Senate that the medical profession had withdrawn opposition to it. No one authorized to speak for the Association had made any such representation and in fact the bill was as obnoxious as ever. The facts surrounding the passage of the bill were set forth in detail in THE JOURNAL, May 28, 1938, page 1838.

Seventy-Sixth Congress.—The Seventy-Sixth Congress convened in its first session Jan. 3, 1939. Already, when this report is being written, March 24, 1939, more than 7,500 bills and resolutions have been introduced and the session is still in progress. Even allowing for the introduction of identical bills in both houses, the volume and diversity of the legislation proposed is flowing, but it is probable that much of it will not be enacted. Abstracts of bills that seem to be of medical interest have been published weekly in THE JOURNAL. Among such bills, the following appear to call for special comment:

Wagner Amendment to Social Security Act.—Senator Wagner of New York introduced on February 28 a bill, S. 1620, proposing to expand the Social Security Act so as to give life to the recommendations of the Interdepartmental Committee to Coordinate Health and Welfare Activities, appointed by the President in August 1935. This bill is sometimes referred to as "The Wagner Bill," although its sponsors have selected for it, if it passes, the title "The National Health Act of 1939." The title is obviously adroitly chosen. This bill was referred to the Senate Committee on Education and Labor, where it is pending when this report is being prepared.

While no companion bill has been introduced in the House of Representatives, yet the recommendations of the Interdepartmental Committee to Coordinate Health and Welfare Activities are before the House, having been transmitted by the President Jan. 23, 1939, with the recommendation that they be given a careful study by the Congress. (H. R. Doc. No. 120, 76th Congress, first session.) In the House, the President's message and the report of the Interdepartmental Committee were referred to the Committee on Ways and Means, but up to present writing no action has been taken with respect to them. The essential difference between the situation in the Senate and the situation in the House of Representatives is that the Senate has before it the Wagner bill, proposing specific amendments to the Social Security Act to carry into effect the recommendations of the Interdepartmental Committee, while the House of Representatives has before it only the President's message and the report and recommendations of the Interdepartmental Committee and is left to formulate such legislation, if any, as it deems proper to give effect to those recommendations.

An analysis of the Wagner bill proposing amendments to the Social Security Act, looking toward the extension of medical and health services throughout the United States under the direction and supervision of the United States Public Health Service, the Children's Bureau and the Social Security Board, was published in THE JOURNAL March 11, 1939. Essentially, the bill proposes to provide federal subsidies to induce the several states to undertake new activities and to enlarge activities already under way, in certain economic, health and medical service fields named in the bill. The funds to be paid by the federal government toward the state activity are to be matched to a certain extent by funds appropriated by the state. The bill does not propose any specific taxes to cover the cost of the new and enlarged services but leaves the very large expense proposed by the bill to be met by increases in the general taxes or else by savings to be effected by the federal and state governments through the discontinuance or limitation of various federal and state services already under way.

The principal changes in the Social Security Act proposed by Senator Wagner's bill, of medical interest, include the following:

The Social Security Act provides federal subsidies to enable states to extend and improve "services for promoting the health of mothers and children." The pending bill proposes to authorize greatly increased subsidies to be allotted to the states to enable them not only to promote the objects provided for in the existing law but also to "provide medical care during maternity and infancy, including medical, surgical, and other related services, and care in the home or institutions, and facilities for diagnosis, hospitalization, and after care."

The Social Security Act provides for federal subsidies to enable the states to extend and improve services for locating crippled children and for providing medical, surgical, corrective and other services and care, and facilities for diagnosis, hospitalization and after-care for children who are crippled or who are suffering from conditions which lead to crippling. The pending bill proposes to enlarge the coverage to include an extension and improvement of services, supplies and facilities for the medical care of all children, especially children physically handicapped from any cause who are in need of special care.

The Social Security Act authorizes federal subsidies to aid the states, counties, health districts and other political subdivisions to establish and maintain adequate public health services, including the training of personnel for state and local health work. The pending bill proposes to permit allotments only to states and to authorize specifically the making of such allotments "to extend and improve public health work, including services, supplies and facilities for the control of tuberculosis and malaria, for the prevention of mortality from pneumonia and cancer, for mental health, and industrial hygiene activities" and for the development of more effective measures for carrying out such purposes, including the training of personnel. The Social Security Act furthermore authorizes a federal appropriation for expenditure by the Public Health Service for investigation of disease and problems of sanitation. The pending bill proposes to increase this appropriation and to authorize the Public Health Service, through the National Institute of Health, to make investigations of health, disease, sanitation and matters pertaining thereto.

Over a period of three years the pending bill contemplates an increase in federal expenditures of $196,550,000, exclusive of expenditures for administrative purposes, over the expenditures authorized by the Social Security Act for maternal and child health services, for services for crippled children and for public health work. What the increase in expenditures thereafter will be cannot be determined from the pending bill, because after 1942 no definite amounts are authorized, only as much as may be necessary.

The Social Security Act contains no authorization for appropriations for grants to states for hospitals and health centers. The pending bill proposes to add a new title to the act whereunder grants will be made by the Public Health Service to assist states to establish and improve hospitals and to assist, for a period of three years, in defraying the operating costs of added facilities. For the establishment and improvement of general hospitals the bill contemplates a federal appropriation of $8,000,000 for the fiscal year ending June 30, 1940, of $50,000,000 for 1941, of $100,000,000 for 1942 and of such sums "as may be necessary" thereafter. For mental and tuberculosis hospitals the bill proposes annual federal appropriations of such sums as may be necessary. Within the provisions of the bill, the term hospital is to include health, diagnostic and treatment centers, institutions and related facilities.

The Social Security Act does not authorize any appropriation to assist the states to extend and improve medical care generally. The pending bill does. It contemplates the addition of a new title to the Social Security Act whereunder grants may be made by the Social Security Board to the states to enable them to extend and improve medical care, including all services and supplies necessary for the prevention, diagnosis and treatment of illness and disability, and to develop more effective measures for carrying out the purposes of the new title, including the training of personnel. For the fiscal year ending June 30, 1940, an appropriation of $35,000,000 is to be authorized for this purpose and thereafter such sum annually as may be necessary.

The Social Security Act does not contain any authorization contemplating cash payments by the states to individuals who are temporarily disabled from whatever cause. The pending bill would add to the act a new title to authorize grants by the Social Security Board to assist the states in the development, maintenance and administration of plans for paying compensation to persons temporarily unable to or unfit for work by reason of injury or illness not arising out of or in the course of employment. For the fiscal year ending June 30, 1940, the sum of $10,000,000 is to be authorized and thereafter such sum annually as may be necessary. No state may, how-

ever, receive any of the federal funds unless it has a plan or plans that have been approved, presumably by the Social Security Board, under which the board finds that "reasonably adequate medical services, including preventive services, are available to minimize disability among those covered under the state plan for temporary disability compensation."

The Wagner Social Security Act amendment bill was discussed editorially in THE JOURNAL, March 11, 1939, as follows:

The House of Delegates of the American Medical Association, in considering the National Health Program, approved expansion of public health service where need could be shown, approved medical care to the indigent and to the medically indigent where need could be shown, and approved even expansion of hospital construction, provided the need could be demonstrated, recommending, however, utilization of existing facilities to the utmost before a new building program was authorized. The House of Delegates also approved the principle of assistance to the worker for temporary disability resulting from illness. Now the Wagner act goes far beyond these recommendations: First, it authorizes the expenditure of vast sums before the need has been shown; second, it expands tremendously the work of the Children's Bureau, the United States Public Health Service and the Social Security Board, without any demonstration that such expansion is warranted; third, it proposes to place the state health officers in a commanding position as far as concerns the dispensing of the funds allotted, subject only to approval of all plans by the federal agency to which the task is assigned. Vast funds are provided for the construction of hospitals and health centers and for their maintenance, notwithstanding the fact that there is not yet available any dependable determination of the exact nature and extent of needs that prevail. Who can imagine for a moment that the money once appropriated will not be expended? Finally, the measure introduces the principle of allotment of federal money to the individual states for medical care, by the Social Security Board, without specifying the means to be used in the individual states for providing such service other than to demand the approval of the Social Security Board.

As is emphasized in the analysis made by the Bureau of Legal Medicine and Legislation, the advisory councils to be set up are vague as to their membership, their duties and their responsibilities. There is one criticism that is to be made above all others in relation to this proposed legislation, namely its extreme vagueness in the light of the vast sums of money to be dispensed and the great powers conferred on certain federal officers in the control of the spending, and particularly the decision as to which of the individual states shall benefit by the expenditures.

Health Insurance.—A health insurance bill entitled "A Bill to aid in alleviating the loss caused by sickness," S. 658, was introduced by Senator Capper of Kansas, identical with a bill introduced by him in the Seventy-Fifth Congress. It proposes to authorize annual federal appropriations of $200,000,000 to induce the several states to develop and maintain systems of health insurance. The bill follows closely the provisions of the so-called Epstein health insurance bill. It is pending, when this report is being written, in the Senate Committee on Finance.

Tuberculosis.—A bill introduced by Senator Murray of Montana, S. 471, proposes to authorize an appropriation of $5,000,000 immediately and during the next succeeding four fiscal years unlimited annual appropriations to assist the several states in providing hospital beds for tuberculous persons. Under the provisions of the bill the federal government is to pay to each state which has submitted to the Surgeon General of the Public Health Service plans satisfactory to him 75 per cent of the cost of providing additional hospital beds and in addition a sum not to exceed $1.25 a day per bed actually operated. A state, to obtain the federal subsidy, must appropriate a sum equal to 25 per cent of the total amount required to provide the added hospital beds, and the state or a political subdivision of it must pay at least 50 per cent of the cost of operation. This bill is pending in the Senate Committee on Commerce.

Narcotic Drugs.—A joint resolution to authorize a survey of narcotic conditions in the United States by the United States Public Health Service, H. J. Res. 103, was introduced by Representative Coffee of Washington and is pending in the House Committee on Interstate and Foreign Commerce. It proposes to authorize the United States Public Health Service to investigate the conditions in the United States "existing now and during the past twenty-five years with respect to the importation, production, distribution, and use of narcotics," in order to obtain information with respect to (*a*) the extent of unlawful activities in narcotics, and the number of persons connected with such activities; (*b*) the extent of addiction to the use of narcotics, the number of addicts, the causes of addiction, the availability and use of various kinds of treatment, and other related matters; and (*c*) the conditions and trends with respect to the prevalence of evils arising from narcotics, with a view to aiding Congress to enact laws and aiding the law enforcement agencies to administer the laws, so as properly to protect the people from such evils. The Surgeon General of the Public Health Service is to report the results of his investigation to Congress, if this joint resolution is enacted, and he is to recommend any necessary legislation.

Medical Care for Transients or Nonresidents.—Two bills, H. R. 2974 and H. R. 2975, were introduced by Representative Voorhis of California proposing to amend the Social Security Act so as to authorize the appropriation of federal funds to assist the states to provide medical care for nonresident needy persons or for needy transients. Both bills are pending in the House Committee on Ways and Means.

Epilepsy.—The creation of a National Epilepsy Institute in the United States Public Health Service is proposed in S. 1557, introduced by Senator Shipstead of Minnesota. This bill, still pending in the Senate Committee on Commerce, is modeled closely after the National Cancer Institute Act, passed by the Seventy-Fifth Congress. It proposes to authorize the institute to conduct researches, investigations, experiments and studies relating to the cause, diagnosis and treatment of epilepsy, to assist and sponsor similar research activities by other agencies, public and private, and to promote the coordination of all such researches and activities and the useful application of their results, with a view to the development and widespread use of the most effective methods of prevention, diagnosis and treatment of epilepsy.

Cancer.—Representative Rogers of Massachusetts has introduced a bill, H. R. 4585, proposing to amend the National Cancer Institute Act so as to authorize an additional appropriation of $2,300,000 for the fiscal year ending June 30, 1940, and unlimited appropriations annually thereafter, to assist states, counties, cities or other political subdivisions to extend and improve measures through public and private institutions and organizations for the diagnosis, treatment and control of cancer, including the provision of hospital, diagnostic, clinic and other facilities for the diagnosis and treatment of persons suffering from cancer or suspected of suffering from that disease.

Financial Aid to the Disabled.—Nine bills, in addition to the Wagner amendments to the Social Security Act, propose to amend that act so as to provide federal funds to assist states to make cash payments to individuals who are physically disabled. None of these bills propose that medical services be supplied. Under the provisions of five of the bills, H. R. 42, H. R. 1960, H. R. 3999, H. R. 4035 and S. 1218, a person must be permanently disabled before he is entitled to the contemplated benefits of the bill. The other bills, H. R. 172, H. R. 2000, H. R. 2753 and H. R. 5038, make a physical disability or handicap a condition precedent to the receipt of benefits but are not clear as to such disability or handicap being permanent. All the House bills are pending in the House Committee on Ways and Means. The Senate bill is before the Senate Committee on Finance.

Deduction of Medical Expense Under the Income Tax Law.—Two bills have been introduced by Representative Tenerowicz of Michigan proposing to permit federal income taxpayers to deduct in the computation of their income taxes amounts expended during the taxable year for medical services. One bill, H. R. 4747, places a limit of $500 on the amount that may be so deducted; the other, H. R. 4779, imposes no such limit. Both bills are pending in the House Committee on Ways and Means.

Food, Drug and Cosmetic Act.—Under the new Federal Food, Drug and Cosmetic Act a drug that enters into interstate commerce or commerce in the District of Columbia or other jurisdiction under exclusively federal control must be labeled so as to show its common name or, if it is fabricated of two or more ingredients, its several ingredients. Drugs intended for use by man and containing any quantity of certain narcotic or hypnotic habit-forming substances must be labeled "Warning—May be habit forming." Drugs dispensed on written bona fide prescriptions of physicians, dentists and

veterinarians are under certain conditions exempted from these labeling requirements, except that a drug dispensed in the course of the conduct of a business of dispensing drugs pursuant to diagnosis by mail is not so excepted. This requirement becomes effective June 25, 1939. How many nostrums are sold on the basis of actual diagnoses by mail is not known. The provisions of the new law, however, seem to threaten with particular force one of them, Dr. Nathan Tucker's Asthma Specific, a preparation exploited primarily for the relief of asthma. The preparation is used as a spray and is labeled as containing variant quantities of cocaine per fluidounce, from 5 grains upward, although the proprietors of the nostrum claim that when it reaches the consumer it contains only minute quantities of cocaine, the residue having been converted into ecgonine. Whether it contains any other potent ingredients is not known.

Legislative relief is being sought by the proprietors of Dr. Nathan Tucker's Asthma Specific through H. R. 3951, a bill that proposes to exempt from the requirements that apply to nostrums sold on the basis of diagnoses by mail "a drug prescribed or dispensed by a physician pursuant to a diagnosis made from oral or written information given by the patient and where such drug is not dangerous to health and has been effective in relieving the condition for which it is prescribed in at least one thousand cases per year during the last twenty years preceding the approval of this Act." The effect of the enactment of this bill would be to give to the proprietors of Dr. Nathan Tucker's Asthma Specific a chance to show that cocaine is not dangerous to health or to show that it contains no cocaine and therefore, if labeled as containing cocaine, that it is misbranded under the law; also to show that the extensive use of their nostrum is not due to the habit forming properties of the cocaine put into it or of any derivative of that cocaine. This bill is pending in the House Committee on Interstate and Foreign Commerce.

Social Security Act and Scientific and Educational Organizations.—A bill is pending in the House of Representatives Committee on Ways and Means, H. R. 101, introduced by Representative O'Day of New York, proposing to bring under the old age and unemployment benefit provisions of the Social Security Act organizations operated exclusively for religious, charitable, scientific, literary or educational purposes, and the employees of such organizations. Such employees and their employers will, if the bill is enacted, become subject to the taxes imposed by the act and entitled to such benefits as the act may provide. According to present information, the House Committee on Ways and Means has decided to postpone indefinitely action on this proposed amendment to the Social Security Act, notwithstanding the fact that it has the approval of the Social Security Board.

Legislation Relating to Veterans.—The Seventy-Fifth Congress authorized the House Committee on World War Veterans' Legislation to make a comprehensive survey and inspection of soldiers' hospitals and other Veterans' Administration facilities, including hospitals with which the government has a contract for ex-service men of any war in which the United States was engaged. This investigation was made and a report submitted to the House of Representatives, Jan. 30, 1939. The committee reported that the Veterans' Administration is maintaining a high standard in care and treatment of beneficiaries and is continually studying new diagnostic and treatment methods which may benefit the disabled American veteran. From the contents of the report it would seem that the investigation was primarily for the purpose of inspecting the physical equipment of the various hospitals and the manner in which they are operated. The report contained no recommendation as to the need of additional hospitals. Concerning the number of veterans in such hospitals, the report stated:

> Of the 50,670 veterans under treatment at the end of last year, 47,285 were in facilities controlled by the Veterans' Administration; 2,512 in other Government hospitals; and 873 in State or civil institutions. Over 63 per cent of these veterans in all hospitals are receiving treatment in the facilities in the State of their reported home addresses. Since March 3, 1919, when the acquisition of the Government hospitals was first authorized for the treatment of veterans of the World War, there have been 1,863,289 admissions of veterans of the United States to hospitals, of which 152,966 were made during the last year. This load has been increasing since 1919.

As of June 30, 1938, there was in Veterans' Administration facilities a total of 51,991 hospital beds, apportioned to the different classes of patients, as follows: neuropsychiatric, 28,119; tuberculosis, 5,121; general, 11,662; general: homes, 7,089. During the fiscal year 1939 it is proposed to add 3,453 new beds, as follows: neuropsychiatric, 1,334; tuberculosis, 155; general, 1,012; general: homes, 952. During the fiscal year 1940 it is proposed to add 6,731 new beds, as follows: neuropsychiatric, 3,686; tuberculosis, none; general, 2,653; general: homes, 392. If the proposed plans are carried out, there will be available, as of June 30, 1940, a total of 62,175 beds in Veterans' hospitals, as follows: neuropsychiatric, 33,139; tuberculosis, 5,276; general, 15,327; general: homes, 8,433. The present hospital building program of the Veterans' Administration is being carried out under an appropriation of only $4,500,000 made available directly by the Seventy-Fifth Congress, but this is being supplemented by a sum three times as large, $13,268,200, donated by the Public Works Administration.

The Administrator of Veterans' Affairs contemplates as an ultimate goal 100,000 beds in Veterans' hospitals, which will make available one bed for every forty veterans throughout the United States. He estimates that the peak load of hospitalization will be reached in 1949 or 1950. What is to become of these hospital facilities as that load declines is not clear, especially in view of the proposal in the pending Wagner bill to amend the Social Security Act that, if the bill should be enacted, may increase the number of beds in government hospitals in the United States within the next three years by as many as 79,000 beds. With an average of 31.1 per cent of the beds in the general hospitals of the United States unoccupied in 1938, the need for any such enlarged hospital program is not apparent.

It is impracticable to discuss in detail the provisions of the various bills now pending in the Seventy-Sixth Congress, proposing to construct either new hospitals or additions to existing facilities. There are pending, however, twenty-one bills proposing (1) to make available a minimum of 2,409 additional beds specifically designated for general medical and surgical disabilities, (2) to construct six new hospitals, with a combined minimum bed capacity of 2,750 beds, for the accommodation of veterans suffering from any type of disability for which they are entitled to hospitalization, (3) to construct a hospital of 200 bed capacity to accommodate veterans suffering from diseases of the chest, (4) to construct a neuropsychiatric hospital to accommodate 400 patients and (5) to construct a 300 bed addition to take care of general medical, surgical and neuropsychiatric disabilities. No action has been taken on any of these bills yet. One of the bills is pending in the Senate Committee on Finance. All others are before the House of Representatives Committee on World War Veterans' Legislation.

Contract and Acting Assistant Surgeons, Spanish-American War.—The injustice that has been done contract surgeons of the Spanish-American War in the matter of pensions continues. As has been previously reported to the House of Delegates, women nurses who served under contract as army nurses in the active military service of the United States during the Spanish-American War are entitled to service pensions; that is, pensions granted them because of disability incurred other than in the line of duty or because of advancing age. Contract women nurses are therefore placed on a parity with the commissioned and enlisted personnel. Contract surgeons, on the other hand, are denied service pensions and remain in a class by themselves. There are pending two bills, S. 259, introduced by Senator McNary of Oregon, and H. R. 2540, introduced by Representative Smith of Washington, which propose to accord contract surgeons of the Spanish-American War the same rights to pensions as are now accorded persons who served in the war under a similar status. These bills are pending, respectively, in the Senate and House Committees on Pensions.

Federal Department of Health.—Three bills are pending proposing to authorize the reorganization of the civil administrative agencies of the executive branch of the government: S. 1706, introduced by Senator Byrd of Virginia, H. R. 4425, introduced by Representative Cochran of Missouri, and H. R. 4893, introduced by Representative Angell of Oregon. None

of these bills, however, either provide for the establishment of a federal department of health or contain any authorization whereby such a department may be created. All three bills, on the other hand, definitely preclude the creation of any new department in any reorganization scheme that may eventuate from them. On March 6, however, Representative Pfeifer of New York introduced a bill, H. R. 4791, proposing the establishment of a federal executive department of health, with a secretary of health at its head, appointed by the President from the medical profession, with the advice and consent of the Senate. The duty of the new department would be to protect and maintain health and sanitation by (1) conducting research, experiments and surveys, formulating and fostering plans, and compiling and disseminating information; (2) performing such other functions relating thereto as shall be authorized by law, and (3) cooperating with official agents established by law in the several states and subdivisions thereof. To this federal department of health would be transferred the Food and Drug Administration of the Department of Agriculture; the Bureau of Census, Division of Vital Statistics, of the Department of Commerce; the Freedman's Hospital and St. Elizabeths Hospital of the Department of Interior; the Children's Bureau of the Department of Labor; and all functions of the Public Health Service and the Bureau of Narcotics, now operating under the Treasury Department, and the Health Department of the District of Columbia. Furthermore, the President would be authorized at any time within ninety days after the passage of the act to transfer to the new department the whole or any part of any bureau, service or other agency of the government primarily engaged in fostering and promoting health and sanitation. The Secretary of Health, according to the provisions of the bill, will be authorized, with the approval of the President, to reorganize or consolidate any of the bureaus, services or offices under his jurisdiction, redistribute the functions thereof, or set up in the Department of Health such subdivisions as may best be adapted for accomplishing the purposes for which the department is to be established. The bill is pending in the House Committee on Expenditures in the Executive Department.

United States Postgraduate Medical and Surgical College.—A bill, introduced by Representative May of Kentucky, H. R. 2423, proposes to establish a United States Medical and Surgical College to be located in the District of Columbia. This bill is identical with a bill introduced by the same author in the Seventy-Fifth Congress. It proposes to authorize an appropriation of $10,000,000 to construct and equip necessary buildings and the appropriation annually of such sum as may be necessary to carry out the purposes of the bill. Graduates of accredited medical and surgical colleges would be admitted to this so-called medical West Point for training for army, navy or public health work, on designation by Senators and Representatives in Congress. This bill is pending in the House of Representatives Committee on Interstate and Foreign Commerce.

Cooperative Medical Service.—A bill, H. R. 4312, introduced by Representative Hull of Wisconsin, proposes to amend the Code of the District of Columbia so as to provide for the organization and regulation of cooperative associations of various kinds. An association organized under the bill would be authorized to engage in any one or more lawful modes of acquiring, producing, operating, furnishing, exchanging and distributing any type or types of services for the primary and mutual benefit of the patrons of the association, and of the patrons of such patrons, if any, as ultimate consumers. The bill proposes that an association formed under the act which arranges for the rendering to its members of licensed professional services on a nonprofit basis shall not be subject to the insurance laws nor be construed as being in violation of any rule against corporate practice of professions or in violation of statutes regulating licensure of professions. Any group incorporated under any other law of the District of Columbia and operating on a cooperative basis or any unincorporated group operating on such a basis in the District of Columbia is to be authorized to secure the benefits proposed by this bill if it desires to do so. No association, or method or act thereof, which complies with the provisions of the bill is to be deemed a conspiracy or a combination in restraint of trade or an illegal monopoly, or an attempt to lessen competition or fix prices arbitrarily. This bill was referred to the House of Representatives Committee on the District of Columbia, where it is now pending.

STATE LEGISLATION

Through a legislative reporting service, the Bureau of Legal Medicine and Legislation receives daily when any state legislature is in session notices of bills of interest to the medical profession that have been introduced. Ordinarily such notices are received about the third day after the introduction of the bill and report only its number and title, its sponsor and the committee to which it has been referred. Obviously, a state medical association that maintains its own legislative service at the state capital or has its headquarters there usually obtains such information before the Bureau of Legal Medicine and Legislation in Chicago, but most of our state associations are not so fortunately situated. The Bureau, therefore, immediately on receipt of notice that a bill has been introduced reports its introduction to the president, the secretary and the chairman of the legislative committee of the state association immediately concerned. This reporting in triplicate enables the officers named to confer among themselves at once, even though located at more or less remote places, to determine the policy of their association with respect to the measure.

As soon as possible after the introduction of a bill, the legislative reporting service supplies a copy of it, and it is then analyzed by the Bureau in the light of the laws already in force in the state and of the policies of the American Medical Association. If the analysis shows anything of moment, a letter stating the facts is immediately sent to the secretary of the association, copies of which are sent to the president and the chairman of the legislative committee, for their guidance. In any event, an abstract of each bill that is deemed of interest to the profession in the particular state is submitted to THE JOURNAL for publication and published so far as available space in THE JOURNAL permits, so that every Fellow of the Association and every subscriber to THE JOURNAL may know what legislation is pending in his own state. In this way, interested Fellows and members of the Association in every state, and subscribers to THE JOURNAL, learn what is going on more promptly than would otherwise be possible, for the state journals, with only two exceptions, appear only monthly whereas the service rendered by the Bureau, through THE JOURNAL, is weekly. A similar service is rendered as the bill progresses toward defeat or enactment; the Bureau receives from its legislative reporting service reports of action by committees and by either branch of the legislature and of the enactment or defeat of the bill, if it reaches a final vote. As has been pointed out, although a few state medical associations are so highly organized and fortunately situated as not to be in need of such service as is described, to a large number of such associations the service seems to be of value.

After the close of each calendar year, the legislation that has been considered by state legislatures that met during the year is summarized and the result published in THE JOURNAL, to keep the medical profession of the country informed of the trends of legislation and legislative opinion in the various legislative fields of medical interest. The summary of state legislation for 1938 was published in the Organization Section of THE JOURNAL, Feb. 11 and 18, 1939. A brief discussion of some of the most important state legislation considered during 1938 follows.

Laws Relating to the Healing Art.—A new Massachusetts law postponed until Jan. 1, 1942, the effective date of a law enacted in 1936, which was to raise the educational qualifications exacted of applicants for licenses to practice medicine by requiring such applicants to have completed two years of premedical collegiate work and to have graduated from a chartered medical school approved by the secretary of the board of registration and medicine, the commissioner of education and the commissioner of public health. Laws were enacted in Mississippi and New York setting out causes for the revocation, suspension and refusal of licenses in addition to the causes enumerated in the prior laws. An osteopathic practice act passed in South Carolina and osteopaths are now licensed by an unsupervised and uncontrolled board of osteopathic examiners. A resolution was adopted in Massachusetts directing a special unpaid commission to investigate the advisability of establishing an independent board of examination and registration in osteopathy and a similar board in chiropractic.

Contraception and Venereal Disease Prophylactics.—A new Kentucky law prohibits the retail sale or distribution of appliances, drugs or medicinal preparations intended or having special utility for the prevention of venereal diseases, except by licentiates of the state board of pharmacy and licentiates of the board of medical examiners regularly licensed to practice medicine.

Laws Designed to Combat Syphilis.—Laws were enacted in New Jersey, New York and Rhode Island to require every physician attending a pregnant woman to take a sample of her blood and to make or cause to be made a standard serologic test for syphilis. Laws to require, as a condition precedent to the issue of marriage licenses, that both parties to the proposed marriages present certificates from physicians that they are free from stated venereal diseases were enacted in Kentucky, New Jersey, New York and Rhode Island.

Compulsory Health Insurance.—Bills proposing the establishment of systems of compulsory state health insurance were considered in 1938 in Massachusetts, New York and Rhode Island, but all these bills failed of enactment. All were patterned closely after the so-called Epstein social security bill for health insurance. However, a new New York law created a state commission to study and recommend ways and means of minimizing risks of illness through the extension of public health services; for furnishing adequate medical care for persons of low income, which have to be met from public funds; for making public funds available for the support of medical education and for studies for raising the standards of medical practice; for medical care to the indigent; for using private institutions in allocating public funds for the rendition of medical service to the public; for effecting adequate administration and supervision of the health functions of the state government, and, if deemed advisable, for consolidating under a separate department all federal and state health and medical services and activities. This commission was directed to report to the legislature before Feb. 15, 1939, but the New York legislature in 1939 was asked to extend its existence for another year for the purposes stated.

Hospital Service Corporations.—Laws were enacted in Kentucky and New Jersey authorizing the formation of corporations to provide on a so-called "nonprofit basis" "hospital care" to their members or subscribers. The activities of such corporations under these laws would seem to be limited to the rendition of hospital care and not to include medical or surgical care. A new Louisiana law provides for the formation of so-called service companies, authorized to make agreements with members or subscribers to furnish hospitalization and incidental drugs on the occurrence of sickness or other physical disability of a member or subscriber. Whether such companies may also contract to furnish medical care is not clear from a perusal of the law.

Narcotic Drugs.—The uniform narcotic drug acts in force in Louisiana and New Jersey were so amended in 1938 as to make cannabis or marihuana a narcotic drug within the meaning of the acts. The New York uniform narcotic drug act was so amended as to redefine cannabis.

Vaccination.—A new Virginia law authorizes local boards of health, in addition to rights previously possessed at law, to require, whenever they deem it necessary to prevent an epidemic, the compulsory administering of toxoids.

Workmen's Compensation.—So far as can be ascertained, no workmen's compensation legislation of interest to the medical profession was enacted in 1938.

Pneumonia Control Program.—A total of $35,000 was appropriated in New Jersey for the purchase and distribution of type I and type II pneumonia serum to be available free of charge to persons afflicted with pneumonia and financially unable to purchase the necessary serum.

STATE LEGISLATION BY INITIATIVE

In some states, chiefly in the West and Southwest, the constitution permits the electorate to enact legislation directly through their votes at the polls and not through the legislature, a process that is commonly referred to as the initiative. Sometimes procedures have been instituted under the initiative to accomplish purposes that would hardly have received serious consideration. The chiropractic and osteopathic initiative acts adopted in California by the initiative in 1922 illustrate this point. In recent years, cultists in states in which the procedure is possible have with increasing frequency resorted to the initiative to gain for themselves advantages that they could not have hoped to gain through the legislature.

In 1938 four initiative proposals were pending which, if adopted, would have jeopardized the public health and welfare in those states. Two of these measures were voted on at the general elections in November 1938. Fortunately neither was adopted.

In Colorado the electorate decisively rejected an initiative measure advanced by the chiropractors, which, while proposed by them primarily to protect themselves from regulation by the legislature, would have weakened the other laws of the state, those relating to the practice of the healing arts, and would have produced chaotic results in the fields of medicine and public health.

The California electorate rejected an initiative measure designed to hinder the use of living dogs for purposes of research. This measure proposed to forbid the delivery of any living dog from any pound in the state to any institution of learning or research for purposes of study or instruction.

In Oklahoma an initiative measure was inaugurated which proposed to amend the medical practice act so as to permit hospitals and clinics organized on a mutual or cooperative basis to enter into contracts for hospital or medical services and to prevent the board of medical examiners from disciplining licensed physicians who cooperated in such schemes. The people of the state, however, did not vote on this measure, since at the time of the election an appeal was still pending in the Supreme Court of Oklahoma to determine the regularity of the petition on the basis of which it was proposed to put the initiative measure on the ballot. A bill is now pending (March 22, 1939) in the Oklahoma legislature which, if enacted, will accomplish the results aimed at by the proposed initiative measure.

In Ohio a contemplated chiropractic initiative measure somewhat similar to the Colorado chiropractic initiative was considered, but its proponents never carried it to a point at which the electorate might pass on it. The cultist sponsors of this measure apparently became disheartened shortly after they had submitted it to the attorney general for his approval as to form and never offered petitions with a sufficient number of signatures to entitle the measure to a place on the ballot.

COOPERATION APPRECIATED

The Board of Trustees, on behalf of the Bureau of Legal Medicine and Legislation, expresses appreciation of the cooperation that the Bureau has received from the several state constituent medical associations and component county medical societies and from individual physicians.

Summary

Federal Legislation.—**Seventy-Fifth Congress: The new Federal Food, Drug and Cosmetic Act was approved by the President June 16, 1938, and the provisions of it relating to new drugs became effective immediately. The other provisions will become effective June 25, 1939. Under the provision of a law enacted by the Seventy-Fifth Congress, osteopaths are given the same status as doctors of medicine under the United States Employees' Compensation Act.**

Seventy-Sixth Congress: The Wagner bill to amend the Social Security Act proposes to give life to the recommendations of the Interdepartmental Committee to Coordinate Health and Welfare Activities. Essentially the bill proposes to provide federal subsidies to induce the several states to undertake new activities and to enlarge activities already under way in certain economic, health and medical service fields named in the bill. The Capper sickness insurance bill contemplates a federal appropriation of $200,000,000 annually to induce the states to develop and maintain systems of health insurance.

Other federal subsidies are proposed in pending bills to enable states to provide hospital beds for tuberculous persons, medical care for transients or nonresidents, financial aid to the disabled, and to improve measures for the diagnosis, treatment and control of cancer.

A survey of narcotic conditions is proposed in a pending measure, and the creation of a National Institute of Epilepsy similar to the National Cancer Institute is contemplated by another bill. Other federal proposals

would authorize federal income tax payers to deduct the amount expended for medical services and would amend the Federal Food, Drug and Cosmetic Act for the relief of a nostrum exploited for the relief of asthma.

A proposal to bring under the old-age and unemployment provisions of the Social Security Act organizations operated exclusively for religious, charitable, scientific, literary or educational purposes has been indefinitely postponed by the House Committee on Ways and Means.

The House Committee on World War Veterans' Legislation has filed a report of its investigation of veterans' hospitals but recommended no increase in beds. The present building program is being carried out with the aid of more than $13,000,000 obtained by the Veterans' Administration from PWA. Proposals continue to be made to Congress for the construction of new hospitals. The injustice that has been done to contract surgeons of the Spanish-American War continues.

Three bills propose the reorganization of the civil administrative agencies of the executive branch of the government but none provide for the establishment of a federal department of health or contain any authorization whereby such a department may be created. A pending bill, however, does propose the establishment of such an executive department with a secretary of health at its head. Another bill proposes the establishment of a United States Medical and Surgical College to be located in the District of Columbia, in which graduates of accredited medical and surgical colleges will be trained for army, navy or public health work.

The incorporation and the legalization of cooperative medical service organizations in the District of Columbia is contemplated by a pending bill.

State Legislation.—During the year, as it has done in prior years, the Bureau kept constantly in touch with state legislation of medical interest, promptly advising state associations of legislative proposals that seemed to be of particular importance Compulsory health insurance proposals were defeated in Massachusetts, New York and Rhode Island, but a commission was created in New York to study the matter and to report back to the legislature. Hospital service corporations were authorized in Kentucky, Louisiana and New Jersey. Other legislation enacted in one or more states related to osteopathy, chiropractic, venereal diseases, narcotic drugs, vaccination, pneumonia control, educational qualifications of applicants for licenses to practice medicine and the causes for which such licenses may be revoked.

State Legislation by Initiative.—Initiative measures in California and Colorado that would have jeopardized the public health and welfare of those states were decisively rejected by the people. Proposed initiative measures in Oklahoma and Ohio did not appear on the ballot.

Bureau of Health Education

By action of the House of Delegates at the San Francisco session, the name of the Bureau of Health and Public Instruction was changed to Bureau of Health Education This change was made in the interest of simplicity and to minimize the occurrence of erroneous identifications of the Bureau

CORRESPONDENCE

The correspondence handled through the Bureau continues to be divided into two main groups, which are called, for convenience, Bureau correspondence and Question and Answer correspondence The number of letters handled under each heading was Bureau, 5,474, Question and Answer, 8,220, Radio Audience Mail, 1,145 In Bureau correspondence an increase is noted of 17 per cent over 1937, the 1937 increase over 1936 was 13 per cent

Question and Answer correspondence in 1938 showed a decrease of 16 per cent, whereas in 1937 it increased 26 per cent over 1936 The 1938 decrease is accounted for by the absence of world's fairs or major expositions American Medical Association exhibits at such expositions always stimulate correspondence In 1937 fairs were in progress at San Diego, Dallas and Cleveland The normal unstimulated correspondence actually showed an increase in 1938 of 4 per cent over 1937

Radio audience mail can be controlled by the practice of asking or not asking for correspondence in connection with broadcasts The relatively small volume of audience mail in 1938 is due entirely to the fact that no inducements were offered to the radio audience

RADIO PROGRAM

The radio program Your Health, in cooperation with the National Broadcasting Company, was broadcast from January 1 through June 15 to complete the first series of special programs for schools A new series was authorized by the Board of Trustees early in 1938 and was put on the air beginning Oct 19, 1938 This was based on the same principle as the first series of special programs for junior and senior high schools Therefore, the radio briefs which had been published in HYGEIA from October 1937 through June 1938 were not republished, but listeners were referred to file copies of HYGEIA for these briefs and only a much abbreviated radio announcement was carried in HYGEIA each month from September through December 1938

The usefulness of this program to the schools was indicated by the fact that in the latter weeks of summer and the weeks of school openings numerous letters from school principals, health supervisors and science teachers were received asking information as to when the program would be resumed

Sixty National Broadcasting Company stations regularly broadcast the program

The Woman's Auxiliary gave its customary cooperation in publicizing the radio program locally, as did many state and county medical societies

The workbook "Your Health," published by the Johnson Publishing Company to coordinate with the program, was reissued in a 1938-1939 edition practically identical with the edition of 1937-1938

A broadcast on "Medical Care" was given over the Blue network of the National Broadcasting Company by Dr Irvin Abell, President of the Association, September 17, during the special session of the House of Delegates

The Your Health program received a first award from the Institute on Radio in Education at its ninth annual meeting in Columbus, Ohio, in May At this meeting transcriptions of broadcasts were heard by the Committee on Awards, and the superior quality of the Your Health program was recognized by this award

The radio library maintained by the Bureau for the use of state and local medical societies and of organizations whose use of the material is approved by local medical societies was called on by such organizations during 1938 for 5,540 scripts, as compared with 4,589 in 1937 and 3,388 in 1936 In 1938, 128 county medical societies used the scripts, as compared with seventy-two in 1937. In 1938, twenty-one state medical associations used the scripts, as compared with thirteen in 1937

In order to keep the script library up to date, 100 older manuscripts have been dropped and 123 new ones added, making a total of 876 titles, of which 351 are for fifteen minutes, 196 for ten minutes and 329 for five minutes

Advice and suggestions with regard to outside radio programs were given in sixty-two instances Among the most important instances of cooperation in 1938 was included the development of a radio broadcast complimentary to the medical profession by the famous radio team of Lum and Abner in which the Bureau was assisted by the executive secretary of the Los Angeles County Medical Association

A special dramatized broadcast on infantile paralysis was put on the air and transcribed for repeated local use on December 19 in cooperation with the National Broadcasting Company and the National Foundation for Infantile Paralysis, affiliated with the Committee for the Celebration of the President's Birthday

The evaluation project by the Committee on Evaluation of the Federal Communications Commission, with headquarters at Ohio State University, continued through the year. The evaluation was hampered during the last half of the year by the absence of a Chicago outlet for the program Your Health

PROTECTION OF RESEARCH

The Bureau has continued its cooperation with the Committee for the Protection of Medical Research under the chairmanship of Dr Elliott C Cutler

The Bureau made its usual donation in May to graduating medical students of complimentary copies of the pamphlet Animals in Research This was accompanied by a copy of the Bureau of Medical Economic's pamphlet Economics and the Ethics of Medicine The Animals in Research pamphlets distributed totaled 5,430, and the pamphlets on medical economics 5,342

COOPERATION WITH GOVERNMENTAL AGENCIES

The Bureau is frequently called on for advice, consultation and cooperation by public agencies, including departments of the federal government, state health and education departments and the health departments, school boards and libraries of municipalities The states and their subdivisions to which service has been extended are too numerous to list, but the federal departments and the divisions of these which have called on the American Medical Association for service through this Bureau alone are as follows

United States Department of Labor
Children's Bureau
United States Department of the Interior
Office of Indian Affairs Pine Ridge, S D , Window Rock Ariz , Ignacio, Calif , and Fort Wingate N M
Office of Education
Bureau of Mines
United States Department of Commerce
Bureau of the Census
Accident Prevention Conference
United States Treasury Department
Bureau of the Public Health Service
Surgeon General
Library
Office of Health Education
Advisory Cancer Council
Division of Sanitary Reports and Statistics
National Institute of Health, Division of Zoology
United States Department of Agriculture
Cooperative Extension Work in Agriculture and Home Economics

The Director of the Bureau continues as a member of the General Advisory Committee on Maternal and Child Health and Crippled Children's Work Two meetings of the committee were held during 1938, at which the Bureau was represented

COOPERATION WITH LAY ORGANIZATIONS

National Congress of Parents and Teachers —There have been no new development in 1938 in the cooperative relationships with the National Congress of Parents and Teachers There is slow but steady progress toward more widespread adoption of the congress policy for the examination of children in physicians' own offices, such examinations to be paid for by parents where possible, otherwise to be done gratis and in a few instances paid for by local parent-teacher associations Such payment is usually made on the initiative of the parent-teacher association

The usual authorization was given by the Board of Trustees for the printing of examination blanks, one half to be paid for at cost by the National Congress of Parents and Teachers, the other half donated by HYGEIA, the Health Magazine

The Advisory Committee to the Summer Round-Up held its usual meeting in January for the consideration of business relating to the summer round-up, but there was nothing in that meeting worthy of special note

General Federation of Women's Clubs—A meeting of the Advisory Committee of the General Federation of Women's Clubs was held Jan 14, 1939 The clubs continue their work in the child welfare, syphilis education and cancer education programs The Director of the Bureau was made a member of a special subcommittee to consider further revision of the blanks previously developed for community health surveys by women's clubs, but no conclusion has been reached by the committee Since this study has attracted little or no attention among women's clubs, it is possible that it may be dropped from the program

A new president, Mrs Saidie Orr Dunbar of Portland, Ore, took office and appointed a new chairman for the division of public health of the federation, Mrs Margaret Wells Wood of the Illinois State Department of Health, Springfield The Director of the Bureau of Health Education has been reappointed as a member of the advisory committee

4-H Clubs (National Committee for Boys and Girls Club Work)—In the annual "Healthiest Boy and Healthiest Girl" contests for 1938, four boys and four girls were named instead of just one boy and one girl as has been the case in the past Director C W Warburton of the U S Department of Agriculture, Extension Division, has expressed a special interest in arranging contests so that more benefits will accrue to boys and girls who participate but do not win prizes

Joint Committee on Health Problems in Education—The year 1938 was marked by two significant developments with relation to the Joint Committee

(*a*) The announcement at the February meeting by Dr Thomas D Wood, chairman of the committee for twenty six years, of his intention to resign, followed by his actual resignation in July

(*b*) The appointment, immediately on Dr Wood's announcement, of a subcommittee to plan for the reorganization of the Joint Committee; these appointments were made by Dr Charles C Wilson, Hartford, Conn, vice chairman of the Joint Committee

Dr Wilson has functioned as acting chairman of the committee since Dr Wood's announcement of his resignation The subcommittee to plan for reorganization consists of Dr Thurman B Rice, Indianapolis, chairman; Miss Mary Murphy Elizabeth McCormick Memorial Fund, Chicago, Miss Anne Whitney, Newton, Mass , Supt Willis A Sutton, Atlanta and Dr W. W Bauer, Chicago

The deliberations of the committee resulted in agreement on a tentative set of simple principles under which the present Joint Committee will cease to function when these principles have been adopted and will be replaced by a new Joint Committee, smaller in number with more flexible organization and more likely to be responsive to changing needs of changing times

At the meeting of the Joint Committee at Cleveland in February 1939, the reorganization was completed, providing for a committee of ten members, five from the National Education Association and five from the American Medical Association Terms of these members are to be as follows initial terms respectively, one, two, three, four and five years, subsequent terms, five years each, maximum, two terms in succession A chairman, vice chairman and secretary-treasurer are to be elected annually by the committee from among its members using the Hare system of proportional representation The scope of the committee was defined and an operating code of broad and elastic principles was adopted The committee is to be strictly a Joint Committee of the two organizations excluding from its membership all other organizations, but the committee is to draw freely on other organizations for consultant and advisory subcommittees Consultants and advisers are to have no vote in the Joint Committee All actions of the committee must be adopted by a vote of four fifths, except mail votes, which must be unanimous There shall be no quorum at meetings unless there are seven members present of whom at least three shall be from one of the participating organizations

SYMPOSIUM ON HEALTH PROBLEMS IN EDUCATION

A second Symposium on Health Problems in Education under the sponsorship of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, together with the Section on Pediatrics, the Section on Preventive and Industrial Medicine and Public Health, the Section on Ophthalmology and the Section on Laryngology, Otology and Rhinology of the American Medical Association, was held in the City Health Building, Civic Center, San Francisco, June 14 This auditorium, seating 300 persons, was believed ample in size, but it was found necessary to turn away more than 300 teachers and physicians who wished to attend the symposium Another symposium has been arranged for the American Medical Association meeting at St Louis in May 1939

American Public Health Association—The Director of the Bureau continues to serve his five year term, of which two

years remain, as a section councilor of the Section on Health Education of the American Public Health Association.

The American Public Health Association at its Kansas City meeting adopted a resolution which has been published in THE JOURNAL (Nov. 5, 1938, p. 1775) and which did not endorse the so-called health insurance proposals of the plans of the National Health Conference held in Washington in July.

Other Cooperative Relationships. — The Director of the Bureau was appointed by the Executive Committee of the Board of Trustees to represent the American Medical Association on the Section Committee on Minimum Requirements for Plumbing and Standardization of Plumbing Equipment. This committee is sponsored by the American Society of Mechanical Engineers.

Other organizations with which regular cooperative relationships are being maintained include:

State and Territorial Health Authorities (guest representative at meetings).
United States Public Health Service (participation in health conferences on invitation).
United States Department of Commerce (accident prevention conference).
National Organization for Public Health Nursing (consultant).
Committee on Evaluation of School Broadcasts of Federal Communications Commission (Ohio State University).

COOPERATION WITH STATE AND COUNTY SOCIETIES

The Bureau continues as in the past its endeavors to function as a clearing-house for health information and ideas for county and state medical societies and to establish and further cordial relationships between the medical profession and other organizations working for similar purposes.

PERSONAL APPEARANCES

Addresses to assembled audiences by the Director in 1938 numbered ninety-nine and by the Assistant Director fifty-eight, a total of 157. This compares with 125 addresses in 1937. These appearances required 42,859 miles of travel by railroad, automobile and bus. Appearances were made in twenty states.

The number of invitations has steadily increased and it is always necessary to decline a considerable number because of schedule conflicts and for other reasons.

HYGEIA CLIPPING LOAN COLLECTIONS

The clipping loan service of HYGEIA material bound into folders and accompanied by an outline for a proposed speech increased remarkably in 1938, owing largely to the publication in THE JOURNAL of an article "When Doctors Address the Public," by Dr. Paul A. Teschner, March 12, 1938, p. 155B. The total number of loans in 1938 was 895, as compared with 375 in 1937 and 230 in 1936.

BUREAU PUBLICATIONS

The pamphlet publications of the Bureau were maintained as in past years by revising, dropping or adding, as the demand seemed to indicate. New Bureau publications numbered twelve; those revised numbered five.

The use of photographic covers on HYGEIA suggested to the Director of the Bureau that these cover plates could be put to further use by employing them as a basis for posters. These posters were developed with special reference to economy, attractiveness and usefulness in the classroom. Therefore they were printed on lightweight paper so that they could be sold and mailed at a price of 25 cents for eight, including postage.

Material for publication in THE JOURNAL and in HYGEIA has been prepared by the personnel of the Bureau as occasion has demanded.

REVISION OF THE PERIODIC HEALTH EXAMINATION MANUAL

Revision of the Manual of Suggestions for the Conduct of Periodic Examination of Apparently Healthy Persons was authorized by the Board of Trustees and is in progress.

EXHIBITS

The Bureau cooperated, as in former years, with the Bureau of Exhibits in the preparation of exhibit material for use on various occasions, the principal ones being the Golden Gate International Exposition and the New York World's Fair.

Summary

The Bureau handled 5,474 communications from doctors, medical societies and cooperating agencies, 8,220 inquiries from the lay public and 1,145 pieces of radio audience mail. The Bureau broadcast thirty-seven dramatized radio programs in cooperation with the National Broadcasting Company. The radio library furnished scripts to 128 county medical societies and twenty-one state medical associations, distributing a total of 5,540 scripts covering 876 titles. Special radio broadcasts were arranged in connection with the annual session at San Francisco and the special session of the House of Delegates at Chicago. The Bureau cooperated with the Committee for the Protection of Medical Research and distributed 5,430 copies of pamphlets on protection of medical research to senior medical students; these were accompanied by an equal number of pamphlets on medical economics. Cooperation was given to five major departments of the United States government. The Bureau represented the American Medical Association in cooperative projects with the National Congress of Parents and Teachers, the General Federation of Women's Clubs, the National Committee for Boys and Girls 4-H Club Work, the National Education Association, the American Public Health Association, State and Territorial Health Authorities, National Organization for Public Health Nursing and the Federal Communications Commission's Committee on Evaluation of School Broadcasts. Public addresses were given to 157 audiences in twenty states, requiring 42,859 miles of travel; these audiences numbered 45,786 persons. Clipping loan collections from Hygeia were furnished to 895 doctors in forty-six states to aid them in preparing addresses for the public. The Bureau issued twelve new pamphlets and revised five old pamphlets. Eighty-two items were contributed to The Journal and thirty-four to Hygeia. Revision of the periodic health examination blank and manual was begun. The Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association was completely reorganized.

Bureau of Medical Economics

A number of phases of medical economics were under consideration during 1938. The study of medical care proceeded throughout the year; reports of the National Health Survey and the text of the National Health Program have been analyzed; assistance has been given to medical societies on the study and preparation of medical service plans; group hospitalization plans have continued to demand study and criticism; data have been assembled for the study of fee schedules, and other subjects such as collection of medical fees, sickness financing, malpractice insurance, workmen's compensation, relations between physicians and hospitals, the preparation and revision of publications of the Bureau and field engagements have consumed the time of the Bureau personnel.

STUDY OF MEDICAL CARE

In compliance with the resolution adopted by the Board of Trustees in December 1937 calling for a study of the need and supply of medical care and in accordance with the suggestions of the Committee on the Study of Medical Care, the Bureau of Medical Economics prepared nine forms to be used by county and state medical societies in the collection of data for such a study of medical care. Two information booklets containing suggestions on the conduct of the study and a special Summary Sheet were also prepared to make possible the collection of somewhat uniform information by the committees appointed by county medical societies to conduct the study. Also a special form was prepared for the use of state medical societies in the collection of information concerning statewide medical facilities. In all, the Study of Medical Care necessitated the preparation and distribution of 280,000 pieces of material.

The Committee on the Study of Medical Care recommended a special study of free services rendered by physicians and dentists throughout the United States. Records of free medical

services were prepared to be kept for one week by physicians and by dentists during each of three periods selected to obtain a representative sample of the services rendered during a year. For the conduct of this special study, 496,000 records were distributed to physicians and dentists.

As of Feb. 28, 1939, 416 county medical societies in thirty-six states have completed the Study of Medical Care in their counties and returned to the Bureau of Medical Economics the Summary Sheets with information obtained in the study. Many of the committees in charge of county studies returned detailed reports based on the findings of the study and including recommendations for the improvements that seemed necessary. In six states the returns are complete for all the counties in the state. Four state medical societies have also returned the special form which contains information regarding statewide arrangements for medical services.

Medical societies in forty-five states and the District of Columbia are participating in the Study of Medical Care, and it is expected that an additional number of medical societies will complete the Study of Medical Care at a later date.

Only two of the three periods to be included in the special study of free medical services have been completed, but as of Feb. 28, 1939, 434 counties have returned approximately 8,000 forms which represent the actual records of free medical services rendered by physicians and dentists. These records are being prepared for machine tabulation on punch cards, and more than 5,000 have been checked and are ready for tabulation. Twelve of the county and state reports have been published in the Organization Section of THE JOURNAL to indicate the nature of the information received and to encourage committees in charge of the Study of Medical Care to prepare complete reports.

MEDICAL SERVICE PLANS

During the past year there has been a noticeable increase in the activities of county and state medical societies in the study and development of medical service plans. The impetus for these activities may have come partly from the distaste on the part of the medical profession to a form of medical practice organized and operated by some nonprofessional agency, either voluntary or governmental, and partly from the encouragement given by the House of Delegates to medical societies to develop for local communities supplementary arrangements for the distribution of medical services according to local requirements and conditions.

The House of Delegates in 1934 established ten principles to assist medical societies in the organization of arrangements to supplement the private practice of medicine. The Study of Medical Care has developed data that in some instances have also brought to the attention of the organized medical profession problems in the distribution of medical services that deserve careful sympathetic consideration. These and other factors, not the least of which is the National Health Program, have focused the attention of both the medical profession and the public on "plans" to facilitate the distribution of medical care.

Interest in Medical Care Plans.—Since the Special Session of the House of Delegates in September 1938 some forty or more medical societies have sought assistance in the study and development of forms of medical service suited to their respective localities.

The growing interest of medical societies and of the public in special arrangements for organizing payments for medical services can be almost directly measured by the increasing number of experiments conducted by state and county medical societies. In 1934, 150 plans for the distribution of medical services were being conducted by medical societies in various communities in the United States. By 1935 this number had grown to 200, by 1936 to 250, by 1937 to 350, and at present the number is in excess of 450.

The existence of these organizational plans for the delivery of medical services is a direct refutation of the assertions that have been made concerning the unwillingness of the medical profession to tolerate change in the arrangements for payment for medical services. As a matter of fact, medical societies throughout the United States have in operation more experiments with new plans for the distribution of medical services than all the proponents of group payment plans have ever proposed.

Prepayment Plans.—The prepayment or group payment medical service plans that have received consideration from medical societies vary extensively in details but can be classified into two main types:

First, medical service plans on a unit service basis whereby an organization is created to collect funds from members and to provide medical services through participating physicians who agree to accept a prorated division of whatever funds are available after expenses have been paid.

Second, medical service plans on a cash indemnity basis, whereby an organization is created to collect funds from members and to pay a designated amount of cash to assist members in meeting their medical bills.

Under the unit service plan a schedule of the number of units to allow for each service is established, and the value of the unit is determined by dividing the amount of money available for medical bills by the number of units of service rendered. Under the cash indemnity plan, benefits are paid according to a listing of benefits which limits the amount that can be paid to the member or on assignment to his physician—the payments do not fix the physician's fees but assist the member to meet his medical bills.

Most of the proposals have contemplated the organization of some unit service plan. The simplicity of this type of arrangement, which entitles members to all necessary medical services with the participating physicians agreeing to divide the funds collected on an equitable basis is most appealing. There has been much experience with this unit system method, most of which would seem to indicate that there are difficulties which must be overcome before satisfactory results can be expected. Probably because of the known difficulties with unit service plans, the House of Delegates, both at the last annual session in San Francisco and at the recent Special Session in Chicago, gave particular encouragement to the development of cash indemnity plans.

A supplementary report, "Organized Payments for Medical Services," which describes practically all the various methods of organizing payments for medical services, contains a detailed discussion of the advantages and disadvantages of cash indemnity and unit service plans. The experience that will be gained under each of these two types of prepayment medical service plans may point the way to future arrangements for medical practice.

GROUP HOSPITALIZATION

Group hospitalization plans have continued to develop rapidly throughout the year 1938. Today there are eighty such plans in operation, with more than two and a half million members enrolled. Proposals for the organization of these plans are also receiving consideration in at least fifty-six communities.

The medical profession has given close attention to the development of group hospitalization plans beginning with the inauguration of the original plan. The first study of these plans was conducted by the Bureau of Medical Economics in 1932, and the criticisms and suggestions outlined in that study and in subsequent studies laid down many of the principles which the actual operation of group hospitalization plans has proved to be of fundamental importance. The consideration that the House of Delegates has given to the progress of group hospitalization plans has been based on sympathetic understanding of the desirability of some method of insurance payment to assist persons to pay hospital bills. At the same time the House of Delegates has evidenced concern over the possible deleterious effect on the practice of medicine in hospitals by an organized method of payment for hospital bills which would result in a lowering of the quality of services rendered to patients or a prostitution of the medical specialties practiced in hospitals.

It is a matter for concern on the part of the medical profession, in connection with these hospital service or group hospital insurance plans, that the inclusion of medical services in the hospital service contracts is being proposed. This feature of group hospitalization contracts has received the serious consideration of the House of Delegates on previous occasions and prompted the preparation of an extensive report, "Group Hospitalization," by the Bureau of Medical Economics, in which the experience of hospital service plans throughout the United States was analyzed. This report pointed out the undesirable effect on medical practice in hospitals when special medical

services such as anesthetic, pathologic and radiologic services are included in a hospital service contract on a service basis.

Policy Established by House of Delegates.—The attitude that has been taken by the House of Delegates toward the inclusion of medical services in group hospitalization contracts can be outlined as follows:

In June 1937 the House of Delegates recommended:

> . . . that the contract benefits provided by group hospitalization insurance should be limited to the room, bed, board and nursing facilities ordinarily provided by hospitals and routine medicines. . . . In regard to certain benefits offered by many hospital insurance plans, combining professional and technical services, the committee is in complete sympathy with those who would make every possible provision to prevent inclusion of any and all types of services involving medical care.

Also in 1937 the House of Delegates adopted the Ten Principles for the guidance of group hospitalization plans which are published on page 247 of the report "Group Hospitalization." The fourth of these Ten Principles states that the provisions in a hospital service contract should be limited exclusively to hospital facilities, which are defined to include "only hospital room accommodations, such as bed, board, operating room, medicines, surgical dressings, and general nursing care."

At the session of the House of Delegates in San Francisco (1938) the fourth of these Ten Principles was extended by the following statement:

> If for any reason it is found desirable or necessary to include special medical services such as anesthesia, radiology, pathology or medical services provided by outpatient departments, these services may be included only on the condition that specified cash payments be made by the hospitalization organization directly to subscribers for the cost of such services.

At the Special Session of the House of Delegates in September 1938 approval was given to the principle of hospital service insurance, provided these plans confine themselves to provision of hospital facilities and do not include any type of medical care.

The House of Delegates has declared that most of the difficulties concerning medical services in group hospitalization contracts can be avoided either by omitting all provisions for medical services on a service basis or by providing cash benefits directly to the subscriber for designated medical services. The first of these arrangements has been put into effect in cities such as St. Louis, Washington, D. C., and Wilmington, Del., where the group hospitalization plans exclude practically all such medical services. The second arrangement has been put into effect in Oakland, Calif., in Pittsburgh and Philadelphia, and in other localities, where the hospital service plans include certain medical services but on a basis which permits the payment of cash benefits directly to the patient or the physician. Such group hospitalization plans have the cooperation of the medical societies in these localities.

The recommendations of the House of Delegates have been concurred in by the action of state and county medical societies and by resolutions adopted by national societies of specialists, all of which have pointed out the undesirability of including special medical services in hospital service contracts on a service basis. It can be accepted, therefore, that the conviction of the medical profession generally is that the inclusion of medical services in a group hospitalization contract on a service basis will have an undesirable effect on the practice of medical specialties in hospitals and on the quality of the service rendered.

Hospitalization Contracts Show Variations.—An analysis of the contracts sold by sixty-three of the group hospitalization plans now in operation indicates that twenty-seven do not include x-ray services, thirty-one do not include pathologic services except for limited routine laboratory examination, and twenty-five do not include anesthesia. A comparison of the membership and financial experience of the plans that sell contracts in accordance with the recommendations of the House of Delegates indicates that a hospital service plan can enroll as many members and operate as successfully as the plans which include special medical services.

Whatever may be the attitude of hospital administrators or physicians concerning the arrangements that should exist between hospitals and physicians practicing in hospitals, it seems that this larger problem should not be confused with the principles that have been established concerning the inclusion of medical services in group hospitalization contracts to be sold by hospital service corporations. These principles specify that special medical services such as anesthetic, pathologic and radiologic services should not be included as benefits in a hospital service contract unless cash payments for these services are made to the subscriber or on assignment to his physician.

A contractual arrangement between the hospital and a hospital service corporation whereby a specified payment is to be made by the corporation to the hospital for each patient day of service, including professional services that are properly performed by physicians, raises many ethical and legal problems. Hospital administrators and physicians are justified in attempting earnestly to prevent the growth of these problems. While a hospital service corporation may contract with hospitals for the use of hospital facilities, it is believed to be undesirable for these corporations to contract with hospitals for the medical services in the hospital.

Practical Application of Principles.—The principles which have been adopted by the House of Delegates of the American Medical Association offer two possible alternatives:

First, that special medical service benefits be entirely omitted by restricting the benefits of the hospital contract exclusively to hospital facilities such as bed and board, use of the operating room, medicines, surgical dressings and general nursing care.

Second, that special medical service benefits may be included in the hospital service contract providing the benefits for such services are payable in cash to the subscriber or on assignment to his physician or hospital.

Both of these alternatives have been put into operation in various localities and either one will permit the organization of a hospital service plan that can have the full support of the medical profession.

At the same time the Committee on Hospital Service and the Council on Hospital Insurance of the American Hospital Association seem to be encouraging the development of plans that include special medical services on a service basis. It appears that the staffs of local hospitals are first induced to support a proposed hospital service plan which includes special medical services on a service basis and afterward an attempt may be made to secure approval of the plan by the local county medical society. The county medical society is then faced with the problem either of disavowing the principles suggested by the American Medical Association and by the state medical society or of disapproving the action taken by members of the hospital staffs. The American Hospital Association at its last annual session approved the extension of hospital care insurance plans to include medical fees in hospital practice when the arrangements are approved by the local county medical society. At a recent conference between representatives of the American Medical Association and the American Hospital Association this problem was frankly discussed.

The recommendation of the House of Delegates with regard to the principle that special medical services on a service basis be entirely excluded from the hospital service contract, or that direct cash benefits be paid for such services, has received official sanction by a considerable number of medical societies. There is need, however, for a more thorough understanding of this recommendation by many physicians, hospital administrators and the public.

This principle takes on added importance in view of the suggestions being made by directors of hospital service corporations that the hospital service contract be extended to include all medical services in the hospital—surgical and general medical services as well as the special medical services of anesthesia, pathology and radiology. The development of medical service plans under the auspices of medical societies or voluntary organizations reemphasizes the necessity for maintaining separate provisions for the physician's services and for hospital facilities.

A joint report of the three national hospital associations has suggested that federal legislation be sought to permit the licensing of hospital service corporations similar to the federal licensing of credit unions. It is contemplated that such federally licensed hospital service corporations would be the proper agencies to enter into contracts with the government for the care of the indigent sick. This proposal also emphasizes the necessity for separate arrangements for the provision of the personal services of physicians.

Apart from the specific principles for group hospitalization plans, the House of Delegates in 1935 adopted the following:

The House of Delegates would again emphasize particularly the necessity for separate provisions for hospital facilities and the physician's services. Payment for medical service, whether by prepayment plans, instalment purchase or so-called voluntary hospital insurance plans, must hold, as absolutely distinct, remuneration for hospital care on the one hand and the individual, personal, scientific ministrations of the physician on the other.

RELATIONS BETWEEN PHYSICIANS AND HOSPITALS

The relations of physicians and hospitals concerning medical services for hospitalized patients have been brought to a sharp focus by the development of group hospitalization plans, all-inclusive rate plans and governmental arrangements for hospital care of the indigent which look to the hospital as the source of medical care and tend to subordinate the physician to a status similar to that of an employee of the hospital.

It is suggested that the House of Delegates and state and county medical societies might properly take cognizance of the fact that certain types of group hospitalization plans and other payment arrangements for hospital care may tend to establish relations between physicians and hospitals that are not desirable for the welfare of hospitalized patients or for the furtherance of good medical practice in hospitals.

At the last annual session the House of Delegates recommended that a joint study be made by the Council on Medical Education and Hospitals and the Bureau of Medical Economics to determine the existing relations between hospitals and the physicians practicing therein. This study was to be undertaken with a view toward a clearer definition of the relationships in the departments of anesthesia, radiology, pathology and physical therapy in order that ethical standards may be established for the practice of medicine by physicians in hospitals which would prevent the exploitation of either the public, the hospitals or the physicians.

The results of this study will be reported by the Council on Medical Education and Hospitals. As a part of the study, the Bureau of Medical Economics has made an analysis of schedules obtained from 876 radiologists by the Inter-Society Committee for Radiology concerning the economics of the practice of radiology.

MEDICAL FEE SCHEDULES

The Bureau of Medical Economics, since it was established in 1931, has made an effort to collect fee schedules from county medical societies. During 1934 the Bureau computed minimum and maximum average fees for the United States for 530 items from 384 county schedules which it had in the files at that time. This list of 530 items with average fees was kept in the files of the Bureau where it could be referred to on questions involving medical fees, but at no time has any fee schedule been recommended for adoption by county medical societies.

In November 1937 a concentrated effort was made to secure a more complete and up-to-date record of county fee schedules. A letter was sent to the secretary of every county medical society in the United States requesting a copy of the fee schedule that had been adopted or was being used by the county society at that time. A complete list of the number of letters sent out and of the number of replies and schedules returned by the county society is given in table 1.

At the annual meeting of the House of Delegates of the American Medical Association in San Francisco in June 1938 the following Resolution on Fee Schedules was adopted:

Whereas, State and county medical societies have from time to time, on their own initiative or at the request of others claiming a valid or social interest in the cost of medical services to a particular group, established so-called fee bills on which the contracting persons or groups agree to base charges; and

Whereas, Such fee bills often set up without due regard to the equitable interest of the various groups concerned furnish an implement through which exploitation is practiced and abuses encouraged; and

Whereas, The necessity for or advisability of such schedules has never been considered by the House; and

Whereas, Controversy over the application of such schedules is rife, serving to divert the attention of the contracting persons from the central fact—namely, the quality of medical care—thus reflecting unfavorably on the profession and lending comfort to those critics who charge it with the adoption of trade union methods; and

Whereas, It has been the unwritten rule, established by a long line of ethical practitioners, both past and present, to adapt charges for medical services to the ability of his patient to pay, untrammeled by fixed community schedules; therefore be it

Resolved, That this device, appearing with increasing frequency, examined by an appropriate agency of the American Medical Associa to the end that the Association may declare itself on certain controver points, among which are:

(*a*) The advisability of or necessity for fee schedules in the pu interest.

(*b*) Their ethical or unethical qualities.

(*c*) Necessity for certain fixed principles to guide constituent units the Association when and if it is deemed, in the public interest, necess to adopt such a device, and

(*d*) Whether such schedules, approved by constituent units of Association, should or should not provide for elasticity so as to per of adaptation to wage levels, specialized medical services, variati based on differential costs as between urban, semiurban and rural prac and other related considerations.

In June 1938 the Bureau began compiling and tabulating t figures recorded on the county medical societies' fee schedul At first it was necessary to make a composite list of ite included in the 558 county fee schedules. The nomenclature a classifications in the schedules varied greatly. No two sched-ules were completely alike. Considerable time and work were involved in making a complete list that would include the services on which three or more counties reported fees. Many of the counties reported a very short schedule—a list of the most common services performed by the general practitioner in his daily practice. Others had a very elaborate and detailed list of more than 300 items including many unusual and seldom

Total for United States	2,021 100%	559 28%	228 11%	1,234 61%

used tests and operations. In the final list, which includes a total of 606 items, the medical and surgical services are subdivided under ten main headings and twenty-three subheadings. All of the fees have now been trasferred from the county schedules to this uniform list of items and the number of fees reported for each item has been computed.

Table 2 gives a list of the medical and surgical services on which the greatest number of societies reported a fee. This list indicates the type of services on which the majority of the

county medical societies considered established fees to be practicable. Except for surgical procedures, complement fixation tests for syphilis and postmortem examinations, the list includes only services which the general practitioner might be expected to perform every day under ordinary conditions. The fact that so many county medical societies' schedules do not include

TABLE 2.—*Common Services for Which More That 100 Counties Reported Fees*

established fees for the remaining 581 items, which make up the composite list, indicates the difficulty of establishing fees for services for which the amount of time, skill and responsibility required cannot be determined in advance.

Study of Medical Fees to Continue.—The next phase of study, now in progress, is to compile average minimum and maximum fees for each state for every item on which a sufficient number of fees from which to compute an average are reported. Average minimum and maximum fees for the United States will be computed for all the 606 items. These average fees will be used as a basis for a further study on the question of the necessity or desirability of established fee schedules for medical and surgical services. There are many other factors which must be considered in presenting the arguments for and against this question, but to enter into a discussion of fee schedules it is necessary to know the existing average fees in the various states and the geographic and political divisions of the United States. An equitable fee depends not only on the professional skill required and the time consumed but also on costs of living and the economic status of the majority of the people in a given locality. Medical fees also show considerable variation in rural areas as compared to industrial centers. Consequently, average fees for the entire United States would be useful to any particular county society only as a comparison of the difference between the local medical fees and the average fees for the United States. Average fees for a state might be a more practical guide for a county medical society within the particular state if the average fees were derived from figures that are representative of the actual amounts usually charged for medical services in that state.

These average figures will also be useful as a guide in determining equitable fees for medical services under various medical care plans for special economic groups such as the indigent, Farm Security Administration clients and the low income group. At the present time requests have come from more than twenty-five county medical societies that do not have fee schedules or wish to revise their fee schedules for a schedule of average fees which could be used as a guide in setting up or revising a fee schedule.

The completed study of fee schedules, so far as information is available, will be submitted as a supplementary report of this Bureau.

COLLECTING MEDICAL FEES

The Bureau of Medical Economics continues to receive complaints from physicians concerning the practices of commercial collection agencies in the collection of medical accounts. A report "Collecting Medical Fees" which was published serially in THE JOURNAL beginning in May 1938 outlined and discussed the various systems used by commercial collection agencies with particular emphasis on practices that tend to defraud the unwary physician and often deal harshly with his patients. A special study of professional credit and collection bureaus was also included in this report.

During the past year 460 copies of the report "Collecting Medical Fees" were distributed to medical societies, physicians, collection agencies, libraries and lay individuals. Including a previous report on collecting medical fees, a total of 6,200 reports have been distributed within the past six years to assist physicians with their collection problems.

One of the most significant developments in medical economics during recent years has been the organization of credit and collection bureaus by county medical societies or by groups of physicians. This movement toward professional control of agencies for the collection of medical accounts has progressed rapidly during the past five years and symbolizes the effort on the part of physicians to eliminate many of the undesirable features that have arisen because of dissatisfaction with methods used by commercial collection agencies and because of the need for an agency to organize some of the "business" aspects of medical practice.

According to available records there are at least fifty professionally controlled credit and collection bureaus in operation, and twenty-five others are proposed. Reported experiences with the operation of these bureaus indicates that they perform a valuable service for the patients and the physicians in the communities where they were organized.

Inappropriate Collection Methods.—Improper or unsatisfactory collection arrangements are prominent among the reasons which cause medical accounts to have the highest ratio of bad debts of all retail accounts in the United States. The consequent loss of payments amounts to an estimated one-fourth billion dollars annually. An even greater damage to the physician's practice is caused by improper credit and collection practices that lead to dissatisfaction with the use of the sliding scale of fees and sometimes may encourage malpractice suits. Greater attention to the "business" side of medical practice with special regard for extension of credit to patients and billing procedures is not unprofessional or beneath the dignity of the medical profession, particularly when it can be shown that lack of attention to the proper conduct of the business side of medicine results in extensive harm to the delivery of good medical service by threatening to destroy the personal and friendly relations between physicians and their patients.

Familiarity with Collection Methods Essential.—Once again physicians should be urged to familiarize themselves with the proper procedures to follow in the use of a third party agency to collect medical accounts. While complaints continue to be received, there has been an encouraging decrease in the number of complaints from physicians who have been defrauded by unscrupulous collection agencies and methods. Recently the postal authorities convicted the officers of a large collection agency of fraud and it appears that other collection agencies utilizing similar contracts will no longer be allowed to use the mails to transact their business. Legislation in certain states for the licensing of collection agencies is contemplated in the hope of providing at least some regulation of these agencies. The most hopeful possibility, however, is that the individual physician will learn to avoid collection agencies that use methods which almost invariably lead to unfair dealings with his patients and sly handling of his accounts.

SICKNESS FINANCING COMPANIES

The formation of special financing organizations which offer to make available funds with which to finance medical accounts is creating an important financial institution which may introduce new problems in the medical field. In the past, medical societies and physicians have not been in favor of finance plans on the ground that such arrangements do not lower the cost of medical care but instead result in an additional cost to the patient and in many of the arrangements increase costs for the physicians. It has been felt that persons with low incomes whose medical accounts require special arrangements are deserving of a reduction rather than an increase in charges by the addition of interest or other expenses paid to a financing agency.

It is true that patients now have access to a variety of lending agencies such as personal finance companies, Morris Plan and industrial banks, personal loan departments of banks, credit unions, remedial loan societies, pawnbrokers and unlicensed lenders of all types. For example, it was estimated that in 1936 more than $40,000,000 was lent by personal finance companies alone to patients for medical, dental and hospital bills.

The feasibility of developing special finance plans, perhaps under the auspices of medical societies or groups of physicians, will undoubtedly be given wide consideration. Already several medical societies have experimented with a special financing arrangement. The Bureau of Medical Economics has records of forty-five sickness financing plans the majority of which are still privately financed and owned institutions. A thorough study of sickness financing arrangements would seem to be warranted, especially in view of the likelihood of a development of financing arrangements under sponsorship of medical societies.

MALPRACTICE INSURANCE

Within the past few years, considerable changes in policies and rates for malpractice insurance have been made by practically all companies writing this type of insurance. Increasing underwriting losses have caused insurance companies to become concerned over the selection of "malpractice risks." The present unsettled situation in the underwriting of malpractice insurance is due to many possible causes, among which are the increasing complexity of medical practice involving more general use of special apparatus such as x-ray and physical therapy, a resentment on the part of certain patients of efforts of physicians to collect payments for delinquent accounts, critical comments by some physicians and the general attempts which have recently been made to discredit the medical profession. These and other factors have led to an increasing tendency for patients to allege that their physicians are guilty of malpractice.

A question has been raised as to whether there is any relationship between the American Medical Association and insurance companies writing malpractice insurance, apparently because several companies require that an applicant be a member of a medical society. These insurance companies establish their own policies, which, presumably, change with experience. The American Medical Association has not attempted to influence insurance companies in the formulation of their policies pertaining to rates, coverage, type of risks accepted, or any other part of the companies' business.

The Bureau of Medical Economics has made an effort to secure from the companies a statement of their policies in order that intelligent replies might be made to correspondents who inquire about malpractice coverage.

PUBLICATIONS

In addition to the reports already mentioned, two new studies have been published, "Medical Relations Under Workmen's Compensation—Developments since 1930" and "Health Insurance in England," which bring down to date the information in these two important fields of medical economics. The report "Sickness Insurance Not the Remedy" has been rewritten with much additional information, and the report on "Contract Practice" has been revised with new material added that involved a study of nearly a thousand of such plans for which records exist in the Bureau. Other publications that were reprinted during the year were "Critical Analysis of Sickness Insurance," "The Economics and Ethics of Medicine" and "Sickness Insurance Catechism."

Developments and extensions in the medical program of the Farm Security Administration have required examination and analysis of the different arrangements made by the Farm Security Administration with state and county medical societies. Many medical societies, before entering into such agreements, have asked for information, suggestions and copies of the plans used in other states. A full report of the Farm Security Administration plans is included as a chapter in the report "Organized Payment for Medical Services." Likewise medical societies have requested detailed information concerning plans for the care of the indigent. A chapter describing the arrangements for the care of the indigent throughout the United States is also embodied in the report "Organized Payments for Medical Services." A chapter in this report also outlines the developments under the Social Security Act which are of interest to medical societies.

Medical economics abstracts were prepared each week for the Organization Section of THE JOURNAL. In many cases these abstracts require considerable research and statistical work or translation from European publications. Articles on socialized medicine and other subjects in medical economics were also prepared for several nonmedical magazines.

NATIONAL HEALTH PROGRAM

The factual data on which the National Health Program was based were taken largely from the information collected in the National Health Survey. As soon as the reports of the National Health Survey became available, the Bureau prepared analyses of certain parts on which comments could be made without consulting all the basic data.

Likewise, as soon as the text of the National Health Program was issued, an analysis was made for the Board of Trustees and for use of the reference committees of the Special Session of the House of Delegates in September 1938.

These analyses and additional statements bearing on particular portions of the National Health Program were made available to the committee of the House of Delegates which met with government representatives in October and December 1938 to discuss the recommendations of the National Health Program.

DEPARTMENT OF JUSTICE INVESTIGATION

When the Department of Justice investigator visited the Bureau, every assistance was given him to examine all the source files and correspondence bearing on the mission for which he was sent. This assistance went further than the mere compliance with requests to see specific material. Suggestions were made concerning other material which it was thought might be of interest or assistance. All reprints and publications of the Bureau were given to the investigator and he was invited to return at any time, when every possible assistance to examine every document in the Bureau files would be given him. The contact with the investigator was very cordial.

Later, when the subpenas were received for specific material, much time was required to collect from the Bureau files all the material needed to comply with the subpenas. Photostatic copies of the original material sent to the Department of Justice, Washington, D. C., are on file in the Bureau.

OTHER ACTIVITIES

One important portion of the work of the Bureau is the furnishing of information on medical economics subjects which comprise fifty-five main subject classifications with 159 subclassifications. Requests for information on these topics come to the Bureau by letter, telephone, telegram or personal visits from physicians, both as individuals and as officers of medical organizations, from individual lay persons and from administrators of various agencies.

The majority of the written requests have to be answered on an individual basis, which requires considerable research and library work to secure the specific information requested. This is particularly true of requests received from secretaries of committees appointed by medical societies to conduct special studies in various problems of medical economics. Requests are chiefly for information concerning group hospitalization, medical care plans, state medicine, contract practice plans, collection agencies, insurance companies (particularly malpractice insurance), costs of medical care and medical education, income from medical practice, distribution of physicians and hospitals, rural medical services, care of the indigent sick, and medical relations under workmen's compensation.

Representatives from a variety of organizations, but chiefly from state and county medical societies, often visit the Bureau in person for consultation on particular medical economic problems. These consultations have served a distinctly useful purpose in acquainting representatives of the county medical societies with the functions of the Bureau and in making known to representatives of lay organizations that the source files of the Bureau contain much information concerning the medical economic problems in which they are interested, as well as to acquaint the Bureau with the nature of their problems. In a

number of instances the visits from interested persons have developed into valuable contacts with important organizations in other fields, such as public welfare, insurance, foundations, government agencies, workmen's compensation commissions and industry.

On many occasions the Director or his associates are invited to address or confer with state or county medical societies, national organizations such as the American Association of Medical Students, American Hospital Association, American Pharmaceutical Association, American Public Welfare Association, National Association of Retail Druggists, National Conference of Social Workers, National Education Association, United States Children's Bureau, United States Public Health Service, Conference on Rural Medical Care, State and Provincial Health Authorities of North America and local groups such as women's auxiliaries, state hospital associations, women's clubs, public forums, high school clubs, colleges and universities, Y. M. C. A., Rotary, Kiwanis, and Lions clubs, and consumer groups. Engagements with these medical societies and national or local organizations have averaged one a week during the year.

Summary

Study of Medical Care.—Medical societies in forty-five states and the District of Columbia are participating in the Study of Medical Care. Already 416 county medical societies in thirty-six states with the cooperation of other agencies and organizations interested in medical services have completed a study of the need and supply of medical care in their communities.

A special study of free medical services rendered by physicians and dentists throughout the United States has been made by having records of free medical services kept for three representative periods of seven days each.

A supplementary report will summarize the results of the Study of Medical Care and the special study of free medical services.

Medical Service Plans.—Medical societies throughout the country have taken a very active part in the study and development of medical service plans. A supplementary report, "Organized Payments for Medical Services," has been prepared which describes practically all the various methods of organizing payments for medical services.

The prepayment or group payment medical service plans which have received consideration from medical societies can be classified into two main types: (1) unit service plans, which provide medical services through participating physicians who agree to accept a prorated division of whatever funds are available after administrative and other expenses are paid; (2) cash indemnity plans, which provide a designated amount of cash to assist members in meeting their medical bills. Experience gained under each of these types of medical service plans will, no doubt, produce much helpful information.

Group Hospitalization. — Hospital insurance plans organized by hospital administrators and physicians have continued to receive widespread attention. One major problem in connection with these plans is concerned with the question of including or excluding special medical services, such as anesthesia, pathology and radiology. The experience gained in the operation of these plans emphasized the importance of the recommendations of the House of Delegates that such special medical services be omitted from a hospital service contract or included only on the basis that cash benefits be payable directly to the member.

The development of medical service plans raises a further question as to the relation between hospital service plans and other medical services in the hospital —surgical and general medical services. The consensus seems to be that a medical service plan should be kept separate in its organization and administration from a hospital service plan.

Relations Between Physicians and Hospitals.—Various organized arrangements for the payment of medical services in hospitals brought into sharp focus the necessity for establishing a clearer understanding of relationships between the hospital departments of anesthesia, radiology, pathology and physical therapy and physicians practicing in these departments.

Medical Fee Schedules. — An exhaustive survey of county medical society fee schedules has been completed. All the county fee schedules that could be obtained were classified and tabulated into a composite fee table, which includes a total of 606 items and the "average" minimum and maximum fees for each item.

A supplementary report, "Medical Fee Schedules," has been completed in accordance with the request of the House of Delegates that a study be made of the advisability and necessity of fee schedules.

Collecting Medical Fees.—A significant development in medical economics during recent years has been the organization of credit and collection bureaus by county medical societies or by groups of physicians. The movement toward professional control of agencies for the collection of medical accounts has been reported in a special study, "Collecting Medical Fees." This report also outlines and discusses the various systems used by commercial collection agencies and gives particular emphasis to the practices that tend to defraud the unwary physician. Physicians are urged to familiarize themselves with the preferable procedure to follow in the use of a third party agency to collect medical accounts.

Sickness Finance Companies. — Recently interest has been evinced in the development of special medical finance plans under the auspices of medical societies or groups of physicians. Patients now have access to a variety of lending agencies and careful study should be given to the development of financing arrangements under the sponsorship of medical societies.

Malpractice Insurance. — Policy provisions and rates for malpractice insurance have been subjected to considerable changes in the past few years. Increasing underwriting losses have caused insurance companies to become concerned over the selection of malpractice risks. The present unsettled situation in the underwriting of malpractice insurance is due to many causes, not the least of which has been the recent attempts to discredit the medical profession.

Publications.—In addition to the reports already mentioned, two new studies, "Medical Relations Under Workmen's Compensation — Developments since 1930" and "Health Insurance in England," were published. Two new reports, "Sickness Insurance Not the Remedy" and "Contract Practice," have been submitted for publication.

The new report "Organized Payments for Medical Services" will also contain chapters descriptive of Farm Security Administration plans, arrangements for the care of the indigent sick and medical care developments under the Social Security Act.

Articles and abstracts pertaining to medical economic problems were prepared for the Organization Section of The Journal and for some nonmedical magazines.

National Health Program. — Analysis and statements pertaining to the National Health Program and the National Health Survey were prepared for the Board of Trustees and the committee appointed by the House of Delegates to confer and consult with proper federal representatives.

Department of Justice Investigation.—Every possible assistance was given to the investigator from the Department of Justice to examine all the source files and correspondence of the Bureau which might have a bearing on the mission for which he was sent.

Other Activities.—Correspondence, consultations and speaking engagements increased continuously throughout the year but have made possible a wide distribution of information concerning medical economic problems.

Bureau of Investigation

Dr. Paul C. Barton, formerly a member of the administrative personnel of the Council on Pharmacy and Chemistry, assumed the duties of Director of the Bureau of Investigation Nov. 1, 1938.

The services of this Bureau continue to be utilized by physicians and laymen, and many inquiries are received from representatives of organizations that are concerned with the detection and exposure of fraud for the purpose of public protection, as well as from official agencies that are concerned not only with the detection and exposure of fraud but also with the prosecution of impostors. Approximately 10,000 direct inquiries were received by the Bureau in 1938, about 60 per cent of which came from the lay public and about 40 per cent from physicians. It seems to be evident that the Bureau is filling a real need in supplying information, since many inquirers, including busy physicians, take time to write letters of acknowledgment and thanks for the information furnished in response to their inquiries. An increasing number of communications requesting information are received from students and from the members of consumers' study groups. In most instances the material provided by the Bureau for students and for the members of study groups is utilized in the preparation of essays presented before classes, and thus wide distribution is given to the information that is made available through this Bureau.

Many requests for information are received from newspapers, magazines, broadcasting stations and advertising agencies concerning the acceptability of products for which advertising is offered. Most of these requests come from publications, radio station operators and advertising agencies in the Eastern part of the United States and in the Middle West.

The services of the Bureau of Investigation continue to be used by various agencies of the federal government and the utmost possible cooperation is maintained between the Bureau and the Food and Drug Administration, the Federal Trade Commission and the Post Office Department. These governmental agencies provide the Bureau with official releases based on fraud orders, notices of judgment and other orders, and much of the information so secured is published in THE JOURNAL. Cordial cooperative effort is maintained with Better Business Bureaus throughout the United States.

The Bureau has continued the long-established policy of providing physicians, teachers, health officers and civic groups with material to be used for exhibit purposes and for the preparation of public addresses. The amount of such material distributed during the year was approximately the same as in each of several preceding years.

Articles of current interest were prepared by the Bureau for publication in the Association's periodicals during the year, many of which were contributed by Dr. Arthur J. Cramp, who was for many years Director of the Bureau of Investigation.

Bureau of Exhibits

THE SCIENTIFIC EXHIBIT

There were 242 signed applications for space in the Scientific Exhibit at the San Francisco session, of which 161 were accepted, 66 per cent. The Scientific Exhibit occupied a floor area of 27,665 square feet, located in various halls, rooms and corridors of two floors. Because of the somewhat limited space available there was much congestion.

Total Exhibits, 1938.—In addition to 161 exhibits for which there were signed applications, there were two special exhibits on fractures and on anesthesia, and four motion picture booths sponsored by the various sections of the Scientific Assembly. There were 136 exhibits sponsored by the sections, forty-nine of which were accompanied by papers read before the various sections during the week.

Section exhibits	136
Educational group	
National organizations	16
Organized medicine	9
Motion picture booths	4
Special (subsidized) exhibits	2
	167

Exhibits and Registration.—For each exhibit in the Scientific Exhibit, thirty-six Fellows of the Association registered at the General Registration Booth. This was a slightly smaller ratio than last year, as shown in the table below, in spite of the fact that a larger percentage of applications were rejected this year than in former years. The lower figure this year, therefore, is without much significance.

	Total Exhibits	Total Registration	Attendance per Exhibit
Cleveland, 1934	167	6,293	37.7
Atlantic City, 1935	213	8,166	38.3
Kansas City, 1936	176	6,824	38.7
Atlantic City, 1937	254	9,764	38.4
San Francisco, 1938	167	6,034	36.0

Section Exhibits.—The fifteen sections of the Scientific Assembly presented 136 exhibits, an average of nine each, as compared with thirteen each last year. The largest number of exhibits presented by any section were in the Section on Pathology and Physiology with seventeen exhibits and the smallest number the Section on Laryngology, Otology and Rhinology with four exhibits. Following is a comparison of exhibits presented by the various sections for the past several years:

	Kansas City 1936	Atlantic City 1937	San Francisco 1938
Practice of Medicine	21	18	11
Surgery	17	26	16
Obstetrics and Gynecology	6	10	6
Ophthalmology	11	11	8
Laryngology, Otology and Rhinology	5	9	4
Pediatrics	11	9	6
Pharmacology and Therapeutics	7	9	9
Pathology and Physiology	11	17	17
Nervous and Mental Diseases	5	8	7
Dermatology and Syphilology	7	12	11
Preventive Medicine	6	14	5
Urology	7	8	6
Orthopedic Surgery	11	11	16
Gastro-Enterology	12	18	8
Radiology	10	14	6

The Section on Practice of Medicine was represented by Dr. Fred M. Smith, Iowa City, who was also secretary of the section. There were twenty-five applications presented, eleven of which were accepted and one transferred to another section. One exhibit received a Bronze Medal and one a Special Citation. Three of the exhibits were accompanied by papers read before the section.

The Section on Surgery, General and Abdominal, was represented in the Scientific Exhibit by Dr. Grover C. Penberthy, Detroit. There were thirty-two applications, of which sixteen were accepted. In addition to the exhibits, the section presented a motion picture program in an area adjoining the exhibits. Three exhibits received Certificates of Merit and two Honorable Mention. Five of the exhibits were accompanied by papers read before the section.

The Section on Obstetrics and Gynecology was represented by Dr. H. Close Hesseltine, Chicago. There were twelve applications, of which five were accepted and one was transferred from another section. In addition to the exhibits there was a motion picture program presented as a special feature in an area adjoining the exhibit space. One exhibit received Honorable Mention. Two exhibits were accompanied by papers read before the section.

The Section on Ophthalmology was represented by a committee composed of Dr. Georgiana Dvorak Theobald, Oak Park, Ill., chairman, Dr. Dohrmann K. Pischel, San Francisco, and Dr. Derrick Vail, Cincinnati. There were fourteen applications for space, of which eight were accepted. There were no awards made in this section. Five of the exhibits were accompanied by papers read before the section. A very successful motion picture program was run adjacent to the exhibits.

The Section on Laryngology, Otology and Rhinology was represented by Dr. Robert C. Martin, San Francisco. There were seven applications for space, three of which were transferred to other sections, leaving four exhibits to be accepted. One exhibit received an Honorable Mention. Two of the exhibits were accompanied by papers read before the section.

The Section on Pediatrics was represented by Dr. F. Thomas Mitchell, Memphis, Tenn. There were eight applications for space, of which six were accepted. There were no awards made in this section. One exhibit was accompanied by a paper read before the section.

The Section on Pharmacology and Therapeutics was represented by Dr. Wallace M. Yater, Washington, D. C. There were thirteen applications for space, of which nine were accepted. One exhibit received a Gold Medal and one a Certificate of Merit. Four exhibits were accompanied by papers read before the section.

The Section on Pathology and Physiology was represented by Dr. F. W. Konzelmann, Philadelphia. There were twenty-one applications for space, of which sixteen were accepted and one was transferred from another section. Two of the exhibits in this section were awarded medals. Three of the exhibits were accompanied by papers read before the section.

The Section on Nervous and Mental Diseases was represented by Dr. Roland P. Mackay, Chicago. In addition to the exhibits, a motion picture program was presented in an adjoining area. There were twelve applications for space, of which seven were accepted. None of the exhibits received awards. One exhibit was accompanied by a paper read before the section.

The Section on Dermatology and Syphilology was represented by Dr. Clark W. Finnerud, Chicago. There were eighteen applications for space, of which eleven were accepted. The section presented a Symposium on Industrial Dermatoses, which received a Special Citation. There were seven papers presented before the section by exhibitors.

The Section on Preventive and Industrial Medicine and Public Health was represented by Dr. Paul A. Davis, Akron, Ohio. The section had twelve applications for space, of which five were accepted. One of the exhibits received a Silver Medal and one exhibit was accompanied by a paper read before the section.

The Section on Urology was represented by Dr. R. S. Ferguson, New York. There were nine applications for space, of which six were accepted. One exhibit received a Certificate of Merit.

The Section on Orthopedic Surgery was represented by Dr. Norman T. Kirk, San Francisco. The section presented twenty-two applications for space, of which sixteen were accepted. The Committee on Awards presented to exhibits in this section one Silver Medal, two Certificates of Merit and one Honorable Mention. Four of the exhibits were accompanied by papers read before the section.

The Section on Gastro-Enterology and Proctology was represented by Dr. J. A. Bargen, Rochester, Minn. The section had fourteen applications for space, of which eight were accepted. One exhibit received a Certificate of Merit. Four exhibits were accompanied by papers read before the section.

The Section on Radiology was represented by Dr. E. E. Downs, Woodbury, N. J. There were eleven applications of which six were accepted. None of the exhibits received awards, but all six exhibits were accompanied by papers read before the section.

Motion Pictures.—Four sections presented motion picture programs in connection with the exhibits—the Section on Surgery, General and Abdominal, the Section on Obstetrics and Gynecology, the Section on Ophthalmology and the Section on Nervous and Mental Diseases. All the pictures shown were selected with considerable care by the section representatives, the pictures being previewed in some instances. Projectors and operators were furnished by the Association and the programs carried out under the control of the director of the Scientific Exhibit. For the most part the space available for these motion picture programs was too small and crowded, resulting in much congestion. All the pictures attracted large audiences.

Many motion pictures were shown in individual booths by the various exhibitors, who had included part of their evidence in the form of motion pictures. These pictures formed a serious problem in the narrow corridors where the Scientific Exhibit was located.

Special Exhibits.—The Special Exhibit on Fractures was carried on under the official direction of the committee composed of Dr. Kellogg Speed, Chicago, chairman, Dr. Frank D. Dickson, Kansas City, Mo., and Dr. Walter Estell Lee, Philadelphia. More than fifty physicians from various parts of the country assisted with the demonstrations, and a pamphlet describing the exhibit was distributed. Acknowledgment is made to Major General C. R. Reynolds, the Surgeon General, United States Army, Washington, D. C.; Colonel Roger Brooke, M.C., United States Army, Letterman General Hospital, San Francisco; Lieut. Colonel Norman T. Kirk, M.C., United States Army, Letterman General Hospital, San Francisco; Dr. C. H. Chandler, dean of Stanford University School of Medicine, San Francisco, and Mrs. Mitchell and Mrs. McMurray, nurses from the Stanford University Hospital, San Francisco, for the efficient service which they rendered in connection with the fracture exhibit. Appreciation is also expressed to Dr. Carleton Mathewson Jr., local representative in San Francisco for the fracture exhibit, for his excellent cooperation.

The Special Exhibit on Anesthesia was presented for the second time under the auspices of a committee composed of Dr. Ralph M. Waters, Madison, Wis., chairman; Dr. P. J. Hanzlik, San Francisco; Dr. Chauncey D. Leake, San Francisco, and Dr. Philip D. Woodbridge, Boston, assisted by a competent corps of demonstrators. There was a material increase in the exhibit this year over last year. A pamphlet describing the exhibit was distributed during the meeting, for which there has been a persistent call during the ensuing months. The pamphlet has been reprinted and is now available.

Committee on Awards.—The Committee on Awards was composed of Dr. Eben J. Carey, Milwaukee, chairman; Dr. H. C. Bumpus Jr., Pasadena, Calif.; Dr. Dean Lewis, Baltimore; Dr. E. E. Irons, Chicago, and Dr. W. Walter Wasson, Denver. The duties performed by this committee are of a most arduous nature, involving careful study of each separate exhibit and conscientious and qualified judgment of the merits and value of each.

ASSOCIATION EXHIBITS

The demand for exhibits for loan purposes from the headquarters of the Association has increased again this year. At the present time there are forty-two exhibits pertaining to the various departments of the Association or to subjects in which those departments are interested. During the year, exhibit material was sent out on 124 occasions to forty states. Very often two or more exhibits went to one place, greatly increasing the number of items lent.

There were no international expositions or world's fairs during the year in which the Association participated.

MOTION PICTURES

The demand for motion pictures has continued to increase and the Bureau now has seventeen pictures—fourteen for the medical profession and three for the public. There has been no attempt to build up a large film library but rather to supply information concerning films that may be available elsewhere.

Summary

The Scientific Exhibit at the San Francisco session was marked by very large attendance which constantly filled the halls and corridors on both floors of the exhibit. There were 242 applications for space, of which 161 were accepted. The special exhibits on fractures and anesthesia were outstanding successes.

Association exhibits, dealing with the activities of the Association, were sent out on 124 occasions to forty states.

The demand for motion pictures continues to increase. There has been no attempt to build up a large film library; there are seventeen subjects, however, on the film list, which are almost constantly on loan.

Use of Barbituric Acid and Derivative Drugs

At the annual session of the Association held in Atlantic City in 1937 a resolution pertaining to the sale and promiscuous use of barbituric acid derivatives was submitted to the House of Delegates by Dr. H. A. Luce, Michigan.

Information concerning existing legislation for the control of the sale of these products was compiled by the Bureau of Legal Medicine and Legislation. Laws designed to establish control over the sale of barbituric acid and derivative drugs have recently been enacted in Georgia, Tennessee and Washington, and a bill of similar nature has been passed by both houses of

the legislature in Delaware but at the time of the preparation of this report has not been signed by the governor. Bills on the same subject are pending in the legislatures of California, Kansas, Minnesota and New York, but none had been enacted into law at the time this report was prepared. A similar bill failed of enactment in Indiana. Up to this time laws providing for the regulation of the sale and distribution of barbituric acid and its compounds and derivatives have been enacted and are now in effect in nineteen states. In one state a law for the control of the sale of barbiturates was enacted several years ago but was later repealed.

While the Council on Pharmacy and Chemistry had already given attention to this matter, the Board of Trustees requested that body to prepare a scientific statement for publication in THE JOURNAL, and the Council has prepared an exhaustive report.

Committee on American Health Resorts

Pursuant to resolutions adopted by the House of Delegates at the San Francisco Session, the Board of Trustees has appointed the following Committee on American Health Resorts:

Dr. Bernard Fantus, Chairman, Chicago.
Dr. Walter S. McClellan, Saratoga Springs, N. Y.
Dr. Euclid M. Smith, Hot Springs National Park, Ark.
Dr. M. B. Jarman, Hot Springs, Va.
Dr. William P. Holbrook, Tucson, Ariz.

This committee is now engaged in outlining its plans of work and will no doubt submit a report to the Board of Trustees which can be transmitted to the House of Delegates at its next meeting.

Committee on Distinguished Service Award

After the election of Dr. H. H. Shoulders as Speaker of the House of Delegates, it seemed desirable to have some one designated to serve in his place as Chairman of the Committee on Distinguished Service Award, and the Board of Trustees selected Dr. E. L. Henderson of Louisville, Ky., a member of this House of Delegates, to serve in that capacity. The other members of the Committee on Distinguished Service Award are Dr. John W. Amesse, Denver; Dr. Grant C. Madill, Ogdensburg, N. Y.; Dr. J. D. Brook, Grandville, Mich., and Dr. John F. Hassig, Kansas City, Kan.

The Indictment of the Association

An indictment of the American Medical Association, the Medical Society of the District of Columbia, the Harris County Medical Society, which is a component society of the State Medical Association of Texas, certain members of the Medical Society of the District of Columbia, and certain members of the administrative personnel of the American Medical Association was returned by an additional Grand Jury impaneled at the request of the Department of Justice of the United States. This indictment was reproduced in full in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Dec. 31, 1938.

Only one member of the official personnel of the American Medical Association appeared before the Grand Jury, and that one appeared only for the purpose of producing material taken from the files of the Association in compliance with the terms of subpenas issued at the instance of the Department of Justice. It required the expenditure of a great deal of time and effort on the part of a rather large number of members of the working personnel in the Association's offices to comply with the demands presented through these subpenas, but a sincere and exhaustive effort was made to make the fullest possible compliance.

The Board of Trustees, in accordance with instructions received from the House of Delegates at its special session held in Chicago Sept. 16 and 17, 1938, has engaged counsel and will exert all possible effort to make proper defense before the courts in which the issues involved may be heard.

Ruling of Bureau of Internal Revenue

The House of Delegates was informed at a previous annual session that the Bureau of Internal Revenue of the federal government had issued a ruling to the effect that the American Medical Association is liable for the payment of taxes under the provisions of certain sections of the revenue laws, and that under this ruling the Association would be classified by the Bureau as a business league rather than as a scientific and educational organization, under which classification the Association had always been placed prior to the issuance of the latest ruling of the Bureau of Internal Revenue.

On authorization of the House of Delegates, the Board of Trustees has appealed for a reversal of this ruling, and its appeal has been pending before the proper officials of the Bureau of Internal Revenue for several months, though at the time of the preparation of this report no decision has been handed down. In the meantime, taxes due under the ruling of the bureau have been paid after careful efforts to estimate fully the amounts due.

Several conferences, participated in by the Association's attorneys and attorneys of the Bureau of Internal Revenue, have been held and at one conference three members of the official personnel of the Association were present and received most courteous consideration at the hands of the government officials present. It is expected that a decision in this matter will be made within the near future.

Miscellaneous Matters

A great many matters that are not covered in this report have received official consideration by the Executive Committee of the Board of Trustees at its monthly meetings and by the Board of Trustees at the regular meetings of this body. To discuss all such matters fully would require the presentation of a report of such length as to make it burdensome. However, the Board of Trustees is prepared to submit to the House of Delegates any information that may be desired and that is available to the Board.

Respectfully submitted.

ARTHUR W. BOOTH, Chairman.
AUSTIN A. HAYDEN, Secretary
ROGER I. LEE.
ALLEN H. BUNCE.
RALPH A. FENTON.

CHARLES B. WRIGHT.

ADDENDA TO REPORT OF BOARD OF TRUSTEES

Report of the Committee on Scientific Research for 1938

The committee has followed its policy to support by small grants promising individual research in various fields of medical interest. During the year seventy-three applications have been considered and forty-five grants have been made. In all cases the money has been turned over to the financial officer of the institution in which the grantee works, with the understanding that it would be subject to requisitions by the grantee and that an accurate account of the expenses would be kept. Practically complete results of work under twenty-nine grants have been published or are in course of publication. The results under eighteen grants prior to 1938 are being prepared for publication; in the case of forty-three grants prior to 1938 active work is still in progress, but in several cases reports on results have been published. During the year unexpended balances from grants amounting to $86.57 have been refunded (see financial statement for 1938).

Financial Statement for 1938

Balance, Jan. 1, 1938		$ 4,161.19
Appropriation for 1938		13,750.00
Refund, grant 369		35.00
Refund, grant 370		2.89
Refund, grant 398		48.68
		$17,997.76

The committee believes that its work should be continued and ventures to recommend that the same appropriation be made for 1939 as for 1938; namely, $12,500 for grants in aid of medical research and $1,200 for expenses of the committee.

The financial statement for 1938 is presented, also brief accounts of grants pending at the end of 1937 and a list of grants made in 1938

Respectfully submitted

GRANTS OF COMMITTEE ON SCIENTIFIC RESEARCH

NEW GRANTS—1938

Grant 484 William Antopol, Newark Beth Israel Hospital, Newark, N J, $250 Shwartzman phenomenon

Grant 485 Erwin Chargaff, Columbia University, $400, chemistry and physiology of obstructive jaundice

Grant 486 Ben Vidgoff, University of Oregon Medical School $300, inhibitory hormone of the germinal epithelial cells of the testis and its effect on the rat prostate

Grant 487 Felix Saunders, University of Chicago, $250, isolation of growth factors

Grant 488 Lester R Dragstedt and G M Dack, University of Chicago $600, relationship of Bacterium necrophorum to ulcerative colitis

Grant 489 Alexander S Wiener, Jewish Hospital of Brooklyn, $200, agglutinogens in human blood and studies on Kline test

Grant 490 Peter Heinbecker, Washington University School of Medicine, $500, pituitary regulation of water balance in the dog

Grant 491 Charles G Johnston, Wayne University College of Medicine, Detroit, $660, intestinal obstruction

Grant 492 Solomon Strouse and B O Raulston, University of Southern California, $500, sodium potassium relationship in diabetes

Grant 493 George M Curtis, Ohio State University, $600, iodine and calcium metabolism in thyroid disease

Grant 494 Catharine Macfarlane, Woman's Medical College of Pennsylvania, $480, value of periodic pelvic examination in detecting cancer of the uterus

Grant 495 Lincoln Opper and Barnett Sure, University of Arkansas, $600, relation of vascular disease to avitaminosis in the rat

Grant 496 Samuel Soskin Michael Reese Hospital, Chicago, $500, laboratory tests for endocrine dysfunction

Grant 497 Albert P Krueger, University of California, $300, bacteriophage

Grant 498 Henry Laurens, Tulane University, $351 50, lowering of arterial pressure by carbon arc radiation

Grant 499 Robert W Virtue, University of Denver, $365, formation of bile acids

Grant 500 Moore E Mills and Francis D Gunn, Northwestern University Medical School, $300, experimental pulmonary tuberculosis in dogs

Grant 501 Arthur H Smith, Wayne University College of Medicine, Detroit, $200, serum proteins in relation to blood volume

Grant 502 Charles P Sheldon, Harvard University, $31 25, respiration in pregnancy and labor

Grant 503 R C Robb, Syracuse University College of Medicine, $800, diseases in twins

Grant 504 Wallace M Yater, Georgetown University Medical School, $500 histopathology of "bundle branch" block

Grant 505 Elizabeth S Russell, Roscoe B Jackson Memorial Laboratory, Bar Harbor, Me, $250, genetics of tumors in the fruit fly

Grant 506 Harry Sobotka, Mount Sinai Hospital, New York, $150, monomolecular layers of physically active substances

Grant 507 Joseph H Roe, George Washington University, $500, vitamin C content of plant, animal and tumor tissue

Grant 508 Louis N Katz, Michael Reese Hospital, Chicago, $250 factors influencing activities of the heart

Grant 509 Roe E Remington, Medical College of the State of South Carolina, $400, iodine deficiency in the rat

Grant 510 Erma A Smith, Iowa State College, $150, influence of various substances on gastrointestinal motility

Grant 511 Charles W Turner, University of Missouri, $500 relation of thyrotropic hormone of anterior pituitary to pregnancy and lactation

Grant 512 Barnes Woodhall Duke University Hospital, $350, reactions to implanted Shope rabbit papilloma by cerebral tissue

Grant 513 John S Lawrence, University of Rochester, $350, transmissible agranulocytosis in the cat

Grant 514 Samuel R M Reynolds, Long Island College of Medicine, $200, action of oestrin on small blood vessels

Grant 515 Robert R Sealock, University of Rochester, $400, relation of metabolism of melanin pigment precursors to vitamin C requirements

Grant 516 Charles O Warren Jr, Cornell University Medical College, $300, metabolism of bone marrow

Grant 517 Irving J Wolman Children's Hospital of Philadelphia, $170, lipoid pneumonia

Grant 518 Harold D West, Meharry Medical College, $100, synthesis of *dl* threonine

Grant 519 D B Phemister and Harwell Wilson, University of Chicago, $400 mechanism of blood pressure in sympathectomized dogs

Grant 520 H E Carter, University of Illinois, $250, betaines of aminohydroxy acids

Grant 521 Rucker Cleveland, Vanderbilt University, $400, cytology of endometrium

Grant 522 Ludwig A Emge, Stanford University School of Medicine, $500, relation of sex hormones to tumor growth

Grant 523 Frederick A Fender, Stanford University School of Medicine, $150, development of device for direct neurologic stimulation

Grant 524 Ernest Spiegel Temple University, $300 physicochemical factors influencing the excitability of the central nervous system

Grant 525 A R Buchanan, University of Mississippi, $400, vestibular mechanism

Grant 526 Charles F Code, University of Minnesota, $400, metabolism of histamine

Grant 527 Alexander Levy, University of Oregon Medical School $300, occlusion of the coronary arteries

Grant 528 Frank Co Tui, New York University, $150, relation between Shwartzman agent and pyrogen

STATE OF WORK UNDER PREVIOUS GRANTS

1 COMPLETED DURING THE YEAR

Grant 174, 1930 Alfred R Roos, College of Medical Evangelists, Loma Linda, Calif, $1,455, hay fever pollens in the Southwest The reports and maps describing the results of work on the different groups of plants will be published by the Department of Agriculture of the state of California

Grant 277, 1933 Gustav Zechel, University of Illinois College of Medicine, $260, study of growing malignant cells by moving photomicrographs Zechel, Gustav, and Morgenster, O A Timing Device for Talking Motion Pictures, *Science* **81**: 23, 1935 Zechel Gustav A Simple Method of Obtaining Blood from the Rat in the Preparation of Plasma for Tissue Culture, *Arch f exper Zellforsch* **18**: 142, 1935 Zechel, Gustav An Improved Tissue Culture Chamber, *Science* **87**: 264, 1938

Grant 343, 1934 John Guttman, Post Graduate Medical School and Hospital, $400, relation between electrical disturbances in cochlea and the sensation of hearing Guttman, John, and Barrera, S E: The Electrical Potentials of the Cochlea and Auditory Nerve in Relation to Hearing, *Am J Physiol* **120**: 666, 1937

Grant 348 1935 Phillips Thygeson State University of Iowa, $400, trachoma and 'inclusion virus" disease of the genito urinary tract Thygeson, Phillips and Mengert, W F The Virus of Inclusion Conjunctivitis *Arch Ophth* **15**: 377, 1936 Thygeson Phillips, Proctor, Francis I, and Richards, Polk Etiologic Significance of the Elementary Body in Trachoma *Am J Ophth* **18**: 811, 1935 Thygeson, Phillips, and Richards, Polk Nature of the Filtrable Agent of Trachoma *Arch Ophth* **20**: 569, 1938 Thygeson Phillips The Cultivation of Human Conjunctival and Corneal Epithelium in Vitro, *Am J Ophth* to be published

Grant 356 1935 Jay C Davis University of Minnesota $500 coronary flow and lesions of the aortic valves See grant 463 1937 Davis J C An Analysis of the Factors Involved in the Changes in Coronary Flow in Aortic Stenosis and Regurgitation, *Am J Physiol* **123**: 50, 1938

Grant 365, 1935 Ludwig A Emge, Stanford University School of Medicine, $300 effect of castration on malignant tumors Emge Ludwig A, and Murphy, Kathleen M Effect of Rapidly Repeated Pregnancies on Transplantable Mammary Rat Adenofibromas *Proc Soc Exper Biol & Med* **37**: 620, 1938 Emge Ludwig A, Murphy, Kathleen M, and Schilling, Walter Effect of Theelin on Transplantable Mammary Rat Adenofibroma, *ibid* **38**: 21, 1938 Emge Ludwig A Schilling Walter and Wulff, L M R Effect of Pregnancy on the Growth of Rat Sarcoma *ibid*, p 338 Emge, Ludwig A Sarcomatous Degeneration of Transplantable Mammary Adenofibroma of the White Rat *Arch Path* **26**: 429, 1938 Murphy, Kathleen M, Schilling, Walter and Emge Ludwig A Effect of Prolonged Theelin Injections on Transplantable Mammary Adenofibroma, *Proc Soc Exper Biol & Med* **39**: 298, 1938 Emge, Ludwig A, and others The Influence of Long Continued Injections of Estrogen on Mammary Tissue, *Am J Obst & Gynec* **36**: 750 1938

Grant 370, 1935 Richard L Crouch University of Missouri $500 connections of diencephalon (refund $2 89) Crouch Richard L, and Thompson, John K The Efferent Fibers of the Thalamus of Macacus Rhesus *J Comp Neurol* **69**: 255 1938 Crouch, Richard L and Thompson, John K Termination of the Brachium Conjunctivum in the Thalamus of the Macaque Monkey, *ibid*, p 449 Other papers in course of publication

Grant 378, 1935 Wallace M Yater, Georgetown University Hospital Washington, D C, histopathologic basis of "bundle branch" block See grant 504 1938 Yater, Wallace M The Morbid Anatomy of Bundle Branch Block, *M Ann District of Columbia* **7**: 1 and 54 1938 Yater, Wallace M Pathogenesis of Bundle Branch Block *Arch Int Med* **62**: 1, 1938

Grant 380, 1935 N W Popoff, Highland Hospital, Rochester N Y, $600, arteriovenous anastomosis Popoff, Nicholas W Epithelial Functional Rejuvenation, *Arch Path* to be published

Grant 402, 1936 C H Thienes and L T Samuels, University of Southern California, $500 carbohydrate metabolism as influenced by the hypophysis See grant 453, 1937 Samuels, L T, and others Glycogen Formation After Alanine Administration in Adrenalectomized Animals *Proc Soc Exper Biol & Med* **35**: 538, 1937 Ball H A and Samuels, L T The Effect of Cortical Extract on the Glucose Tolerance of Adrenalectomized Rats, *ibid*, p 633 Samuels, L T, Schott, H F and Ball Howard A Carbohydrate Metabolism Studies in Hypophysectomized Rats II The Relation of the Hypophysis and Adrenal Cortex to the Removal of Excess Glucose from the Blood of Rats *Am J Physiol* **120**: 649, 1937

Grant 418, 1936 Frank W Allen, University of California $200, nucleotide of the red corpuscles See grant 464, 1937 Euler, John J, and Allen Frank W The Catabolism of the Purine Nucleotides I The Relation to Glycolysis in the Blood of the Rabbit, *J Biol Chem* **123**: 655 1938

Grant 427, 1936 Helen S Mitchell Massachusetts State College $300, nutritional cataract in rats Mitchell, Helen S, and Cook Gladys M Influence of Protein or Cystine Intake on Cataract Producing Action of Galactose, *Proc Soc Exper Biol & Med* **36**: 806, 1937 Mitchell Helen S, Merriam, Oreata A, and Cook Gladys M The Relation of Ingested Carbohydrate to the Type and Amount of Blood and Urine Sugar and to the Incidence of Cataract in Rats, *J Nutrition* **13**: 501, 1937 Mitchell Helen S, and Cook, Gladys M Galactose Cataract in Rats, *Arch Ophth* **17**: 22, 1938

Grant 428, 1936 D B Phemister, K Grimson and H Wilson University of Chicago, $400, effect of sympathectomy on blood pressure in dogs See grant 476, 1937 Grimson, Keith S, Wilson, Harwell and Phemister, Dallas B The Early and Remote Effects of Total and Partial Paravertebral Sympathectomy on Blood Pressure, *Ann Surg* **106**: 801, 1937

Grant 430, 1936 S W Ranson, Northwestern University Medical School, $315, fever producing agents Ranson S W Jr Fever Induced by the Intravenous Injection of Typhoid Paratyphoid Vaccine *Arch Int Med* **61**: 285, 1938 Other papers in course of publication

Grant 433, 1936 Frederick Lemere, Eastern State Hospital, Medical Lake, Wash $500, Berger brain rhythms in psychotic patients Lemere Frederick Effects of Electroencephalogram of Various Agents Used in Treating Schizophrenia, *J Neurophysiol* **1**: 590, 1938

Grant 435, 1936 Warren O Nelson, Wayne University College of Medicine Detroit, $300, effect of synthetic androgenic substances See grant 481, 1937 Nelson, Warren O, and Merckel, Charles G Effects of Androgenic Substances in the Female Rat, *Proc Soc Exper Biol & Med* **36**: 823, 1937 Nelson, Warren O, and Merckel, Charles G Maintenance of Spermatogenesis in Testis of the Hypophysectomized Rat with Sterol Derivatives, *ibid*, p 825 Nelson, Warren O, and Hickman, Jane Effect of Oestrone on Hypophyses and Reproductive Organs of Thyroidectomized Rats, *ibid*, p 828 Nelson, Warren O Some Factors Involved in the Control of the Gametogenic and Endocrine Functions of the Testis, *Cold Spring Harbor Symposia on Quantitative Biology* **5**: 123, 1937 Nelson, W O, and Merckel C F Maintenance of Spermatogenesis in Hypophysectomized Mice with Androgenic Substance *Proc Soc Exper Biol & Med* **38**: 737, 1938

Grant 436, 1936 Albert P Krueger, University of California $300 nature of bacteriophage See grant 497, 1938 Krueger, A P and Mundell J H Effect of Phage on Electrokinetic Potential of Susceptible Cells, *Proc Soc Exper Biol & Med* **36**: 317, 1937 Krueger A P The Mechanism of Bacteriophage Production *Science* **86** 39 1937 Scribner, I J, and Krueger, A P The Effect of NaCl on the Phage Bacterium Reaction, *J Physiol* **21**: 1, 1937 Krueger Albert P, and Tong, Jacob The Relationship Between Bacterial Growth and Phage Production, *ibid*, p 137 Krueger, A P, and Struetmann W L Effect of Sodium Sulfate on the Phage Bacterium Reaction *J Gen Physiol*, to be published Krueger, A P, and Mundell J H Demonstration of Phage Precursor in the Bacterial Cell, *Science* to be published

Grant 438, 1937 Irving Graef, New York University, $300 pulmonary reactions to lipids and mineral oils Graef Irving, Kaufmann William, and Kaplan Leo Experimental Studies of Tissue Reactions to Lipids I The Formation of Acid Fast Membranes Around Certain Oils and Waxes, *Arch Path* **26**: 914, 1938 Other papers in course of publication

Grant 439, 1937 Moore A Mills, Northwestern University Medical School $300, experimental pulmonary tuberculosis in the dog See grant 500 1938 Mills, Moore A, and Colwell, Charlotte A Cutaneous Reactivity to Tuberculin in the Dog, *Proc Soc Exper Biol & Med* **37**: 470, 1937 Mills, Moore A, Gunn, Francis D and Barth E E Experimental Pulmonary Tuberculosis in the Dog *J Bact* **35** 453 1938

Grant 440 1937 M M Wintrobe, Johns Hopkins University $700 red corpuscles Wintrobe Maxwell M, Mitchell D M and Kolb L C Sensory Neuron Degeneration in Vitamin Deficiency, *J Exper Med* **68**: 207, 1938 Wintrobe, Maxwell M Experiments with Young Pigs on an Artificial Diet, to be published

Grant 446, 1937 Samuel Soskin, Michael Reese Hospital Chicago $500 hormone assay of blood and urine in endocrine dysfunction See grant 496 1938 Freed, S C, Mesirow, S D, and Soskin Samuel On the Composite Nature of the Estrus Phenomenon *Endocrinology* **21**: 731 1937 Freed, S C, and Soskin, Samuel Cyclic Inhibitory Influence of the Rat's Ovary on the Uterine Response to Estrin *Proc Soc Exper Biol & Med* **38**: 391, 1938

Grant 454, 1937 George M Curtis, Ohio State University $600 iodine and calcium balance in thyroid disease See grant 493 1938 Curtis George M, and Puppel, Italo D The Iodine Metabolism in Exophthalmic Goiter, *Ann Surg* **108**: 574, 1938 Puppel Italo D and Curtis, George M The Iodine Balance in Exophthalmic Goiter *Arch Path* **26**: 1093, 1938

Grant 457, 1937 James B Hamilton Albany Medical College $450 testicular descent by administration of male hormone Hamilton James B The Effect of Male Hormone upon the Descent of the Testes *Anat Rec* **70**: 531 1938 Hamilton, James B, and Hubert Gilbert Effect of Synthetic Male Hormone Substance on Descent of Testicles in Human Cryptorchidism, *Proc Soc Exper Biol & Med* **39** 4 1938

Grant 459 1937 John S Lawrence, Strong Memorial Hospital Rochester N Y $450, antiserum for white blood cells See grant 513, 1938 Lawrence, J S, and Syverton J T Spontaneous Agranulocytosis in the Cat, *Proc Soc Exper Biol & Med* **38**: 914 1938 Lawrence John S, Pearse Herman E, and Mider G B The Effect of Experimental Neutropenia on the Healing of Wounds *Arch Path* to be published

Grant, 461, 1937 Roe E Remington, Medical College of the State of South Carolina, $400, quantitative effect of iodine deficiency in the rat See grant 509, 1938 Remington Roe E Effect of Chloride on the Thyroid Gland, *Proc Soc Exper Biol & Med* **37**. 652 1938 Remington, Roe E, and Remington John W Effect of Enhanced Iodine Intake on Growth and on the Thyroid Glands of Normal and Goitrous Rats, *J Nutrition* **15**: 539, 1938 Remington Roe E Does Fat in the Diet Affect the Thyroid *ibid*, to be published Harris Philip L and Remington, Roe E The Effect of Yeast and of Thiamin on the Production of Low Iodine Goiter, *ibid*, to be published

Grant 468 1937 Valy Menkin, Harvard Medical School $300 mechanism of inflammation Menkin, Valy Studies on Inflammation XIV Isolation of the Factor Concerned with Increased Capillary Permeability in Injury, *J Exper Med* **67**. 129, 1938 Menkin Valy Studies on Inflammation XV Concerning the Mechanism of Cell Migration, *ibid*, p 145 Menkin, Valy Studies on Inflammation XVI On the Formation of a Chemotactic Substance by Enzymatic Action ibid, p 153 Menkin, Valy Mechanism of Inflammation *Arch Path* **24**: 65, 1938 Menkin Valy The Role of Inflammation in Immunity *Physiol Rev* **18**: 366 1938 Menkin Valy Studies on Inflammation XVII Direct Effect of Changes in the Hydrogen Ion Concentration on Leukocytes *Arch Path* to be published

Grant 470, 1937 Peter Heinbecker, Washington University School of Medicine $350, pituitary regulation of water exchange and effect of diet on dextrose tolerance and insulin response in dogs See grant 490 1938 White, H L, and Heinbecker, Peter Observations on Creatinine and Urea Clearances, on Responses to Water Ingestion and on Concentrating Power of Kidneys in Normal Diabetes Insipidus and Hypophysectomized Dogs, *Am J Physiol* **123** 566, 1938

Grant 475 1937 Joseph T King, University of Minnesota $350 physiology and sulfanilamide King, Joseph T The Effect of Sulfanilamide on Blood Leukocytes, *Am J Physiol* **123**: 119, 1938 King Joseph T, Henschel, Austin F, and Green Beryl S Influence of Prontosil Soluble on Beta Hemolytic Streptococci Growing in Tissue Culture Media, *Proc Soc Exper Biol & Med* **38**: 810, 1938 King Joseph T; Green, Beryl S, and Henschel Austin F Response of Leukocytes to Colonies of Streptococci Growing in Tissue Culture Media *ibid*, p 812

Grant 476 D B Phemister and Keith Grimson, University of Chicago, $400, effect of sympathectomy in dogs See grants 428, 1936, and 519, 1938

2 INCOMPLETE

A Work under the grant completed, account rendered of expenses but results not published fully

Grant 286, 1933 T H Pike, Columbia University, $600, the effects of successive experimental lesions of the nervous system

Grant 308, 1933 John L Ulrich, Johns Hopkins University, $250, the reflex system in the cat See grant 372, 1935

Grant 309, 1933 Carroll L Birch, University of Illinois School of Medicine, $300, assay of urine for sex hormone of the anterior pituitary

Grant 367, 1935 Robert Gault and A C Ivy, American Institute for the Deaf Blind, Evanston, Ill, $600, mechanical stimulation of the vibrotactile organs See grant 412, 1936

Grant 379, 1935 Victor C Myers (Donald E Bowman), Western Reserve Medical School, $650, chemical test for pregnancy

Grant 382, 1935 L Goodman, A J Geiger and L Chilborn, Yale University, $250, antiraneme principle

Grant 398, 1936 George A Emerson, West Virginia University, Morgantown $175, metabolic products of sympathomimetic amines (refund, $48 68)

Grant 401, 1936 W. T Dawson, University of Texas, Galveston, $200, toxicity of cardiac glucosides

Grant 407, 1936 Ralph I Dorfman, Louisiana State University, $250, estrogenic substance in human urine and other estrogenic compounds

Grant 412, 1936· Robert H Gault and A C Ivy, American Institute for Deaf Blind, Evanston, Ill, $400, stimulation of vibrotactile organs by mechanical vibrations See grant 367, 1935

Grant 416, 1936 Jean Broadhurst, Teachers College, Columbia University, $200, inclusion bodies in the female genital area

Grant 431, 1936 Benjamin Harrow, College of the City of New York, $200 purification of the hyperglycemic factor in urine

Grant 447, 1937 R C Herrin, University of Wisconsin, $400, urea clearance

Grant 448, 1937 Warren H Cole, University of Illinois College of Medicine, $500, cholesterol tolerance as an index of hyperthyroidism and study of excretory function of the liver

Grant 452, 1937 G Albin Matson, Montana State University, Missoula, $100, antigenic properties of certain chemical substances

Grant 465, 1937. Fred L Humoller, Loyola University School of Medicine, Chicago, $300, toxic principles in culture fluids of Bacterium enteritidis

Grant 469, 1937 Joseph Krafka Jr, University of Georgia School of Medicine, $370, elastometric measurements on smooth muscle and connective tissue Krafka, Joseph, Jr Comparative Study of the Histophysics of the Aorta, *Am J Physiol*, to be published

Grant 471, 1937 Timothy Leary, Office of Medical Examiner, Boston, $500, early atherosclerotic processes and relation of cholesterol to neoplastic growth

Grant 493, 1938 George M Curtis, Ohio State University, $600, iodine and calcium metabolism in thyroid disease See grant 454, 1937

B ACTIVE WORK STILL IN PROGRESS

Grant 254, 1932 J Lisle Williams, Rush Medical College, Chicago, $200, decreased dextrose tolerance in acute infectious diseases

Grant 372, 1935 John L Ulrich, Johns Hopkins University, $450, cerebral functions in the action of antagonistic muscles See grant 308, 1933

Grant 310, 1934 Lay Martin, Johns Hopkins University, $150, study of gastric juice See grant 462, 1937

Grant 324, 1934 William deB MacNider, University of North Carolina, $285, study of artificial circulation in the kidney

Grant 337, 1934 James L O'Leary, Washington University, $245, Loven reflexes Bishop, G H, and O'Leary, James Pathways Through the Sympathetic Nervous System in the Bullfrog, *J Neurophysiol* **1:** 442 1938

Grant 344, 1934 Paul L Day and W C Langston, University of Arkansas School of Medicine, $300, effect of withdrawal of vitamin G from diet of monkeys Shukers Carroll F, Langston, William C, and Day, Paul L The Normal Blood Picture of the Young Rhesus Monkey, *Folia haemat* **60:** 416, 1938 Day, Paul L, Langston, William C, and Darby, William J Failure of Nicotinic Acid to Prevent Nutritional Cytopenia in the Monkey, *Proc Soc Exper Biol & Med* **38:** 860, 1938 Langston, William C, Darby, William J, Shukers, Carroll F, and Day, Paul L· Nutritional Cytopenia (Vitamin M Deficiency) in the Monkey, *J Exper Med* **68:** 923, 1938

Grant 350, 1935 Frederic A Gibbs, Harvard University School of Medicine, *$100, fiber system in the cat's brain concerned in convulsions* Gibbs, Erna Leonhardt, and Gibbs, Frederic Andrews A Purring Center in the Cat's Brain, *J Comp Neurol* **64:** 209, 1936

Grant 355, 1935 Royall M Calder, San Antonio, Texas, $150, mechanism of pneumococcic inflammation

Grant 388, 1935 Tracy J Putnam, Boston City Hospital, Boston, $150, effect of low voltage current on nervous sytem Alexander, Leo Clinical and Neuropathological Aspects of Electrical Injuries, *J Indust Hyg & Toxicol* **20:** 191, 1938 Alexander, Leo Electrical Injuries to Central Nervous System, *M Clin North America* **22:** 663, 1938

Grant 397, 1936 R F Hanzal, Western Reserve University, $150, source of endogenous uric acid and the effects of methylated xanthines on its secretion

Grant 410, 1936 H E Eggers, University of Nebraska, $200, effect of tetra methyl arsonium gluconate on human cancer

Grant 413, 1936 Philip Levine, Newark Beth Israel Hospital, Newark, N J, $350, bacteriophage action in the dysentery group Levine, Philip, and Perlstein, David Phage Specific Heat Labile Factors in B Dysenteriae Sonne, *Proc Soc Exper Biol & Med.* **36:** 295, 1937

Grant 415, 1936 Gordon H Scott, Washington University, St Louis, $300, lead and aluminum in cerebrospinal fluid Scott, Gordon H, and McMillen, J Howard Spectrographic Analyses of Human Spinal Fluid, *Proc Soc Exper. Biol & Med* **35:** 287, 1936 McMillen, J Howard, and Scott, Gordon H · Spectrographic Studies of Lead in Human Blood, *ibid*, p 364

Grant 420, 1936 Arthur Knudson, Albany Medical College, $400, synthesis of cholesterol in the animal body

Grant 423, 1936 Alfred Gilman, Yale University, $300, physiology of the antidiuretic hormone of the posterior pituitary Gilman, Alfred, and Goodman, Louis Secretory Response of the Posterior Pituitary to the Need for Water Conservation, *J Physiol* **90:** 113, 1937

Grant 434, 1936 Wilbert H McGaw, Western Reserve University, $500, sound conduction in fractured bones

Grant 441, 1937· Edward S West and G E Burget, University of Oregon Medical School, $350, diuretic action and chemical metabolism of sorbitol

Grant 442, 1937 S J Crowe, Johns Hopkins University, $480, physiology of hearing

Grant 443, 1937 Ernest Carroll Faust, Tulane University, $300, epidemiology of trichinosis in New Orleans Sawitz, Willi Are Post mortem Statistics on Trichinosis Valid for the Living Population? *Am J Pub Health* **27:** 1023, 1937 Sawitz, Willi Studies on Trichinella Spiralis in the New Orleans Area *Arch Path*, to be published

Grant 444, 1937 George Herrmann University of Texas, Galveston, $300, chemistry of the heart muscle Herrmann, George, and Erhard, Peter Total Creatinine, Phosphates, Calcium and Potassium in Normal and Infarcted Myocardium of the Dog, *Proc Soc Exper Biol & Med* **38:** 35, 1938

Grant 445, 1937· Paul M Levin, Johns Hopkins University, $250, cerebral efferent tracts in primates Levin, Paul M A Nervous Structure in the Pineal Body of the Monkey, *J Comp Neurol* **68:** 405, 1938 Levin, Paul M, and Bradford, F Keith The Exact Origin of the Corticospinal Tract in the Monkey, *ibid*, p 411

Grant 449, 1937 Charles W Turner, University of Missouri, $250, pituitary hormones See grant 511, 1938

Grant 451, 1937 Frank Co Tui, New York University, $200, Schwartzman phenomenon and pyrogenic reaction See grant 528, 1938

Grant 453, 1937 L T Samuels and C H Thienes, University of *Southern California, $300, hypophysis in metabolism of carbohydrate fat* and metabolism See grant 402, 1936

Grant 455, 1937 Elizabeth S Russell, Roscoe B Jackson Memorial Laboratory, Bar Harbor, Me, $225, genetics of tumors in the fruit fly See grant 505, 1938

Grant 456, 1937 Ira A Manville, University of Oregon Medical School $500, relation of degenerative changes in connective tissue to glycuronic metabolism

Grant 458, 1937 Orthello R Langworthy, Johns Hopkins University, $350, effect of ovulation and pregnancy on smooth muscle of urinary bladder Langworthy, O R, and Brack, C B The Effect of Pregnancy and Corpus Luteum on Vesical Muscle, *Am J Obst & Gynec*, to be published

Grant 460, 1937· M G Seelig, Barnard Free Skin and Cancer Hospital, St Louis, $250, carcinogenicity of heterocyclic hydrocarbons

Grant 462, 1937 Lay Martin, Johns Hopkins University, $200, gastric juice See grant 310, 1934

Grant 463, 1937 Jay Conger Davis, Minneapolis, $600, action of certain drugs on the coronary arteries See grant 356, 1935

Grant 464, 1937 Frank W Allen, University of California, $200, relation of nucleotide fraction of red corpuscles to glycolysis See grant 418, 1936

Grant 466, 1937 G Louis Weller Jr, George Washington University, $275, effect of sodium pyruvate and other substances on vitamin B deficiency

Grant 467, 1937 B O Barnes, Rush Medical College, $300, extract of adrenals

Grant 472, 1937 Margaret Lasker, Yonkers, N Y, $200, incidence of pentosuria and fructosuria

Grant 473, 1937 Roy H Turner, Tulane University, $400, physiology of blood vessels in man

Grant 474, 1937 Marion Fay, Woman's Medical College of Pennsylvania, $275, biochemistry of strontium

Grant 477, 1937 Irving J Wolman, University of Pennsylvania, $335, lipoid pneumonia See grant 517, 1938

Grant 478, 1937 Martin Silberberg, Washington University School of Medicine, $600, influence of hormones on bone growth Silberberg, Martin, and Silberberg, Ruth Influence of Cattle Anterior Pituitary Extract on Endochrondal Ossification in Young Ovariectomized Pigs, *Proc Soc Exper Biol & Med* **37:** 446, 1938

Grant 479, 1937 Tracy J Putnam, Boston City Hospital, $200, injuries to the cervical cord

Grant 480, 1937 Amy L Daniels, State University of Iowa, $250, relation of fluorine to physiologic function

Grant 481, 1937 Warren O Nelson, Wayne University College of Medicine, Detroit, $200, synthetic androgenic substances See grant 435, 1936

Grant 482, 1937 Warren O Nelson, Wayne University College of Medicine, Detroit, $400, effect of thymus gland on the growth of rats Janes, Ralph G, and Segaloff, Albert Growth and Metamorphosis of Anuran Larvae on Thymus Extracts, *Proc Soc Exper. Biol & Med* **39:** 172, 1938

Grant 483, 1937: J. M. Johlin, Vanderbilt University School of Medicine, $250, attenuation of toxins by interfacial adsorption. Johlin, J. M.: Attenuation of Toxins by Interfacial Adsorption, *Proc. Soc. Exper. Biol. & Med.* **38**: 568, 1938.

3. No Results Published

Grant 386, 1935: E. V. McCollum, Johns Hopkins University, $150, adaptation of the eyes to subdued light and its relation to vitamin A (refund, $19.65).

Report of Committee on Therapeutic Research

The Committee on Therapeutic Research, a standing committee of the Council on Pharmacy and Chemistry, encourages scientific investigations in the field of therapeutics by providing funds for the prosecution of necessary research.

During the year 1938 the Committee issued thirty-seven new grants. A detailed list of these grants, together with a list of publications during 1938, and of unexpired grants made before Jan. 1, 1938, will be found in the appendix to this report.

The following is a list of the investigations conducted with the assistance of grants made by the Committee on Therapeutic Research, reports of which were published during 1938:

1. The Effect of Supplementary Lysine, Methionine and Cystine on the Production of Fatty Livers by High Fat Diets Containing Gliadin, Helen F. Tucker and Henry C. Eckstein: *J. Biol. Chem.* **126**: 117 (Nov.) 1938.

2. The Effect of Sodium Amytal, Sodium Barbital and Nembutal on the Electrocardiogram, Roberta Hafkesbring and Winona MacCalmont: *J. Pharmacol. & Exper. Therap.* **64**: 43 (Sept.) 1938.

3. Clinical Excretion of Bismuth: V. Excretion of Sobisminol and of Some Other Bismuth Preparations for Oral Administration, Torald Sollmann, H. N. Cole, Katharine Henderson and collaborators: *Arch. Dermat. & Syph.* **37**: 993 (June) 1938.

4. Bismuth Studies: V. The Bismuth Absorption from the Site of Injection in Dogs, Torald Sollmann and Katharine Henderson: *Am. J. Syph., Gonor. & Ven. Dis.* **22**: 286 (May) 1938.

5. Clinical Excretion of Bismuth: VII. The Autopsy Distribution of Bismuth in Patients After Clinical Bismuth Treatment, Torald Sollmann, H. N. Cole, Katharine Henderson and collaborators: *Am. J. Syph., Gonor. & Ven. Dis.* **22**: 555 (Sept.) 1938.

6. Bismuth Studies: VIII. Bismuth Distribution in Dogs Following Intramuscular Injection of a Single Dose of Various Bismuth Preparations, Torald Sollmann and Katharine Henderson: *Am. J. Syph., Gonor. & Ven. Dis.* **22**: 739 (Nov.) 1938.

7. Combination Courses of Bismuth Administration, Torald Sollmann, H. N. Cole, Katharine Henderson and collaborators: *J. A. M. A.* **111**: 2175 (Dec. 10) 1938.

8. The Effect of Prontosil and Related Compounds upon the Chemotropism of Leukocytes, Dale Rex Coman: *Am. J. M. Sc.* **196**: 273 (Aug.) 1938.

9. Studies in Chemotropism: Source of Substances Attracting Polymorphonuclear Leukocytes to Bacteria, Harold M. Dixon and Morton McCutcheon: *Proc. Soc. Exper. Biol. & Med.* **38**: 378 (April) 1938.

10. The Action of Histidine on the Gastrointestinal Tract, Louis S. Goodman and Philip A. Bearg: *Am. J. Digest. Dis.* **5**: 117 (April) 1938.

11. The Action of Excess Na, Ca and K on the Coronary Vessels, L. N. Katz and E. Lindner: *Am. J. Physiol.* **124**: 155 (Oct.) 1938.

12. Effects of Various Drugs on the Coronary Circulation of the Denervated Isolated Heart of the Dog and Cat: I. Observations on Epinephrine, Acetylcholine, Acetyl-β-Methylcholine, Nitroglycerin, Sodium Nitrite, Pitressin and Histamine, L. N. Katz, E. Lindner, W. Weinstein, D. I. Abramson and K. Jochim: *Arch. internat. de pharmacodyn. et de thérap.* **49**: 400 (Aug. 31) 1938.

13. The Distribution of the Coronary Blood Flow, L. N. Katz, K. Jochim and W. Weinstein: *Am. J. Physiol.* **122**: 252 (April) 1938.

14. Further Studies on the Pulse Wave in the Aorta and Its Branches, Philip Dow and W. F. Hamilton: *Am. J. Physiol.* **123**: 54 (July) 1938.

15. Blood Pressure Values in Street Dogs, W. F. Hamilton, E. R. Pund, A. W. Simpson, Jr., G. M. Colson and H. W. Coleman: *Am. J. Physiol.* **123**: 88 (July) 1938.

16. Pulmonary Arterial, Venous and Differential Pressure in the Unanesthetized Dog, R. A. Woodbury, W. F. Hamilton and Elkin Vogt: *Am. J. Physiol.* **123**: 220 (July) 1938.

17. The Rate of Utilization of Vitamin A and Carotene by Normal and Diabetic Dogs, Elaine P. Ralli and Arthur C. Pariente: *Am. J. Physiol.* **123**: 166 (July) 1938.

18. Relation Between Size of Dose and Lipotropic Effect of Choline Chloride in Mice, Mary Scott Welch and Arnold DeM. Welch: *Proc. Soc. Exper. Biol. & Med.* **39**: 5 (Oct.) 1938.

19. Lipotropic Action of Certain Compounds Related to Choline Chloride, Arnold DeM. Welch and Mary Scott Welch: *Proc. Soc. Exper. Biol. & Med.* **39**: 7 (Oct.) 1938.

20. The Chemical Nature and Nomenclature of Choline Derivatives, Arnold DeM. Welch: *Science* **88**: 333 (Oct. 7) 1938.

21. A New Method for Determination of Iodine in Five Cubic Centimeters of Blood or Other Biological Material, J. F. McClendon, A. Calvin Bratton, Ralph V. White and William C. Foster: *J. Biol. Chem.* **123**: 699 (May) 1938.

22. Determination of "Hormone Iodine" in 5 Cc. Blood, J. F. McClendon and William Foster: *Proc. Soc. Exper. Biol. & Med.* **39**: 230 (Nov.) 1938.

23. Determination of Iodine in Drinking Water, Urine and Substances Containing Only About 1,000 Times as Much Organic Matter as Iodine, A. C. Bratton, J. F. McClendon, William Foster and Ralph White, *Indust. & Engin. Chem.* **10**: 600 (Oct. 15) 1938.

24. Changes With Age in the Cardiac Output in Adult Men, William Hall Lewis Jr.: *Am. J. Physiol.* **121**: 517 (Feb.) 1938.

25. Experimental Infection in the Mouse Produced by Intratracheal Inoculation with Hemophilus Pertussis, William L. Bradford: *Am. J. Path.* **14**: 377 (May) 1938.

26. An Attempt to Increase Resistance to Pertussis in Newborn Infants by Immunizing Their Mothers During Pregnancy, John A. Lichty Jr., Betty Slavin and William L. Bradford: *J. Clin. Investigation* **17**: 613 (Sept.) 1938.

During 1938 the following grants were issued:

Grant 337: Harald G. O. Holck, associate professor of pharmacology, University of Nebraska College of Pharmacy, $150, to investigate the relation of sex differences to the action of certain drugs.

Grant 338: Torald Sollmann, dean and professor of pharmacology and Materia Medica, Western Reserve University School of Medicine, and Joseph Seifter, Western Reserve University School of Medicine, $250, to investigate the action of certain antimony and arsenic compounds.

Grant 339: Katharine Henderson, Department of Pharmacology, Western Reserve University School of Medicine, $300, to investigate bismuth preparations.

Grant 340: A. R. McIntyre, professor of physiology and pharmacology, University of Nebraska College of Medicine, $100, to investigate the effects of the digitaloid bodies on the metabolism of dextrose by the cardiac musculature.

Grant 341: Maurice Rosenthal, formerly instructor in pathology, Long Island College of Medicine, $200, to investigate radium poisoning.

Grant 342: W. L. Bradford, associate professor of pediatrics, University of Rochester School of Medicine, $300, to investigate pertussis.

Grant 343: Morton McCutcheon, associate professor of pathology, University of Pennsylvania School of Medicine, $150, to investigate chemotaxis, especially of leukocytes.

Grant 344: John C. Krantz Jr., professor of pharmacology, University of Maryland School of Medicine, $250, to investigate the alkyl nitrites and their use in angina pectoris.

Grant 345: M. L. Tainter, professor of pharmacology, Stanford University School of Medicine, $250, to investigate sympathomimetic amines.

Grant 346: A. S. Marrazzi, Department of Pharmacology and Therapeutics, New York University College of Medicine, $200, to investigate the actions of epinephrine, ephedrine and other members of the sympathomimetic group on sympathetic ganglions.

Grant 347: Reinhard Beutner, professor of pharmacology Hahnemann Medical College, $80, to investigate the toxicity and detoxification of procaine.

Grant 348: G. O. Broun, professor of internal medicine, St. Louis University School of Medicine, $250, to investigate the prevention and treatment of atherosclerosis.

Grant 349 Garnett Cheney, associate clinical professor of medicine, Stanford University School of Medicine, $250, to investigate vitamin K deficiency in chick hemophilia

Grant 350 James T Culbertson assistant professor of bacteriology, Columbia University College of Physicians and Surgeons, $300, to investigate sulfanilamide

Grant 351 Eugene B Ferris, assistant professor of medicine, University of Cincinnati College of Medicine, $200, to investigate the administration of human serum

Grant 352 Harold D Green, assistant professor of physiology, Western Reserve University School of Medicine, $250, to investigate the effects of drugs on coronary vessels

Grant 353 W F Hamilton, professor pharmacology and physiology, University of Georgia School of Medicine, $125, to investigate vasomotor response of unanesthetized animals

Grant 354 Hebbel Hoff, assistant professor of physiology, Alexander Winkler, instructor in medicine, and Paul K Smith, instructor in pharmacology and toxicology, University of Georgia School of Medicine, $150, to investigate the effect of calcium, magnesium and potassium on the dog heart

Grant 355 Peter K Knoefel, associate professor of pharmacology, University of Louisville School of Medicine, $150 to investigate the action of amines, of the epinephrine series and of related substances on the central nervous system

Grant 356 John B Lagen, research associate in medicine, University of California Medical School $150, to investigate the potassium and sodium ions in the blood of asthmatic patients and in anxiety states

Grant 357 William R Lyons assistant professor of anatomy, University of California Medical School, $250 the standardization of lactogenic hormone

Grant 358 R J Main associate professor of physiology and pharmacology, Medical College of Virginia, $100, to investigate the effects of epinephrine and benzedrine on alveolar carbon dioxide in man

Grant 359 F C McLean, professor of pathology and physiology, University of Chicago $125 to investigate the effects of the growth hormone of the anterior pituitary lobe on the growth of long bones

Grant 360 F C McLean professor of pathology and physiology, University of Chicago, $125, to investigate the mode of action of dihydrotachysterol (A T 10)

Grant 361 S Morgulis professor of biochemistry, University of Nebraska College of Medicine, $100, to investigate the relationship between muscular dystrophy and gonadal atrophy

Grant 362 James M Orten assistant professor of physiologic chemistry, Wayne University College of Medicine, $150, to investigate the effect of copper and certain other inorganic salts on the hypoglycemic activity of insulin

Grant 363 Louis A Toth Department of Physiology, Tulane University of Louisiana School of Medicine, $160, to investigate the influence of low oxygen on urine secretion

Grant 364 Arnold De M Welch Department of Pharmacology, Washington University School of Medicine $300, to investigate the lipotropic action of choline chloride

Grant 365 Harold W Werner assistant professor of physiology and pharmacology, University of North Dakota Medical School $250 to investigate the effects of stimulants on rabbits depressed with ethyl alcohol

Grant 366 George W Piff, Department of Anatomy, Long Island College of Medicine, $75, to investigate the effect of digitalis on the heart

Grant 367 Simon Benson dean of pharmacy, Ferris Institute, $100 to investigate the therapeutic effects of skin counterirritants

Grant 368 Abraham White, Department of Physiological Chemistry, Yale University School of Medicine, $200, to investigate the lactogenic substance isolated in the pituitary

Grant 369 J M Dille Department of Pharmacology, University of Washington College of Pharmacy, $100, to investigate the action of certain depressant drugs

Grant 370 Harald G O Holck, associate professor of pharmacology, University of Nebraska College of Pharmacy $250 to investigate the possible effect of aging on the strength of digitalis preparations

Grant 371 H N Cole, clinical professor of dermatology and syphilology, Western Reserve University School of Medicine $75, to investigate arsphenamine dermatitis

Grant 372 Charles Weiss, associate professor of research medicine, University of California Medical School, $200, to investigate the immunology of staphylococcic infections

Grant 373 Morris Rosenfeld, associate in pharmacology and experimental therapeutics, Johns Hopkins University School of Medicine, $400, to investigate the hormone of the posterior pituitary gland (an ultracentrifugal study)

The following grants were issued before Jan 1, 1938 In some cases the grant has expired and an unexpended balance remains or the work is not yet completed or not yet published

Grant 102 C W Greene, professor of physiology and pharmacology, University of Missouri School of Medicine, $250, to investigate the distribution of nitrous oxide and oxygen in the blood during anesthesia

Grant 119 Nicholas Kopeloff, research associate in bacteriology, New York State Psychiatric Institute and Hospital, $100, to investigate bacillus acidophilus milk for the prevention and treatment of summer diarrhea in babies

Grant 164 E L Jackson, associate professor of pharmacology, Emory University School of Medicine, $200, to investigate the antagonism between sodium barbital and insulin

Grant 201 George R Cowgill, associate professor of physiologic chemistry, Yale University, Sterling Hall of Medicine, $250, to investigate vitamin B in relation to morphine addiction

Grant 221 John G Reinhold, Department of Public Health, Philadelphia General Hospital, $250, to investigate the action of aminoacetic acid (glycine) in progressive muscular dystrophy

Grant 222 Eugene U Still, formerly assistant professor of physiology, University of Chicago, $250, to investigate the changes in the metabolism of the pancreas

Grant 223 Clinton H Thienes, professor of pharmacology, and Lawrence E Detrick, Department of Pharmacology, University of Southern California School of Medicine, $200, to investigate withdrawal phenomena in morphine addicted animals

Grant 232 George R Cowgill, associate professor of physiologic chemistry, Yale University School of Medicine, $250, to investigate the heart in vitamin B deficiency

Grant 236 C W Greene, professor of physiology and pharmacology, University of Missouri School of Medicine, $100, to investigate the pharmacology of the so called specific coronary dilator drugs

Grant 238 Roy R Kracke, professor of pathology, Emory University School of Medicine, $250, to investigate the effect of the oxidation products of aminopyrine and related drugs on the leukocyte counts of rabbits

Grant 248 Fred C Koch, chairman of the Department of Physiological Chemistry and Pharmacology, University of Chicago, $250, to investigate the male sex hormone

Grant 249 J Percy Baumberger, associate professor of physiology, Stanford University Department of Physiology, $200, to investigate the occurrence and oxidation reduction potential of pigments in tumor cells

Grant 251 Bernard Fantus, professor of therapeutics, University of Illinois College of Medicine, $100, to investigate the titration of the antitoxic value of serum of patients who have received tetanus antitoxin

Grant 261 Robert P Walton, professor of pharmacology, University of Mississippi School of Medicine, $100, to investigate the absorption of drugs through the oral mucosa

Grant 263 H A Shoemaker, associate professor of biochemistry and pharmacology, C E Clymer, professor of clinical surgery, and Henry H Turner, University of Oklahoma School of Medicine, $150, to investigate the blood cholesterol and iodine values in thyroid disease and their alteration by treatment

Grant 264 Detlev W Bronk, Johnson professor of biophysics, University of Pennsylvania School of Medicine, $200, to investigate the action of various drugs on the autonomic centers

Grant 270 Elaine P Ralli, assistant professor of medicine New York University College of Medicine, $250, to investigate the effect of carotene on the blood vitamin A

Grant 278 William H Lewis Jr, assistant clinical professor of medicine and Arthur C DeGraff, professor of therapeutics, New York University College of Medicine, $150, to investigate the function of the heart in relation to age

Grant 279 Norman A David, assistant professor of pharmacology, University of Cincinnati College of Medicine, $65, to investigate the effects of carbarsone and other pentavalent arsenicals on the optic nerve

Grant 280 John P Peters, professor of medicine Yale University School of Medicine, $200, to investigate by means of intravenous pyelography the state of ureters and kidneys in a large series of patients after delivery and subsidence of acute signs of toxemia

Grant 281 O W Barlow, formerly assistant professor of pharmacology, Western Reserve University School of Medicine, $125, to investigate circulatory effects of metrazol under conditions of anesthesia with ether as well as under the influence of hypnotics

Grant 282 Arthur W Grace, Department of Medicine, Cornell University Medical College, $250, to investigate the effect of roentgen and Frei vaccine therapy in artificially inoculated venereal lymphogranuloma in guinea pigs

Grant 297 Melvin Dresbach, Harvard University School of Medicine, $250, to investigate the emetic effect of some of the digitalis bodies

Grant 298 Kenneth W Thompson, Department of Physiology, Yale University School of Medicine, $200, to investigate the effects of the thyroid stimulating hormone

Grant 302 Mary E Collett, Flora Stone Mather College, Western Reserve University, $200, to investigate the effect of the female sex hormone on the hot flashes and the basal metabolism of ovariectomized women

Grant 304 Howard B Lewis, professor of biologic chemistry, University of Michigan Medical School, $175, to investigate selenium salts

Grant 305 Beverly Douglas, assistant dean and associate professor of surgery, Vanderbilt University School of Medicine, $250, to investigate the pneumatic (transparent rubber jacket) system of treating extensive wounds

Grant 306 Edwards A Park, professor of pediatrics, Johns Hopkins University School of Medicine, $75 to investigate rickets in the rat and the effect of solution of parathyroid on the circulation of the bone

Grant 307 Ephraim Shorr, assistant professor of medicine, Cornell University Medical College, $200, to investigate methods of determining adequate dosage of corpus luteum hormone for the human being

Grant 308 Claus W Jungeblut, professor of bacteriology, Columbia University College of Physicians and Surgeons, $250, to investigate the relation of vitamin C to diphtheria

Grant 311 Clarence P Berg, assistant professor of biochemistry, State University of Iowa, $250, to investigate amino acids

Grant 313 Treat B Johnson, Sterling professor of chemistry, Yale University, $250, to investigate pyrimidines

Grant 314 F C Koch, chairman Department of Physiological Chemistry and Pharmacology, University of Chicago, $250, to investigate provitamin D

Grant 315 Erwin E Nelson, professor of pharmacology, Tulane University School of Medicine, $125, to investigate some actions of the pituitary

Grant 316: Edward Van Liere, professor of physiology, West Virginia University School of Medicine, $100, to investigate the action of various drugs on gastric motility.

Grant 319: J. P. Quigley, Department of Physiology, Western Reserve University School of Medicine, $250, to investigate gastrointestinal motility.

Grant 324: Howard B. Lewis, professor of biologic chemistry, University of Michigan Medical School, $200, to investigate selenium salts.

Grant 327: Eben J. Carey, dean and professor of anatomy, Marquette University School of Medicine, $250, to investigate the pharmacologic agents that influence the histologic signs of nervous action.

Grant 328: Donald E. Gregg, assistant professor of physiology, Western Reserve University School of Medicine, $250, to investigate the cardiac blood supply in dogs.

Grant 329: Roberta Hafkesbring, associate professor of physiology, Woman's Medical College of Pennsylvania, $250, to investigate the effects of sodium barbital, sodium amytal and pentobarbital sodium on blood pressure, respiration and kidney function.

Grant 332: J. P. Simonds, department of pathology, Northwestern University Medical School, $200, to investigate the selective activity of toxic substances on the kidneys.

Grant 333: Owen S. Gibbs, chief of Pharmacological Division, University of Tennessee College of Medicine, $180, to investigate the toxicity of morphine and scopolamine on rats.

TREASURER'S REPORT

Report of the Treasurer of the American Medical Association for the Year Ending December 31, 1938

Reserve invested as at December 31, 1937	$2,340,373.00	
Bonds Purchased (Cost)	200,812.50	
	$2,541,185.50	
Less:		
Bonds Called	$ 19,575.00	
Bonds Sold	100,406.25	119,981.25
Invested Funds December 31, 1938		$2,421,204.25
Balance for Investment December 31, 1937	$ 39,061.56	
Interest on Investments	87,954.48	
	$ 127,016.04	
Less:		
Transfer to General Fund	$ 83,939.06	
Uninvested Funds December 31, 1938		$ 43,076.98
Invested and Uninvested Reserve as at December 31, 1938		$2,464,281.23

DAVIS MEMORIAL FUND

Balance in Fund December 31, 1937	$7,118.75	
1938 Interest on Bank Balance	107.17	
Total Fund as at December 31, 1938 on Deposit		$ 7,225.92

HERMAN L. KRETSCHMER, Treasurer.

AUDITOR'S REPORT

February 1, 1939.

To the Board of Trustees,
American Medical Association, Chicago, Illinois.

Dear Sirs:

In accordance with your instructions, we have made an examination of the Balance Sheet of the American Medical Association, Chicago, Illinois, as at December 31, 1938, and of the Income Account for the year 1938. In connection therewith, we examined or tested accounting records of the Association and other supporting evidence, and obtained information and explanations from officers and employees of the Association; we also made a general review of the accounting methods and of the operating and income accounts for the year, but we did not make a detailed audit of the transactions. We now submit our report on the examination, together with related statements as enumerated in the index appended hereto.

In our opinion, based on such examination, the accompanying Balance Sheet and related Income Account fairly present the position of the Association as at December 31, 1938, and the results of its operations for the year, subject to the following qualifications and observations:

(1) The inventories of materials, supplies, work in progress and publications, amounting to $92,859.95, are stated in accordance with certificates signed by responsible officials of the Association, and have not been confirmed by us.

(2) In accordance with established practice of the Association, the accounts as stated do not include (a) unrecorded assets in respect of accrued interest on bond investments, and membership dues unpaid; and (b) provision for accrued payroll, accrued property taxes for the year 1938, and sundry unpaid bills.

(3) *Subscriptions paid in advance* are stated at an estimated amount which is based on cash received in December 1938, on account of 1939 subscriptions. This procedure conforms to the method used in prior years.

(4) Advance payments on publications include an estimated amount ($123,745.97) for prepaid subscriptions to Hygeia, and the amount ($12,430.47) received in advance for January 1939, advertising, directory information sales and service.

(5) The buildings of the Association are carried at reproduction values as determined by an appraisal by Holabird and Root as at December 31, 1936, less depreciation accrued to the date of the Balance Sheet. The portion of the depreciation provision for the year applicable to the increase in book value which was recorded at December 31, 1936, as determined by the appraisal, has been charged against the complementary credit included in the Net Worth of the Association in that connection.

(6) No provision has been made in the accounts for possible liability in respect to Federal Social Security Taxes applicable to the period prior to April 28, 1938, amounting to approximately $90,000.00 (including penalties and interest), which liability is contingent upon the outcome of an appeal now pending in the Bureau of Internal Revenue with regard to the status of the Association under the Federal Income Tax Act.

The Association was advised by a letter dated March 4, 1936, from the office of the Commissioner of Internal Revenue, that it was held to be exempt from Federal Income Taxes, under the provisions of Section 101(6) of the Income Tax Act which relates to organizations operated exclusively for religious, charitable, scientific, literary or educational purposes. In a published bulletin issued in January 1937, the Bureau of Internal Revenue ruled that an organization which had been held to be exempt from Federal Income Taxes, under the provisions of Section 101(6) of the Income Tax Act, is also exempt from the taxes imposed under Titles VIII and IX of the Social Security Act. On April 28, 1938, however, the previous ruling (March 4, 1936) regarding the Association's status was supplanted by an advice from the Office of the Commissioner of Internal Revenue to the effect that the basis of exemption should be Section 101(7) of the Income Tax Act, instead of Section 101(6) as previously indicated; the provisions of Section 101(7) relate to organizations classified as business leagues and the like, which are not exempt from Social Security Taxes. The Association has appealed to the Bureau of Internal Revenue for reconsideration of the later ruling (April 28, 1938) and reclassification as a scientific and educational organization.

Pursuant to the ruling of April 28, 1938, the Association was requested by the Treasury Department to file proper returns and pay the taxes required by Titles VIII and IX of the Social Security Act, for the periods from the respective effective dates thereof. The Association, however, has not acceded to this request insofar as the period prior to April 28, 1938, is concerned, but returns have been filed for the period subsequent to that date, as and when due, and the taxes reported therein have been paid under protest.

We have received a letter from Messrs. Loesch, Scofield, Loesch and Burke, attorneys for the Association, regarding litigation pending against the Association or its officers at December 31, 1938, which states that the following lawsuits alleging libel had been filed against the Association or its officers as at December 31, 1938: Dr. Jean Paul Fernel for $1,000,000.00; Robert Wadlow by Harold F. Wadlow for $150,000.00; Hirestra Laboratories, Inc., for $3,000,000.00; Asa Brunson for $250,000.00; William E. Balsinger for $100,000.00; and John R. Brinkley for $250,000.00. In addition to the foregoing suits, the Association is named defendant in certain actions charging conspiracy in restraint of trade. The attorneys state that in their opinion all of these suits will be defeated.

Fidelity insurance is carried against the undermentioned officers and employees, in the amounts stated:

Dr. Olin West, Secretary and General Manager	$10,000.00
Dr. Herman L. Kretschmer, Treasurer	10,000.00
E. A. Hoffman, Cashier	2,000.00
J. E. Hartigan, Assistant Cashier	12,000.00
Sundry Employees (twelve, $1,000.00 each)	
Total Fidelity Insurance	$44,000.00

We have pleasure in reporting that the books are well maintained and that every facility was afforded us for the proper conduct of the examination.

Yours truly, PEAT, MARWICK, MITCHELL & Co.

INDEX TO STATEMENTS

	Exhibit
Balance Sheet, as at December 31, 1938	"A"
Income Account, for the year ended December 31, 1938	"B"
	Schedule
Journal Operating Expenses, for the year ended December 31, 1938	"1"
Association and Miscellaneous Expenses, for the year ended December 31, 1938	"2"

EXHIBIT "A"

BALANCE SHEET AS AT DECEMBER 31, 1938

ASSETS:

Property and Equipment:		
Real Estate—Land at less than cost (see Note "1"); and Buildings at Reproduction Cost New (as appraised by Holabird and Root at December 31, 1936), less Depreciation		$1,146,868.37
Equipment—at Cost, less Depreciation:		
Machinery	$ 127,852.74	
Type and Metal	16,163.69	
Furniture and Equipment	89,882.45	
Chemical Laboratory	8,957.77	242,856.65
Total Property and Equipment		1,389,725.02
Investments—at Cost:		
U. S. Government Securities	1,553,723.06	
Railroad, Municipal and Public Utility Bonds	867,481.19	2,421,204.25
Cash held by Treasurer for Investment		43,076.98
Cash in Bank and on Hand		136,503.86
Accounts Receivable:		
Advertising	63,861.98	
Co-operative Medical Advertising Bureau	12,592.29	
Reprints	3,797.27	
Directory (Estimated)	10,000.00	
Miscellaneous—Deposits, Advances, etc.	15,247.32	105,498.86
Note Receivable		100.00
Inventories of Materials, Supplies, Work in Progress and Publications		92,859.95
Expenditures on Publications in Progress		43,392.23
Prepaid Expenses—Insurance, etc		7,321.25
Total		$4,239,682.40

Note 1: Book value of Land was reduced $40,000.00 as of December 31, 1933, by official action of Board of Trustees. This action was reported to House of Delegates.

LIABILITIES:

Accounts Payable:		
Federal Social Security Taxes (see Note "2")		$ 28,427.78
Co-operative Medical Advertising Bureau		12,092.19
Miscellaneous		5,084.06
		45,604.03
Subscriptions Paid in Advance		165,914.61
Advance Payments on Publications		136,176.44
Net Worth:		
Association Reserve Fund	$ 350,000.00	
Building Reserve Fund	350,000.00	
Retirement Reserve Fund	25,000.00	
Capital Account:		
Amount thereof as at December 31, 1937	$3,135,053.52	
Net Loss for the year ended December 31, 1938	11,401.51	
	$3,123,652.01	
Deduct—Amounts transferred during year to Building Reserve Fund ($50,000.00) and Retirement Reserve Fund ($25,000.00)	75,000.00	3,048,652.01
Increase in book value of Buildings—per appraisal	124,481.59	
Deduct—Depreciation applicable thereto for the years 1937 and 1938	6,146.28	118,335.31
Net Worth, December 31, 1938		3,891,987.32
Total		$4,239,682.40

Note 2: No provision has been made in the accounts for possible liability in respect of Federal Social Security Taxes applicable to the period prior to April 28, 1938, amounting to approximately $90,000.00 (including penalties and interest)—See comment in attached report.

EXHIBIT "B"

INCOME ACCOUNT

FOR THE YEAR ENDED DECEMBER 31, 1938

Miscellaneous Expense—Schedule "2"	290,108.80	748,608.07
Net Loss		$ 11,401.51

Note: No provision has been made in the accounts for possible liability in respect of Federal Social Security Taxes applicable to the period from January 1, 1938, to April 28, 1938, amounting to approximately $20,000.00 (including penalties and interest)—See comment in attached report.

SCHEDULE "1"

JOURNAL OPERATING EXPENSES

FOR THE YEAR ENDED DECEMBER 31, 1938

Wages and Salaries		$ 486,342.28
Editorials, News and Reporting		12,139.56
Paper—Journal Stock		250,163.52
Paper—Miscellaneous		2,090.62
Electrotype and Engravings		15,033.40
Binding		629.86
Ink		9,063.19
Postage—First Class		38,871.82
Postage—Second Class		64,336.09
Journal Commissions		16,204.10
Collection Commissions		620.44
Discounts		30,345.89
Express and Cartage		5,802.48
Exchange		2,450.89
Office Supplies		2,784.43
Telephone and Telegraph		3,620.77
Office Jobbing		15,710.89
Power and Light		10,035.79
Factory Supplies		11,823.80
Repairs and Renewals—Machinery		5,494.48
Miscellaneous Operating Expenses		23,290.55
Bad Debt Losses, and Loss from Sale of Equipment, etc. (Net)		1,775.21
Total Journal Operating Expenses, before Provision for Depreciation		1,008,630.06
Depreciation on Equipment (computed on diminishing Balances):		
Machinery	$6,729.09	
Furniture and Equipment	4,312.29	
Factory Equipment	418.37	
Type	343.41	
Metal	507.31	12,310.47
Total Journal Operating Expenses		$1,020,940.53

SCHEDULE "2"

ASSOCIATION AND MISCELLANEOUS EXPENSES

FOR THE YEAR ENDED DECEMBER 31, 1938

Association Expenses:	
Association	$114,859.42
Health Education	36,892.70
Pharmacy and Chemistry	49,331.41
Chemical Laboratory	24,926.43
Medical Education and Hospitals	77,180.76
Therapeutic Research	7,579.18
Legal Medicine and Legislation	37,670.88
Bureau of Investigation	12,272.06
Bureau of Medical Economics	35,457.50
Council on Foods	22,184.83
Physical Therapy	17,823.33
Council on Industrial Health	7,726.70
Bureau of Association Exhibits	14,122.61
Laboratory Depreciation (5% on diminishing balances)	471.46
Total Association Expenses	$458,499.27
Miscellaneous Expenses:	
Insurance and Taxes	$ 28,778.38
Legal and Investigation	67,096.56
Building Expenses:	32,611.64
Building Depreciation (2.5% on diminishing balances—cost basis)	18,968.18
Fuel	8,361.96
Federal Social Security Taxes (see Note)	30,784.71
Sundry Publications	103,507.37
Total Miscellaneous Expenses	$290,108.80

Note: The above expenses do not include any provision for possible liability in respect of Federal Social Security Taxes applicable to the period from January 1, 1938, to April 28, 1938, amounting to approximately $20,000.00 (including penalties and interest)—See comment in attached report.

REPORT OF THE JUDICIAL COUNCIL

To the Members of the House of Delegates of the American Medical Association:

With the exception of applications for Fellowship in the Association which for one reason or another require investigation by the Judicial Council, the volume of work coming before it has been less than for several years. There has been the usual number of inquiries of an ethical or constitutional nature from individuals and from county and state societies. These inquiries can in general be answered by the Secretary or the Chairman without reference to the entire Council because of official opinions or answers in preceding similar situations. However, all such replies by the Secretary or Chairman receive official approval by the Council at a subsequent meeting.

It is surprising when consideration is given to the vast number and variety of schemes for reducing sickness costs to the low-income population by periodic prepayment plans that the Council has not been asked for an opinion on the ethical features of a single plan. Whether rightly or wrongly, there has been such popularity and enthusiasm for these plans and such haste in their development that the ethical principles involved apparently have been completely ignored. The Council believes it can see a rapidly growing menace to many of the sound principles which have governed the practice of medicine by the members of this organization for many years and which have contributed in preponderant measure to the high quality of medical care which the people of this country as a whole enjoy. In this report the Council desires only to sound a warning and a caution and to call attention to the fact that the practice of medicine by the members of this organization is governed, so far as ethical considerations are concerned, by the Principles of Medical Ethics as approved and adopted by the House of Delegates, which will remain as they are until the House itself changes or eliminates them. The function of the Judicial Council is interpretation only.

But one appeal from a disciplinary action by a constituent association has been brought before the Judicial Council this past year. This appeal was heard recently. The briefs and arguments are under consideration and study by the individual members of the Council. No decision has been reached as yet.

TEACHING IN SCHOOLS OF CHIROPODY OR PODIATRY

At the last annual meeting of the House of Delegates, in San Francisco, a resolution was introduced declaring that the serving of members of the American Medical Association on the faculties of schools of chiropody is unethical. The cause of the introduction of the resolution was a statement made in the annual report of the Judicial Council for that year that "teaching in cultist schools and addressing cultist societies is even more reprehensible" than association with cultists in practice. The resolution was referred to the Judicial Council as a reference committee and on its recommendation the resolution was laid on the table. Since that meeting the Council has investigated the matter further and is of the opinion that the practice of chiropody is not a cult practice as is osteopathy, chiropractic or Christian science, which have bases of treatment not supported by scientific or demonstrated knowledge but on which bases all diseases are treated. Chiropody is rather a practice ancillary—a hand maiden—to medical practice in a limited field considered not important enough for a doctor of medicine to attend and therefore too often is neglected. General opinion seems to be that chiropody fairly well satisfies a gap in medical care that the profession has failed to fill. There are several reputable medical colleges whose faculties teach this branch of the healing art to students who later become chiropodists and the Council can see no reason to declare such teaching by members of this organization to be unethical, provided the schools in which they teach are connected with approved schools of medicine and recognized standards of premedical education are required.

DIAGNOSTIC CLINICS

The Judicial Council has been asked to give a definition of a "diagnostic clinic." The word clinic is a very popular one in medical practice today and may mean anything from one doctor practicing medicine with lay assistants to a most elaborate organization prepared to do anything of a medical nature. There are also many types of clinics the names of which describe the type of work done in them. The Greek basis of the word "clinic" meant simply medical instruction at the bedside of patients. The term has never been copyrighted and any one may use it and put his own interpretation on its meaning. The name "clinic," because of its association with the earlier users of the term, now in the lay mind implies a very superior service by very superior individuals, which too frequently is not the case. If the American Medical Association is to define a diagnostic clinic it must be done in a way that will represent the efficiency that modern scientific progress has made possible to the doctor of medicine who has kept abreast of that progress, and the idealism or ethical principles that for hundreds of years have been our most cherished heritage as a profession. It must not be a definition which any charlatan be he medical or lay, can point to as describing himself. It must be a definition which is definite. Obviously such a definition cannot be made in a sentence and equally obvious is the fact that those most anxious to use the designation will be the least pleased with it. The Council has given careful consideration to the problem of what a real diagnostic clinic is and what it should be and has sought advice from sources held in high esteem. It submits the following as its opinion of a proper definition of a diagnostic clinic worthy of the name:

1. A diagnostic clinic is an organization of physicians whose sole work in the clinic is to make or supervise diagnostic examinations of patients referred to the clinic by doctors of medicine, or to collaborate in general diagnostic surveys.

2. The reports of the diagnostic clinic on examinations and tests are made only to the referring physician unless he requests that the case and the recommendations for treatment be discussed with the patient as part of a professional consultation at which the relationship of the results of the diagnostic studies to the general condition of the patient is open for discussion. In such case, discussion is only by a member of the staff.

3. The staff of the diagnostic clinic should include representatives from all the specialties that are of recognized diagnostic usefulness. Every clinical examination, laboratory test or x-ray procedure is made by a physician who specializes in that field or under his supervision. The clinic must be equipped to allow the various specialists to exercise fully their abilities.

4. The control of the clinic must be vested in one or more members of the professional staff. Any profits are to be apportioned only to the members of the staff actually engaged in the work of the clinic. There must be no dividends, bonuses or salaries paid any individual except for services rendered.

5. The clinic must be governed in its activities by the same ethical principles as apply to an individual member of the American Medical Association.

It is recognized that under this definition only in cities large enough to support the various specialists needed can a diagnostic clinic be established or maintained. Unless the specialists are available it is not a diagnostic clinic worthy of the name.

Respectfully submitted.

GEORGE EDWARD FOLLANSBEE, Chairman.
EDWARD R. CUNNIFFE.
WALTER F. DONALDSON.
JOHN W. BURNS.
JOHN H. O'SHEA.

REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

To the Members of the House of Delegates of the American Medical Association:

1. In connection with the survey of undergraduate medical schools the following institutions have been revisited:

University of Arkansas School of Medicine
Boston University School of Medicine
Wayne University College of Medicine
Albany Medical College
Wake Forest College School of Medical Sciences
Woman's Medical College of Pennsylvania
Medical College of the State of South Carolina
Meharry Medical College
University of Tennessee College of Medicine

Reports indicating progress have been received from:

University of Maryland School of Medicine and College of Physicians and Surgeons
University of Missouri School of Medicine
University of North Carolina School of Medicine
Hahnemann Medical College and Hospital of Philadelphia
Medical College of the State of South Carolina

2. The Council's report of the survey is being prepared and will be ready for publication, it is hoped, by the end of the summer.

3. Graduate education, for purposes of study, has been considered under three categories: first, systematic courses of instruction conforming to generally accepted academic standards; second, apprenticeship courses, consisting of residencies and fellowships, and, third, extension courses, conducted either separately or jointly by universities and medical societies. A preliminary report on this phase of graduate medical education was published in August 1938. The complete report will be issued when all the states have been visited.

4. From Feb. 1, 1938, to Jan. 31, 1939, 375 hospitals were visited, as follows:

For approval of internships	207
For approval of residencies	88
For approval of both	52
For registration	28

5. The report of the Interdepartmental Committee to Coordinate Health and Welfare Activities proposed among other things a vast increase in the hospital facilities of the United States. The evidence which the committee submitted in support of its program was so untrustworthy that the Council felt compelled to prepare and circulate a pamphlet showing the exact distribution of hospital facilities in the United States.

6. The Council has also made a careful study of existing hospital facilities in a single state—Mississippi—a report of which will be presented to the House of Delegates at St. Louis.

7. In addition to the visitation of hospitals, inspections were made of technical schools as follows:

Laboratory technic	25
Physical therapy	6
Occupational therapy	1

8. The Council, during 1938, was represented at the following meetings:

American Medical Association, San Francisco
American Medical Association, Conference on Industrial Health, Chicago
American Hospital Association, Dallas, Texas
Catholic Hospital Association, Buffalo
Association of American Medical Colleges, Syracuse, N. Y.
American Congress of Physical Therapy, Chicago
American Society of Pharmacology and Experimental Therapeutics, Baltimore
American Society of Tropical Medicine, Oklahoma City
Federation of American Societies for Experimental Biology, Baltimore
Southern Medical Association, Oklahoma City
History of Science Society, Chicago
Northwest Regional Conference, Chicago
Tri State Hospital Association, Chicago
American Congress of Physical Therapy, Western Section, Los Angeles
Illinois Society of Experimental Biology and Medicine, Chicago
Minnesota Hospital Convention, St. Paul
Michigan Hospital Association
Postgraduate Course on Industrial Hygiene, Allegheny County Medical Society, Pittsburgh
Multnomah County Society, Portland, Ore.
Hospital staff meetings, twenty three
Installation of president of Tulane University, Vanderbilt University and Tufts College

9. Exhibits were prepared for:

World's fairs, New York and San Francisco
San Francisco and St. Louis meetings, American Medical Association
American Hospital Association
Catholic Hospital Association

10. Publications:

Hospital Number of THE JOURNAL
State Board Number of THE JOURNAL
Educational Number of THE JOURNAL
Study of Hospital Facilities in the United States
Study of Graduate Medical Education
Approved Colleges of Arts and Sciences and Junior Colleges
Choice of a Medical School
Data for fifteenth edition of American Medical Directory on medical schools, special examining boards and hospitals
Proceedings of Annual Congress
Essentials

11. Owing to the pressure of extra work created by the National Health Conference last July and by the indictment of the Association by a grand jury of the District of Columbia, the Council is not yet in a position to make a complete report on medical practice in hospitals in accordance with the instructions of the House of Delegates (THE JOURNAL, July 2, 1938, p. 45), but an agreement has been reached with a representative group of radiologists as to the definition of the function of the radiologist in the hospital. This definition is incorporated in the revised Essentials of a Registered Hospital, submitted herewith for approval.

12. At the Congress on Medical Education and Licensure, the registration this year was 550, indicating a larger attendance than at any time within the last ten years.

13. Through the Social Security Act, the federal government has made available several million dollars for the further training of physicians. A number of state societies have found it possible, through the cooperation of the state department of health, to direct the expenditure of this money and to strengthen their own programs of postgraduate education. In other states the health department has inaugurated independent courses with results not altogether satisfactory. The House of Delegates might well bring to the attention of each of the constituent societies of the Association the paramount importance of retaining control of this phase of professional education.

14. At the Council's meeting of Feb. 11, 1939, a committee consisting of Dr. Willard C. Rappleye, Dr. Robin C. Buerki and Dr. J. W. Bowers presented to the Council an invitation to participate in the formation of an "Advisory Council on Medical Education, Licensure and Hospitals," an organization initiated by representatives of some eight or ten associations more or less interested in the subjects named in the title. This invitation reads:

> This Council is created to meet the need of a body representing the medical profession, the universities, medical schools, hospitals, licensing bodies, specialty boards, public health agencies and other national organizations in this country which deal with different phases of medical education. The Council shall serve as a clearing house for the cooperative consideration of those problems and programs of professional training with which more than one organization is concerned, and shall serve as a medium for consultation and mutual assistance in the formulation and support of adequate educational standards, and as an agency for advice and recommendations to member and other organizations dealing with medical education.

The Council, feeling itself incompetent to act on this matter without instructions from the House of Delegates, voted:

> That the Council recommend to the House of Delegates that it be authorized to appoint from its body three representatives to act on this Advisory Council on Medical Education, Licensure and Hospitals without voting power.

15. The Council submits herewith for the approval of the House of Delegates:

(*a*) Revised "Essentials of a Registered Hospital"
(*b*) Revised "Essentials of Approved Residencies and Fellowships"
(*c*) Revised "Essentials for Approved Examining Boards in Specialties"

Respectfully submitted.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS.
RAY LYMAN WILBUR, Chairman.
J. H. MUSSER.
FRED MOORE.
REGINALD FITZ.
FRED W. RANKIN.
CHARLES GORDON HEYD.
FRANK H. LAHEY.
WILLIAM D. CUTTER, Secretary.

Essentials of a Registered Hospital

General Statement.—The American Medical Association gives recognition to hospitals by admitting to the Hospital Register those that are found to qualify according to the essentials contained in the following paragraphs.

Registration is a basic distinction between all recognized hospitals and those that are refused recognition. It is a prerequisite to the consideration of a hospital for approval for interns or for residencies in specialties.

The registration of hospitals, the approval of hospitals for interns, approval for residencies in specialties, and all other service of the Association regarding hospitals is carried on by the Council on Medical Education and Hospitals.

It is the desire of the Council to cooperate in every way for the improvement of hospital service, whereby the sick and injured may be provided with scientific and ethical medical care.

The Council does not have nor does it assume legal authority over any hospital. It recognizes clearly that the officers in charge of such institutions have the unquestioned right to conduct the hospitals in any way they may deem wise. If a hospital desires to have its name appear on the American Medical Association Hospital Register and thus have the endorsement of that Association, it should be willing to comply with the principles which the Council on Medical Education and Hospitals considers necessary.

Essentials of a Registered Hospital.—Hospitals seeking admission to the register should have the following qualifications:

1. *Organization.*—The organization should consist of a board of trustees or other supreme governing body having final authority and responsibility and an executive officer or superintendent to carry out the policies adopted by the governing body. The executive officer should be assisted by adequate competent personnel.

Regardless of the form of organization, the hospital should function primarily in the interests of the sick and injured of the community.

2. *Staff.*—This constitutes the most important essential. The staff should be organized and composed of regular physicians who are properly qualified as to training, licensure and ethical standing.

Staff membership and the use of the hospital's facilities must be limited to doctors in medicine. Where cult practitioners, osteopaths, chiropractors or other healers outside the scope of regular medicine are allowed to use the hospital's diagnostic facilities, to prescribe for or treat patients in the hospital, or to enter orders or other data on the case records, such a hospital obviously cannot be recognized or endorsed by the American Medical Association.

Regular staff conferences should be held at least monthly and preferably more often. All deaths that occur during the period intervening between meetings, perplexing cases, and patients who do not respond to treatment should be discussed. When postmortem examinations have been performed there should be a presentation of the clinical aspect of the patient and the postmortem observations. Interesting pathologic specimens from surgery or removed at postmortem should be presented and discussed with regard to the preoperative or antemortem findings.

Minutes of staff conferences should be kept and filed with the hospital records. The activity of the staff as to scientific meetings and clinical and pathologic conferences is an index to the scientific mindedness and progressiveness of the group.

3. *Nurses.*—A competent nursing staff should be provided by employing an adequate number of registered nurses who are graduates of schools of nursing recognized by the state board of nurse examiners, or by maintaining such a school.

All nursing should be supervised by qualified registered graduates.

4. *Records.*—An adequate record system should be maintained. No particular system or set of forms is recommended, since requirements are not the same under varying circumstances. The average case record should include at least a brief medical history, physical examination, laboratory reports, diagnosis, operative record, progress notes, nurses' notes and summary. Case records should be complete in every department and reviewed and signed by the attending physicians before they are placed in the permanent file. Roentgenologic interpretations, pathologic descriptions and diagnoses of tissues removed in the operating room, and (when an autopsy has been performed) a description of postmortem observations, should be included with the patient's record.

Case histories and physical examinations should be recorded in the patient's chart within twenty-four hours after the patient has been admitted to the hospital. A patient should not be operated on, except in the case of emergency, when the history, physical examination and routine laboratory work have not been completely recorded in the chart. The duty of recording these data falls on the attending physician and he should be held directly responsible for the case records.

Monthly and annual analyses of hospital service should be made in order that the staff may be in a position to improve its service.

5. *Pharmacy.*—The handling of drugs should be adequately supervised and should comply with state laws.

6. *Pathology.*—The hospital should provide or have ready access to laboratory facilities in accordance with its needs. All tissues removed in the operating room should be examined, described and diagnosed by a competent pathologist excepting tissues, such as tonsils and teeth, in which the pathologic changes are quite obvious.

A physician-pathologist qualified by training and experience to supervise the laboratory service and interpret tissue pathology should be employed on a full time or part time basis. When this is not practicable, arrangements should be made with a consulting pathologist for tissue diagnosis, postmortem work and the interpretation of the more complicated tests and determinations in clinical and surgical pathology, as well as in general clinical laboratory work. Preferably the pathologist should be a physician who holds a certificate of the American Board of Pathology.

Autopsies.—Every effort should be made to secure consent for autopsies, which should be performed by a competent pathologist.

7. *Radiology.*—The responsibility for all radiologic examinations must rest on the physician-roentgenologist who is head of the department. His findings and conclusions for all examinations should be placed in the patient's chart. Nothing in this provision should preclude additional study and interpretation by qualified attending physicians on the staff.

The physician-roentgenologist should be preferably one who is a diplomate of the American Board of Radiology or a physician whose qualifications are acceptable to the Council on Medical Education and Hospitals of the American Medical Association.

It shall not be the policy of the hospital to make a profit from the department of radiology.

8. *Ethics.*—In order that a hospital may be eligible for registration it will, of course, be expected that the staff and management conform to the principles of medical ethics of the American Medical Association with regard to advertising, commissions, division of fees, secret remedies, extravagant claims, overcommercialization and in all other respects.

Essentials of Approved Residencies and Fellowships

Residencies and fellowships in the clinical branches of medicine and surgery, pathology and radiology represent advanced training usually in preparation for the practice of a specialty. Residencies in specialties, as defined by the Council, are straight services of one or more years following an approved internship. A fellowship is a form of apprenticeship which in some cases is indistinguishable from a residency, although it usually offers greater opportunity for the study of basic sciences and research. Ordinarily a fellowship is a university rather than a hospital appointment. *Mixed residencies* are general hospital assignments following internship. (They include services classified as general residencies and chief residencies.)

Approved residencies and fellowships are offered in the following branches of medicine:

1. Anesthesiology
2. Cardiology
3. Communicable Diseases
4. Dermatology and Syphilology
5. Epilepsy
6. Fractures
7. Gynecology
8. Malignant Diseases
9. Medicine
10. Mental Deficiencies
11. Mixed Residency
12. Neurology
13. Neurosurgery
14. Obstetrics
15. Obstetrics-Gynecology
16. Ophthalmology
17. Ophthalmology-Otolaryngology
18. Orthopedic Surgery
19. Otolaryngology
20. Pathology
21. Pediatrics
22. Physical Therapy
23. Plastic Surgery
24. Psychiatry
25. Radiology
26. Surgery
27. Thoracic Surgery
28. Traumatic Surgery
29. Tuberculosis
30. Urology

I. GENERAL REQUIREMENTS

Registration.—Previous admission to the Register of the American Medical Association is essential in the case of hospitals offering fellowships and residencies in specialties.

This implies that each hospital must be adequately organized, staffed and equipped and that it be conducted primarily for the welfare of the sick. The educational function described in these Essentials is supplementary to the main purpose of the hospital service but is closely related thereto in that it serves to improve the quality of medical practice.

Size.—The size of the institution is not a primary consideration. The clinical material, however, should be sufficient to enable residents and fellows to observe the principal manifestations of the disease, or diseases, they are studying.

Plant and Equipment.—The physical plant should be such as to assure the safety and comfort of the patients. There should be such equipment, appliances and apparatus as are commonly employed in the specialty in which training is offered and in the use of which the resident should become proficient.

II. STAFF

There must be an organized staff of ethical, licensed physicians holding the degree of doctor of medicine from acceptable medical schools. The particular specialties in which residents are being trained must be represented on the staff by well qualified, experienced and proficient physicians.

In general hospitals, the staff shall further provide a definite departmental organization in those branches of medicine in which residencies are offered. The director of each service should be a competent specialist who is at least eligible for certification by the corresponding specialty board. He should assume direct responsibility for the training of residents and fellows and should stimulate others of his staff to give instruction and sympathetic cooperation which graduate students require.

It is essential that there shall be at least monthly clinical-pathologic conferences or other regular staff meetings at which histories and clinical observations in selected cases may be reviewed, particularly when the death of patients has necessitated special study including necropsy performance. In addition to meetings of the staff as a whole, it is expected that departmental conferences shall be conducted in which residents may take an active part to the end that the character of the service given by that department to its patients may be recurringly evaluated. Other educational activities requiring the full support of the staff are described under Training Program, section IX.

III. DEPARTMENT OF RADIOLOGY

The department of radiology shall be under the direction of a qualified radiologist proficient in the various functions of his specialty. He must likewise cooperate in all matters pertaining to residencies and fellowships which fall within the scope of his service. The department should contain roentgenographic, roentgenoscopic and, where required, therapeutic equipment and radium. All these facilities are essential in institutions offering a complete residency or fellowship program in radiology.

After Jan. 1, 1942, an applicant for certification by the American Board must have completed a period of study after the internship of at least three years in a recognized institution or radiologic department. This period of specialized training should include an active experience in radiology of not less than twenty-four months and graduate instruction in pathologic anatomy, radiophysics and radiobiology. Board certificates are offered in (1) the entire field of radiology, (2) roentgenology, (3) diagnostic roentgenology and (4) therapeutic radiology.

Residencies and fellowships of from one to three years' duration should be organized in such a manner that on completion of the graduate program the aggregate of training will coincide with the foregoing requirements. Courses of shorter duration, however, may provide the basic instruction in radiology required by other specialties. A complete residency or fellowship program supplies training in all divisions of the specialty—diagnostic roentgenology, therapeutic roentgenology and radium therapy. Without attempting to define a detailed plan of instruction it can be suggested that the first year be devoted principally to pathology, roentgenologic technic and a general orientation in the radiologic field. In the second and third years the clinical applications of radiology should be emphasized with at least six months assigned exclusively to radiotherapy. In view of the importance of pathology as a basis for radiologic diagnosis and therapy it is recommended that a minimum of six months be devoted to pathologic anatomy, particularly the study of gross pathology and tumors. Instruction in radiophysics and radiobiology may well run concurrently with the training in radium therapy and therapeutic roentgenology.

Residencies in a restricted field of radiology can likewise be modeled on this plan. The training should be systematic and progressive in character with gradual assignment of responsibility in both diagnosis and therapy. It should also include an active participation in radiologic conferences, staff meetings, and joint conferences with other departments. An adequate amount of clinical material must be available in the divisions of radiology in which residency or fellowship training is offered.

IV. DEPARTMENT OF PATHOLOGY

The department of pathology must be under the supervision of a qualified pathologist who shall be prepared to cooperate fully in the training of graduate students and supervise any direct contact which they have with the laboratory. The department should provide apparatus, reagents and materials necessary to the operation of a modern clinical and pathologic laboratory. Adequate necropsy facilities should also be available.

Residencies and fellowships, in contrast to the shorter courses for basic instruction in pathology, are ordinarily of from one to three years' duration. Thus they may serve to fulfil the requirements for certification, which specify in addition to the internship a period of study of at least three calendar years, including one year in the various phases of clinical pathology and not less than two years of training and experience in a department of pathologic anatomy. (The training may be combined or in sequence.)

The teaching material must be sufficient in kind and amount to afford graduate students adequate training in all divisions of the service and in both gross and microscopic pathology. Systematic instruction should be carried out with the use of fresh material and collections of slides and museum specimens for comparative studies in histology and pathology. As the training continues an increasing amount of responsibility should be assigned to the residents and fellows in tissue diagnosis, in actual performance of postmortem examinations and in the preparation of pathologic reports and necropsy protocols. Further instruction should be obtained through active participation in clinical-pathologic conferences, staff meetings and joint conferences with other departments.

V. NECROPSIES

Thoroughness in postmortem performance should be emphasized. All institutions and individual clinical services desiring approval for the training of residents or fellows must examine post mortem 15 per cent or more of their fatal cases. An additional requirement of at least 100 necropsies a year applies to institutions offering residencies or fellowships in pathology. Complete necropsy records should be kept on file and each should contain a summary of the clinical record and a detailed description of both the gross and the microscopic observations. Graduate students of all departments should attend postmortem examinations as often as possible. They may, with value, participate in the performance of necropsies from their own service and in the preparation of the protocols.

VI. MEDICAL LIBRARY

Institutions offering graduate training should maintain or provide ready access to an adequate medical library containing modern texts, the QUARTERLY CUMULATIVE INDEX MEDICUS and current journals relating to the fields in which residencies and fellowships are offered.

VII. HISTORIES AND RECORDS

There must be complete histories giving the patient's complaint, physical examination at time of admission, preliminary diagnosis, laboratory observations, descriptions of operations if any, regular progress notes, final diagnosis, condition on discharge, end results and, in case of death, necropsy observations if postmortem examination is performed.

The histories should show by signatures, or initials, all persons writing them or parts of them as well as the staff members by whom the histories are verified. Likewise, all orders and progress notes should be initialed or signed.

The records should be in charge of some competent person, preferably a trained record librarian. Alphabetical and diagnostic indexes of the patients should be maintained and the records filed so as to be readily accessible from either source. Operative procedures and radiologic and pathologic material should likewise be classified in a suitable manner.

VIII. ELIGIBILITY OF APPLICANTS

Candidates for residencies or fellowships should be selected from graduates of approved medical schools, who have served an internship in an approved hospital or have had two or more years in practice. It is recommended, however, that candidates seeking residencies or fellowships in such specialties as urology, orthopedics, plastic surgery, thoracic surgery and neurosurgery should have completed one year of general surgical training in addition to the internship.

IX. TRAINING PROGRAM

Residencies and fellowships are designed primarily to meet the requirements for certification of special practice. Individually they may not fulfil all the essentials of a specialty board, but each service that is properly organized will make a substantial contribution to the graduate program. In all instances the term of service should be at least twelve months and might well be extended to two or more years when suitable facilities are available. An affiliation with a university or medical school is desirable to provide the required training in basic sciences relating to individual specialties.

Aside from the daily contact with patients and staff men, the assumption of responsibility is the most valuable aspect of residency and fellowship training. Consequently, as ability is demonstrated, an increasing amount of reliance should be placed in the judgment of graduate students both in diagnosis and in treatment.

Residents and fellows should be given an opportunity to contribute to the effectiveness of the hospital service by some investigative work. This may take the form of research in the hospital laboratories or wards, summaries of medical literature, or the preparation of statistical analyses derived from the hospital record department. The members of the resident staff should likewise be encouraged to engage in teaching activities, particularly in relation to the training of medical students, interns and nurses.

The effectiveness of a residency or fellowship program depends largely on the quality of medical supervision and teaching. It is important, therefore, that methods of instruction be employed which are best suited to the special field. Emphasis should be placed on bedside instruction, teaching rounds, departmental meetings or seminars, clinical-pathologic conferences, demonstrations and lectures. The review of medical literature is an essential feature of residency training. Likewise the study of basic sciences as required by specialty boards should be integrated with the clinical experience. In the operative divisions it is desirable that facilities be available for anatomic dissection and experimental surgery on animals or on the cadaver. Additional requirements apply to graduate courses leading to advanced degrees.

The following regulations pertaining to individual specialties contain a brief abstract of the special training required for certification by the Specialty Boards. The full requirements for certification should be ascertained by direct correspondence with the secretary of each board as listed in section XI.

1. ANESTHESIOLOGY.—Present requirements for certification by the American Board include an internship of one year and at least four calendar years of active experience limited to anesthesiology. This period of specialized training and practice should include a minimum of two years of supervised clinical instruction in anesthesiology and graduate study in the related basic sciences, particularly anatomy, physiology, pharmacology and biochemistry. After Jan. 1, 1942, the requirements will be interpreted as three years of special training and three years of additional practice in anesthesiology.

The director of the department should be a qualified physician limiting his practice to anesthesiology. It is preferable that he serve on a full time basis to supervise the technical and educational activities of the department. His staff must include an adequate number of trained anesthetists in accordance with the needs of the service.

Equipment must be satisfactory for the teaching of modern methods of anesthesia and should include suitable apparatus for gas administration, resuscitation and inhalation therapy. Likewise, the clinical material must be sufficient to afford graduate students adequate experience in the various methods and types of anesthesia now commonly employed. It is expected that each graduate student should administer a minimum of 500 anesthetics a year, of which 400 should be general surgical in type. Residencies and fellowships organized in accordance with the foregoing requirements should provide systematic clinical and technical instruction supplemented by seminars, lectures and demonstrations on anatomic and other material.

2. CARDIOLOGY.—(See Medicine.)

3. COMMUNICABLE DISEASES.—(See Medicine.)

4. DERMATOLOGY AND SYPHILOLOGY.—In order to qualify for certification in dermatology and syphilology, graduate students who begin their training after Jan. 1, 1940, must complete three years of systematic instruction and two additional years of study or practice. The period of specialized training following internship shall include (*a*) not less than eighteen months of active experience in clinical dermatology and syphilology and (*b*) graduate study in the basic sciences of embryology, histology, chemistry, physiology, bacteriology, mycology, parasitology, pathology, immunology, serology, pharmacology and physics as related to physical therapy.

Residencies and fellowships designed to meet these requirements should provide an organized course of instruction involving lectures, seminars, clinical demonstrations and laboratory assignments especially in histopathology, parasitology, mycology and immunology. To facilitate clinical and laboratory teaching it is essential that the department have ready access to an adequate supply of classified anatomic and pathologic material including histologic and lantern slides for demonstrations. Projection apparatus should be available and also facilities for clinical photography.

Since the practice of dermatology and syphilology is concerned largely with ambulatory patients, it is essential that an active outpatient service be available to furnish sufficient clinical material in the various subdivisions of the specialty. It is also desirable that hospital facilities be available and that graduate students be given an opportunity to observe the dermatologic manifestations of the acute contagious diseases. Ordinarily a minimum of 3,500 annual visits is considered essential in the dermatologic division and a similar number in syphilology.

5. EPILEPSY.—(See Psychiatry and Neurology.)

6. FRACTURES.—(See Surgery; also Orthopedics.)

7. GYNECOLOGY.—(See Obstetrics and Gynecology.)

8. MALIGNANT DISEASES.—The division of malignant diseases is largely a combination of services involving practically all the branches of medicine and surgery, including pathology and radiology. It is important, therefore, that competent staff physicians be assigned to all departments and that special facilities be available for histopathology, diagnostic roentgenology, operative surgery, therapeutic roentgenology and radium therapy.

The clinical material should be sufficient in kind and amount to enable graduate students to observe and study the various types of malignant diseases and the methods of therapy commonly employed. A teaching service should have approximately 350 inpatients a year and additional material in the outpatient tumor clinic.

Ordinarily, the training is general in type with assignments in clinical diagnosis, pathology, diagnostic roentgenology, surgery, therapeutic roentgenology and radium therapy. Courses in surgical and postmortem pathology, radiophysics and radiobiology are often included. In some instances the service is limited in scope and is utilized primarily as supplementary training in internal medicine, surgery, pathology, radiology or other specialties.

9. MEDICINE.—Requirements for certification in this specialty include an approved internship of at least twelve months, three years of special training and two additional years of practice in the field of internal medicine or its more restricted and specialized branches. The graduate training should include several months of properly supervised instruction in anatomy, physiology, biochemistry, pathology, bacteriology or pharmacology as related to medical specialties.

Residencies and fellowships should necessarily be organized on a broad basis to furnish instruction in the various specialties which combine to form the foundation of practice in internal medicine. Accordingly, the service should not be limited entirely to general medicine and its subdivisions of allergy, cardiology, gastro-enterology, metabolic diseases, contagion and tuberculosis but might well include a reasonable amount of instruction in the divisions of psychiatry and neurology, dermatology and syphilology, and pediatrics, now organized as independent specialties.

It should be taken into account, however, that not more than one year of instruction in the related medical specialties and basic sciences can be applied to the three year period of special training.

In institutions offering residencies and fellowships in general medicine, cardiology, communicable diseases or tuberculosis, emphasis should be placed on the educational features of the service and residents should receive regular instruction from members of the staff in methods of clinical study and diagnostic and therapeutic procedures. Of particular importance is the study of etiology, pathogenesis, symptomatology and course of the various diseases so that the residents may develop skill and accuracy in diagnosis as well as a mature judgment and resourcefulness in therapy.

Under the supervision of qualified members of the staff the residents should assume individual responsibility in actual case management. They should also be required to correlate clinical studies with postmortem pathology, review medical literature and take an active part in weekly teaching rounds, departmental seminars and clinical-pathologic conferences. Instruction in the basic sciences may well be integrated with the clinical experience.

Training in tuberculosis should be of such a character that residents may become thoroughly familiar with the various phases of institutional service as well as the community aspects of tuberculosis control. This necessitates a well organized program of instruction with rotating assignments in the admitting department, infirmaries, convalescent and ambulatory wards and the outpatient clinics. Careful instruction should be provided in diagnosis, interpretation of roentgenograms, therapeutic procedures and general sanatorium care. It is particularly important that the residents become fully acquainted with the use of pneumothorax therapy and the technic of the initial induction as well as the subsequent refills. If a surgical department is maintained, the operative service may be combined with the general training in tuberculosis or it may form the basis of a separate residency in thoracic surgery.

It must be emphasized that residencies in tuberculosis are educational in character and that of the full time sanatorium staff only those physicians who serve primarily on an educational basis come within the residency classification of the Council.

The clinical material must be adequate in kind and amount. In general medicine a minimum of 400 annual admissions is considered desirable, while in tuberculosis approximately 125 inpatients a year may be sufficient.

Residencies in cardiology and communicable diseases may well follow the general plan indicated. In cardiology a large part of the required teaching material is frequently supplied on a consultation basis and therefore the number of patients admitted directly to the department may not be an accurate index of the scope of the service. A well balanced service is essential for residency training in contagious diseases. Between 300 and 400 admissions a year may be considered sufficient, especially if most of the acute contagious diseases are well represented.

10. MENTAL DEFICIENCIES.—(See Psychiatry and Neurology.)

11. MIXED RESIDENCY (see definition in opening paragraph).—All hospitals approved for intern training are automatically accredited for mixed residencies which represent general assignments of at least one year duration following an approved internship. Other hospitals presenting a general service and an admission rate of at least 1,500 patients a year may likewise be certified if they conform to the general requirements for residency training.

12. NEUROLOGY.—(See Psychiatry and Neurology.)

13. NEUROSURGERY.—(See Surgery; also Psychiatry and Neurology.)

14. OBSTETRICS.—(See Obstetrics and Gynecology.)

15. OBSTETRICS AND GYNECOLOGY.—Candidates for certification in obstetrics and/or gynecology must in addition to other requirements have completed a year of internship and five years of practice including at least three years of special training in obstetrics and/or gynecology. After Jan. 1, 1942, the requirements for all candidates will consist of one year of approved internship followed by a minimum of seven years of practice including not less than three years of special training in obstetrics and/or gynecology.

Institutions offering residencies or fellowships in obstetrics and/or gynecology must provide surgical and obstetric facilities adequate for the clinical and teaching needs of the service. They should also furnish sufficient teaching material to afford graduate students a wide experience in clinical diagnosis, treatment, and technical and operative procedures. Ordinarily an admission rate of 400 patients a year is considered necessary for graduate training in obstetrics and a similar requirement applies to gynecology. In a combined service each division should furnish a corresponding amount of clinical material. Antepartum and follow-up clinics are also essential.

The graduate program should include the study of fundamental subjects, particularly obstetric and gynecologic pathology, anatomy, embryology and physiology. Primarily, however, the emphasis should be placed on clinical training in order that graduate students may receive ample instruction in the various phases of gynecologic and obstetric service—antepartum care, treatment of toxemias of pregnancy, management of normal and abnormal labor, technic of versions, breech extractions and instrumental delivery; diagnosis and treatment of the complications of labor, postpartum hemorrhage, puerperal infections; operative obstetrics and gynecology. Courses of instruction should include assignments in pathology, demonstrations on the manikin, departmental seminars, clinical-pathologic conferences, and teaching rounds. Training in surgical technic should be sufficient to enable residents and fellows to undertake operative work on their own responsibility especially toward the end of the graduate program.

16. OPHTHALMOLOGY.—To become certified in ophthalmology a candidate must have completed an internship of one year or its equivalent and a period of combined study, training and practice of not less than three years. The special training should include active clinical experience and graduate study of related basic sciences, particularly anatomy, histology, embryology, optics, physiologic optics, visual physiology and psychology, pathology, bacteriology and pharmacology. The candidate should have knowledge of the application of these subjects and their use in clinical ophthalmology especially in refraction, disorders of motility and binocular vision, perimetry, and in the use of the ophthalmoscope, retinoscope and slit lamp.

Residencies and fellowships should be organized in such a manner that on completion of the graduate program the aggregate of training should coincide with the foregoing requirements. There must be adequate equipment for diagnosis, therapy, refraction, operative procedures, and preferably additional facilities for dissection and experimental surgery. Histologic and pathologic material should be available for demonstration and individual study. The clinical facilities must be sufficient in kind and amount to afford graduate students an adequate experience in diagnosis, therapy and operative technic. Ordinarily a minimum of 150 admissions and 1,500 outpatient visits a year is considered necessary for graduate training in this specialty.

A systematic course of instruction should be offered with regular lectures and demonstrations in clinical and operative ophthalmology. Instruction in surgical technic should be sufficient to enable residents and fellows to undertake operative

work on their own responsibility, especially toward the end of the graduate program.

17. OPHTHALMOLOGY-OTOLARYNGOLOGY.—A joint service in ophthalmology and otolaryngology should fulfil the requirements listed under each department except that three years of training and experience should constitute the minimum time required.

18. ORTHOPEDIC SURGERY.—After Jan. 1, 1940, candidates for certification must have completed one year of internship, three years of concentrated instruction in orthopedic surgery and two years of subsequent practice in this special field. Knowledge of the basic sciences related to orthopedic surgery is also required.

As preliminary training the Council recommends one year of general surgery in addition to the internship. Surgical and orthopedic facilities must be satisfactory and clinical material sufficient to afford graduate students adequate experience in the correction of congenital and acquired deformities and in the treatment of fractures and other acute and chronic disorders which interfere with the proper function of the skeletal system and its associated structures.

Both hospital and outpatient facilities are desirable, and institutions offering graduate instruction should treat a minimum of 200 inpatients annually. Students should become thoroughly familiar with all methods of diagnosis and treatment, corrective exercises, physical therapy, operative procedures and the use of orthopedic appliances. Instruction in surgical technic should be sufficient to enable residents and fellows to undertake operative work on their own responsibility, especially toward the end of the graduate program.

Graduate study is recommended in the fundamental sciences of anatomy, embryology, physiology, pathology, bacteriology and biochemistry. Clinical instruction should include teaching rounds and departmental conferences.

19. OTOLARYNGOLOGY.—The qualifications for special practice in this field include an approved internship and three years of graduate preparation, with at least one and preferably two years in recognized residencies or basic courses followed by private practice in otolaryngology.

Residencies and fellowships in otolaryngology should aim to provide adequate clinical and operative experience and additional opportunities, if possible, for graduate study in the related basic sciences of anatomy, embryology, histology, physiology, pathology, bacteriology and pharmacology.

Essential equipment for diagnosis and surgery should be available, including an audiometer and other special apparatus depending on the scope of the service. The department should further provide histologic and pathologic material for demonstrations and study and preferably facilities for experimental surgery and dissection of the head and neck. The clinical material should be sufficient in variety and amount to provide adequate training in the various divisions of the service, which might advantageously include the field of bronchoscopy. It is generally assumed that a graduate service would require a minimum of 400 admissions a year and at least 3,500 visits in the outpatient department.

The training should include a systematic course of instruction with lectures and demonstrations on clinical and technical subjects pertaining to the various phases of otolaryngology. Instruction in surgical technic should be sufficient to enable residents and fellows to undertake operative work on their own responsibility, especially toward the end of the graduate program.

20. PATHOLOGY.—(See Department of Pathology, section IV.)

21. PEDIATRICS.—To qualify for certification in pediatrics a candidate must have completed five years of training and practice after graduation from an approved medical school. The requirements include an approved internship of one year, a service of two years in a pediatric center and two additional years of specialized study or practice. Although the training need not be continuous or in the same institution, it is desirable that the educational program be systematized in the form of residencies or fellowships of from one to three years' duration.

Clinical training should be obtained in general medical pediatrics, *nutritional disorders, care of newborn infants,* preventive pediatrics and outpatient clinics in the various departments of medical pediatrics. Correlative studies are recommended especially in contagion, well baby clinics, mental deficiencies, neurologic disorders of children and behavior problems. Sufficient time should also be devoted to the fundamental subjects of physiology, embryology, nutrition, growth and development.

In the wards and in the clinics the residents and fellows should be permitted to assume individual responsibility in diagnostic and therapeutic procedures and case management. They should actively participate in teaching rounds, clinical-pathologic conferences, departmental seminars and all other functions designed to improve the quality of the clinical and educational service. To supply an adequate amount and variety of teaching material a department should provide a minimum of approximately 200 annual admissions in general medical pediatrics.

22. PHYSICAL THERAPY.—The department should be under the direction of a physician qualified by training and experience in physical therapy. He should spend sufficient time in the department daily to supervise actually the work of the graduate students and technicians. Adequate space and apparatus should be furnished in the department for all phases of the work. The clinical material should be sufficient in kind and amount to enable the residents and fellows to observe and study all forms of treatment in physical therapy. Both inpatient and outpatient clinical material should be available.

The training should include (*a*) the study of certain fundamental subjects: physics of light, heat, electricity and mechanics; anatomy, with special reference to the peripheral nervous system, muscles, blood vessels, bones and joints; physical chemistry as related to physical therapy; physiology; (*b*) clinical and hospital training in the study and treatment of patients by various physical agents—light therapy, thermotherapy, fever therapy, hydrotherapy, electrotherapy and mechanotherapy. Emphasis should be placed on subjects related to physical therapy such as orthopedics, neurology, roentgenology, dermatology and general medicine.

A minimum of three years of special training is considered necessary for a physician to qualify as a specialist in physical therapy.

23. PLASTIC SURGERY.—(See Surgery.)

24. PSYCHIATRY AND NEUROLOGY.—Specialized training and experience of at least five years is essential for certification in neurology or in psychiatry. (To qualify in both fields a minimum of six years is required.) The requisite training consists of three full years of study after the general internship, and two or three additional years of practice or study in psychiatry or neurology or both. During the period of training a program of graduate studies should run concurrently with clinical instruction, covering the fundamentals of neuroanatomy, neuropathology, neurophysiology, psychobiology and psychopathology.

In institutions offering residencies and fellowships of from one to three years' duration, emphasis should be placed on the educational features of the service, and the residents should receive regular instruction from members of the staff in general orientation in the specialty, and diagnostic and therapeutic procedures and methods of clinical study as well as in the organization of ward services. Administrative details, progress notes, and contact with patients' relatives should be kept sufficiently within bounds so that the residents may employ their time in the study and treatment of neurologic and psychiatric disorders. Emphasis should be placed on the study of etiology, pathogenesis, symptomatology and course of the various diseases so that the residents may develop skill and accuracy in diagnosis, as well as mature judgment based on knowledge of the natural history of the diseases and resourcefulness in therapy.

A rotating assignment in psychiatry is essential to give residents adequate experience on the admission services, on the infirmaries and wards, in the therapeutic divisions and in the outpatient clinics. A resident in neurology should have adequate contacts with psychopathic departments, general medicine, pediatrics, contagious disease and tuberculosis services so that he may become familiar with neurologic complications of general diseases, and he should also witness or assist at whatever neurosurgical operations are performed in the hospital. Teaching rounds, clinical and pathologic conferences and seminars are essential for clinical instruction in both fields.

The clinical material must be adequate in kind and amount. Between 200 and 400 admissions a year per resident is considered desirable. Smaller numbers prevent proper survey of the field of neuropsychiatric disorders; larger numbers are incompatible with adequate study of the patients admitted. Similar requirements apply in institutions where separate residencies are offered in the field of epilepsy and mental deficiencies, except that not more than one year of residency in either type of hospital will be considered as preparation for the specialty of psychiatry or neurology. It must be emphasized that residencies in psychiatric and neurologic hospitals are educational in character and that, of the full time psychiatric or neurologic staff of such hospitals, only those physicians who serve primarily on an educational basis come within the residency classification of the Council.

25. RADIOLOGY.—(See Department of Radiology, section III.)

26. SURGERY.—The requirements for certification by the American Board of Surgery include an approved internship and at least five additional years of special training in surgery. During this period the entire time should be devoted to surgical training supplemented by sufficient experience in the basic sciences of anatomy, physiology, pathology, bacteriology and biochemistry.

Residencies and fellowships, organized in accordance with these requirements may be of from one to five years' duration but need not necessarily be confined to one institution. In aggregate, however, the training should coincide with the plan described. Individual residencies may be conducted in general surgery, fractures, neurosurgery, plastic surgery, thoracic surgery, traumatic surgery and other surgical divisions now organized as independent specialties. As preliminary training for residencies and fellowships in such specialties as neurosurgery, orthopedics, plastic surgery, thoracic surgery and urology the Council recommends one year of general surgery in addition to the internship.

All surgical departments can readily subscribe to the same general plan of training, although their scope of service may show considerable variation. Training in most of the surgical specialties is ordinarily limited to one division, but residencies in general surgery may well encompass the entire surgical field with the possible exception of ophthalmology and otolaryngology.

It is essential that adequate supervision be maintained by a competent department head responsible for the organization of the graduate program. He should personally direct the plan of clinical and operative training but may well rely on qualified assistants to supervise certain details of the educational service. Residencies and fellowships should emphasize careful training in diagnosis, preoperative therapy and postoperative care. This requires systematic bedside instruction, correlation of clinical and operative data, the study of gross and microscopic pathology, collateral reading, and accurate observations throughout the entire course of the disease. Supplementary instruction should be furnished in the form of departmental seminars, teaching rounds and clinical-pathologic conferences, usually on a weekly basis. It is also desirable that facilities be available for anatomic dissection and experimental surgery on animals or on the cadaver. Surgical training should be obtained under the careful guidance and supervision of competent specialists. It should be sufficient in amount to insure a reasonable degree of technical proficiency and thus enable the residents and fellows to undertake operative work on their own responsibility, especially toward the end of the graduate program.

Equipment and facilities for general and special surgery must be adequate to meet the needs of the service. The clinical material should likewise be sufficient to furnish adequate experience and training in diagnosis, therapy and operative technic. Accordingly it is suggested that general surgical services provide approximately 400 annual admissions per resident. The same amount may not be necessary for separate residencies in fractures, neurosurgery, plastic surgery, thoracic surgery and traumatic surgery, but even in the most limited of these specialties there should be at least 150 patients treated annually.

27. THORACIC SURGERY.—(See Surgery; also Tuberculosis.)

28. TRAUMATIC SURGERY.—(See Surgery.)

29. TUBERCULOSIS.—(See Medicine.)

30. UROLOGY.—For certification in urology a minimum of five years of special training and practice is required after the internship. This period of preparation should include an active clinical experience of at least eighteen months, graduate training in anatomy, physiology, pathology and other basic sciences, and not less than two years of additional practice.

As preliminary training for residencies and fellowships in urology, the Council recommends one year of general surgery in addition to the internship. Graduate instruction should be organized in accordance with the aforementioned requirements. It should be systematic and progressive in character to the end that adequate training may be obtained in diagnosis, therapy, cystoscopic examinations, pyelography and operative procedures, all under the supervision of a well qualified urologist.

Instruction in the fundamental branches can readily be integrated with the clinical experience. Particular emphasis should be placed on the study of pathology, and residents and fellows might well be required to examine both grossly and microscopically all urologic specimens removed during their term of service. Teaching rounds and departmental conferences are considered essential for systematic clinical instruction.

The department must provide adequate facilities for surgery and special urologic procedures.

Training in surgical technic should be sufficient to enable residents and fellows to undertake operative work on their own responsibility, especially toward the end of the graduate program.

The clinical material should be sufficient in amount and variety to fulfil the teaching needs of the service. It is generally assumed that a minimum of 200 inpatients a year is necessary for advanced training in urology. This amount should be supplemented by outpatient material in cystoscopic and general urologic clinics. Access to gonorrheal clinics would also be of advantage.

X. RESIDENT-INTERN RELATIONSHIP

Those hospitals training both residents and interns should recognize their responsibility to both groups and not curtail too sharply the opportunities ordinarily given to interns by an excess of solicitude for the residents. The residents may, with profit, teach the interns, supervise their records and direct the treatments which interns administer. They should not, however, act so as to diminish the contact of the interns with the attending men or assume the supervisory or disciplinary functions of the staff intern committee.

XI. RECORDING OF CREDIT

A successful completion of a residency or fellowship is recorded in the biographic files of the American Medical Association. It is important, therefore, that all institutions approved for fellowships and residencies in specialties make annual reports to this office. Periods of service in institutions approved by the Council for fellowships and residencies in specialties are given full credit without further inquiry. Services in unapproved institutions are recorded as unclassified assignments.

Arrangements are now being made for an interchange of information between the Council and the examining boards responsible for the certification of specialists. In this way the study and appraisal of residencies and fellowships will lead to the formulation of lists approved by the Council and acceptable to the respective boards.

The specialty boards listed below have been approved by the Council in accordance with the following resolutions of the House of Delegates:

Resolved, That the Council on Medical Education and Hospitals is hereby authorized to express its approval of such special examining boards as conform to the standards of administration formulated by the Council; and be it further

Resolved, That the Board of Trustees of the American Medical Association be urged to use the machinery of the American Medical Association, including the publication of its Directory, in furthering the work of such examining boards as may be accredited by the Council.

American Board of Anesthesiology,
Paul M. Wood, Secretary-Treasurer,
745 Fifth Avenue, New York.

American Board of Dermatology and Syphilology,
C. Guy Lane, Secretary-Treasurer,
416 Marlboro Street, Boston.

American Board of Internal Medicine,
William S. Middleton, Secretary-Treasurer,
1301 University Avenue, Madison, Wis.

American Board of Obstetrics and Gynecology,
Paul Titus, Secretary-Treasurer,
121 South Highland Avenue, Pittsburgh.

American Board of Ophthalmology,
John Green, Secretary,
6830 Waterman Avenue, St. Louis.

American Board of Orthopaedic Surgery,
Fremont A. Chandler, Secretary,
6 North Michigan Avenue, Chicago.

American Board of Otolaryngology,
William P. Wherry, Secretary,
107 South Seventeenth Street, Omaha.

American Board of Pathology,
Frank W. Hartman, Secretary-Treasurer,
2799 West Grand Boulevard, Detroit.

American Board of Pediatrics,
C. Anderson Aldrich, Secretary,
722 Elm Street, Winnetka, Ill.

American Board of Psychiatry and Neurology,
Walter Freeman, Secretary,
1028 Connecticut Avenue N.W., Washington, D. C.

American Board of Radiology,
Byrl R. Kirklin, Secretary,
102 Second Avenue S.W., Rochester, Minn.

American Board of Surgery,
J. Stewart Rodman, Secretary,
225 South Fifteenth Street, Philadelphia.

American Board of Urology,
Gilbert J. Thomas, Secretary,
1009 Nicollet Avenue, Minneapolis.

XII. Admission to the Approved List

Institutions that wish to be approved for residencies or fellowships should apply to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago. Application blanks will be furnished and arrangements made for a personal visit of inspection by a member of the Council's staff. Approval is based on full compliance with the foregoing standards. Recognition may be withdrawn whenever it appears that the institution no longer conforms to these essentials or when the positions remain vacant for a period of two or more years.

Essentials for Approved Examining Boards in Specialties

I. Organization

1. A special examining board to be approved by the Council should represent a well recognized and distinct specialty of medicine.

2. It should be composed of representatives of the national organizations of that specialty including the related section of the American Medical Association.

3. It should be incorporated.

4. A special board should:

   a. Determine whether candidates have received adequate preparation as defined by the board.

   b. Provide a comprehensive test of the ability and fitness of such candidates.

   c. Certify to the competence of those physicians who have satisfied the requirements of the board.

II. Definition of Special Fields

The following branches of medicine at present are recognized as suitable fields for the certification of specialists:

1. Internal Medicine
2. Surgery
3. Pediatrics
4. Obstetrics and Gynecology
5. Ophthalmology
6. Otolaryngology
7. Dermatology and Syphilology
8. Neurology and Psychiatry
9. Urology
10. Orthopedic Surgery
11. Radiology
12. Pathology
13. Anesthesiology

III. Qualification of Candidates

Each applicant for admission to the examination should be required to present evidence that he has met the following standards:

A. General Qualifications.

1. Satisfactory moral and ethical standing in the profession.
2. A license to practice medicine.
3. Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies should not be required.

B. Professional Education.*

1. Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.
2. Completion of an internship of not less than one year in a hospital approved by the same Council.

C. Special Training.**

(To be effective not later than Jan. 1, 1942.)

1. A period of study after the internship of not less than three years in clinics, dispensaries, hospitals or laboratories recognized by the same Council as competent to provide a satisfactory training in the special field of study.
2. This period of specialized preparation shall include,
   a. intensive graduate training in anatomy, physiology, pathology, and the other basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in the specialty in question;
   b. an active experience of not less than eighteen months in hospitals, clinics, dispensaries or diagnostic laboratories recognized by the Council as competent in the specialty;
   c. examinations in the basic medical sciences of a specialty as well as in the clinical, laboratory and public health aspects.
3. An additional period of not less than two years of study and/or practice.

IV. Withdrawal

For reasons which are deemed sufficient, in the judgment of the Council on Medical Education and Hospitals, the recognition extended by the American Medical Association to holders of certificates from special examining boards may be withdrawn.

* Candidates who submit credentials from institutions outside of the United States and Canada should be required to pass the examination of the National Board of Medical Examiners.

** Candidates whose special training has been received outside of the United States and Canada should submit credentials satisfactory to the examining boards.

REPORT OF THE COUNCIL ON SCIENTIFIC ASSEMBLY

To the Members of the House of Delegates of the American Medical Association:

The death of Dr. J. C. Flippin of Charlottesville, Va., a member of the Council on Scientific Assembly and of the House of Delegates, occurred on Feb. 16, 1939. Dr. Flippin had served as a member of the Council since 1936 and had represented the Medical Society of Virginia in the House of Delegates of the American Medical Association since 1934. As dean of the University of Virginia Department of Medicine and through constant attendance at meetings of important professional societies and active participation in the affairs of this Association and of other medical organizations, Dr. Flippin enjoyed a wide acquaintance with the physicians of the United States and was held in high esteem by all who were privileged to know him and especially by those whose privilege it was to be associated with him in some official capacity. He won the respect and affection of the members of this Council because of

his courteous bearing, his earnestness of purpose, his tolerance of the opinions of others, his readiness to carry his full share of responsibility, his devotion to duty and his loyalty to the highest professional ideals and to the organizations in whose service he was engaged.

The usual meetings of the Council on Scientific Assembly were held during the annual session at San Francisco, and the regular interim meeting of the Council was held in Chicago on Dec. 2, 1938, at which time the annual conference of the Council with the section officers was also held.

PROGRAM CHANGES

As reported to the House of Delegates at the San Francisco session, consideration has been given by the Council to the possibility of effecting changes in the nature of the programs of the scientific sections and the General Scientific Meetings. The Council has had the highly valued suggestions and advice of the section secretaries with respect to this matter, and it will be noted that certain innovations in the scientific programs are being instituted at this session.

A new feature of the program of the General Scientific Meetings will be panel discussions on Tuesday afternoon. The program at that time will be divided into medical and surgical sessions. The program of the medical session will be devoted to a discussion, to be directed by a moderator, which will deal with etiology, therapeutic methods and indications and public health aspects of pneumonia. The program of the surgical session will be given over to a discussion of diseases of the biliary tract, dealing with physiology, differential diagnosis and other important phases of this general subject and will be presented in the same manner as that of the medical session.

For many years it has been an unwritten rule observed by those in charge of the preparation of scientific programs that physicians residing in the city in which an annual session of the American Medical Association is held should not participate as contributors of papers. The Council on Scientific Assembly and the section officers have felt that the operation of this rule has at times prevented the presentation of papers of significant importance by physicians especially well qualified to discuss topics of general interest. An important innovation in this year's program involves the presentation of a group of papers in the program of the General Scientific Meetings by local physicians.

In some of the section meetings at this annual session the method of presentation of the programs will be changed to some extent. At least one section will devote one of its sessions to a panel discussion, and in certain instances two sections have combined their sessions on Friday into symposiums. It is proposed that experiments somewhat similar to those that are being undertaken this year be continued with the view of developing scientific programs of more general interest and in such manner as to afford opportunity for greater dissemination of helpful information and perhaps for greater participation in discussions by members of the sections and by those who attend the General Scientific Meetings.

The official program of the St. Louis session is submitted as a part of the report of the Council on Scientific Assembly. The programs of the sections are prepared by the officers of the sections, while the program of the General Scientific Meetings has been prepared under the direction of the chairman of the Council on Scientific Assembly.

At a proper time the Council will submit to the House of Delegates nominations for Affiliate Fellowship.

The members of the Council desire to make grateful acknowledgment of the helpful assistance received at the hands of the officers and especially of the secretaries of all the scientific sections.

Respectfully submitted.

JAMES E. PAULLIN, Chairman.
J. GURNEY TAYLOR.
A. A. WALKER.
CLYDE L. CUMMER.
ROCK SLEYSTER, President-Elect. } Ex officio.
MORRIS FISHBEIN, Editor, THE JOURNAL. } Ex officio.
OLIN WEST, Secretary. } Ex officio.

OFFICIAL NOTES

RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title Your Health, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).

Changes in this time will be necessary to take into consideration daylight saving time. Announcement of this change will appear in advance in THE JOURNAL. Owing to network conflicts the Chicago broadcast does not occur at 1 p. m. Wednesday but there is a rebroadcast from a recording over Station WENR at 8 o'clock each Monday evening. The program broadcast each Monday is identical with the network program of the preceding Wednesday.

It has been necessary to curtail the length of the series by omitting the last two programs, which would have been broadcast June 14 and June 21. The series, therefore, will end with the broadcast scheduled for June 7.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

April 12. Learning to Live.
April 19. "Accidents Don't Just Happen—"
April 26. What Is a Doctor?

WOMAN'S AUXILIARY

Michigan

The Kalamazoo auxiliary distributed food to needy families in the community at Christmas.

Mrs. P. L. Thompson gave a talk on her recent world tour at the November meeting of the auxiliary to the Kent County Medical Society, which was attended by 158 members. The auxiliary has placed 172 six month subscriptions to *Hygeia* in the county rural schools and is collecting all printed articles pertaining to medical legislation. Dr. Ruth Herrick, chairman of the section on dermatology and syphilology of the Michigan State Medical Society, spoke on "The New Social Hygiene Program" at a recent meeting of the auxiliary, discussing "Shadow on the Land" by Surgeon General Parran.

Dr. Claire E. Straith spoke on the projects of the auxiliary to the Washtenaw County Medical Society at the Michigan Union, Ann Arbor, November 8. Members of the county medical society joined the auxiliary, hearing Dr. Straith speak on plastic surgery.

The auxiliary to the Saginaw County Medical Society has given subscriptions to *Hygeia* to twenty rural schools.

Oklahoma

The Pontotoc County auxiliary was addressed January 18 by Mrs. E. M. Gullatt on socialized medicine.

The women's auxiliary to the Woodward County Medical Society meets on alternate months with the doctors and shares the program. Dr. Coyne Campbell, Oklahoma City, spoke on psychoanalysis and Dr. Johnson of the staff of the Oklahoma State Hospital for Insane reviewed results of insulin treatment of dementia praecox patients, December 14.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Short Course in Internal Medicine.—The division of medical extension, Tulane University of Louisiana, New Orleans, in cooperation with the Medical Association of the State of Alabama, opened a course in internal medicine in Tuscaloosa April 3. Sessions will be held April 10, 24, May 1, 8 and 15. The instructors are Drs. Virgil P. Sydenstricker, professor of medicine, University of Georgia School of Medicine, Augusta, and Julius L. Wilson, associate professor of medicine at Tulane. Dr. Sydenstricker will discuss "Nutritional Diseases," "Diabetes," and "Nephritis," and Dr. Wilson, "Cardiac Diseases," "Acute Infections" and "Pulmonary Tuberculosis."

State Medical Meeting in Montgomery.—The Medical Association of the State of Alabama will hold its annual session at the Whitley Hotel, Montgomery, April 18-20, under the presidency of Dr. Seale Harris, Birmingham, and with the Montgomery County Medical Society acting as host. Out-of-state speakers will include:

Dr. John S. Turberville, Century, Fla., Prostatic Diseases from the Standpoint of the General Surgeon.
Dr. Giles S. Bryan, Amory, Miss., Reducing the Pneumonia Death Rate.
Dr. Edward N. DeWitt, Bridgeport, Conn., Intra-Ocular Tumors.
Dr. Tinsley R. Harrison, Nashville, Tenn., The Therapeutic Approach to High Blood Pressure.
Dr. Virgil P. W. Sydenstricker, Augusta, Ga., The Changing Concepts of Deficiency Diseases.
Dr. Clyde Brooks, New Orleans, Blood Sedimentation.
Dr. Adrian Taylor, Clifton Springs, N. Y., Clinical Aspects of Thyroid Disease.
Dr. William H. Anderson, Booneville, Miss., The Community Hospital.
Dr. Maxwell E. Lapham, New Orleans, Postgraduate Study.

Dr. George T. Pack, New York, will deliver the Jerome Cochran Lecture Wednesday morning on "Recent Advances in the Radiation Therapy of Cancer." There will be a symposium on hospitalization and medical care of the indigent Tuesday morning. Wednesday afternoon a feature will be the unveiling of a statue to James Marion Sims at which the speakers will be Dr. Marye Y. Dabney, Birmingham, on "James Marion Sims, 'The Father of Modern Gynecology'"; Mrs. Marie Bankhead, director, department of archives and history of the state of Alabama, Montgomery, "James Marion Sims, 'Benefactor of Womankind'," and Gov. Frank M. Dixon, who will accept the monument. A public session will be held Wednesday evening on "Medical Education in Alabama." The fourteenth annual meeting of the woman's auxiliary will be at the Whitley April 18-19.

ARKANSAS

Society News.—The Sebastian County Medical Society was addressed February 14 by Dr. Raymond T. Smith, Fort Smith, on "The Appearance of the Ear Drum in Certain Middle Ear Conditions."——At a meeting of the Lawrence County Medical Society February 14 Drs. John B. Elders, Walnut Ridge, discussed syphilis and Charles C. Townsend, Walnut Ridge, "Medicine as It Is or State Medicine?"——The Benton County Medical Society was addressed in Rogers February 9 by Drs. Miles E. Foster on "Sedimentation Rate in Gynecology"; Sidney J. Wolfermann, "Socialized Medicine," and William R. Brooksher, "Roentgen Ray Treatment of Infections." All are of Fort Smith. The society was addressed in Bentonville March 9 by Drs. Jesse D. Riley, State Sanatorium, on "Collapse Therapy" and Clyde L. McNeil, Rogers, "Sulfanilamide."

CALIFORNIA

Bequest to Library.—The income from a fund of $10,000 will be paid to the library of the Los Angeles County Medical Association, Los Angeles, in accordance with a stipulation in the will of the late Dr. Walter Jarvis Barlow. The name of Dr. Barlow has been prominently associated with the history of the library. In 1906 he erected a building to house what was then known as the Hendryx Medical Reference Library. In 1907 a building was opened in the name of the Barlow Medical Library Association. In 1932 negotiations were started to transfer the library to the county medical association, which in 1934 opened its permanent home, providing quarters for the library. The entire collection is known as the Library of the Los Angeles County Medical Association.

CONNECTICUT

Society News.—Dr. Emil Novak, Baltimore, recently addressed a public meeting sponsored by the Medical Information Bureau of the Hartford Medical Society and the Hartford County Medical Association on "Cancer: A Message of Hope."

Changes in Health Officers.—The *Connecticut Health Bulletin* announces the following changes in health officers:

Dr. Cyrus E. Pendleton, appointed in Colchester to succeed the late Dr. Edward J. Howland.
Dr. Harold A. Howard of Wethersfield to succeed the late Dr. Edward G. Fox.
Dr. Robert C. Sellew of Canaan.
Dr. Charles K. Skreczko Jr. of Shelton to succeed Dr. William S. Randall.
Dr. Joseph S. Stygar of Derby to succeed Dr. Thomas F. Plunkett.
Dr. John M. Renehan of Ansonia to succeed Dr. Louis Howard Wilmot.
Dr. George E. Roch of Willimantic to succeed Dr. Reuben Rothblatt.

DISTRICT OF COLUMBIA

University News.—Reuben L. Kahn, D.Sc., Ann Arbor, Mich., delivered a series of lectures on "Interpreting the Serology of Syphilis" at the U. S. Naval Medical School, Naval Medical Center, Washington, March 21-24.

Public Health Forum.—Georgetown University recently conducted its second annual public health forum. Dr. Ella Oppenheimer opened the series of lectures February 2 with a discussion of "Child Welfare." Other speakers were Dr. Custis Lee Hall, February 9, on "Crippling Conditions in Children"; J. Edward Routh, Ph.D., February 16, "Problem Children," and Fred R. Sanderson, February 23, "Common Household Poisons." The series ran six weeks.

GEORGIA

State Medical Meeting at Atlanta.—The ninetieth annual session of the Medical Association of Georgia will be held at the Biltmore Hotel, Atlanta, April 25-28, under the presidency of Dr. Grady N. Coker, Canton, and with the Fulton County Medical Society acting as host. The presidential address will be entitled "Modern Trends of Medical Practice." The speakers will include:

Dr. Hartwell Joiner, Gainesville, Prophylactics and the Common Cold
Dr. Carl C. Garver, Atlanta, Pneumolysis as an Adjunct of the Treatment of Pulmonary Tuberculosis.
Dr. Ernest F. Wahl, Thomasville, Effect of Nervous Influences on Nutrition.
Dr. Joseph Yampolsky, Atlanta, Use of Sulfanilamide in Routine Pediatric Practice.
Dr. Harrison H. Shoulders, Nashville, Tenn., Some Phases of Medical Economics.
Hon. Robert F. Maddox, Atlanta, chairman, state board of health, The Social and Economic Value of Health.
Dr. Crawford F. Barnett Jr., Atlanta, Chronic Gastritis.

Dr. John S. Lundy, Rochester, Minn., will deliver the Abner Wellborn Calhoun Lecture Wednesday on "Suggestions for the Use of Anesthetics and Analgesics in General Medical Practice." A symposium on industrial surgery will be held the same day and one on cancer Thursday. Entertainment will include the annual luncheon of the Georgia Radiological Society, and the annual dinners of the alumni of the medical schools of Emory and Georgia universities. Speakers before the woman's auxiliary, which will meet April 25-27, will include Drs. William H. Myers, Savannah, president-elect of the state medical association, on "Evolution in the Practice of Medicine."

ILLINOIS

Society News.—Dr. Lawrence F. Weber, Chicago, discussed common diseases of the skin before the Lawrence County Medical Society in Lawrenceville April 5.——The Will-Grundy County Medical Society was addressed in Joliet by Dr. Stanley Gibson, Chicago, April 7 on acute conditions of the abdomen in children.——At a meeting of the Madison County Medical Society, Alton, April 7, Dr. John S. Coulter, Chicago, discussed the "Home Treatment of Chronic Arthritis."

Chicago

Institute for Negro Health Workers.—The Tuberculosis Institute of Chicago and Cook County will conduct a two day institute for Negro health workers in cooperation with the National Tuberculosis Association April 17-18 at the Y. M. C. A., Wabash Avenue and Thirty-Eighth Street. The program will cover the following four themes: A modern con-

cept of tuberculosis, what it is, how it develops; best methods for controlling tuberculosis, including case-finding and hospitalization; the organized campaign against tuberculosis with special stress on Negro organization, and the possibility of controlling tuberculosis.

Society News.—Dr. Arthur Steindler, Iowa City, among others, addressed the Chicago Orthopedic Society and the Chicago Roentgen Society March 9 on "Compensation and Derotation in the Treatment of Scoliosis."——Dr. Frances Hannett discussed "What Constitutes a Psychiatric Problem in General Practice" before the Chicago Council of Medical Women March 22 and Dr. Adelaide M. Johnson, "Treatment of Children's Problems with Special Reference to Play Therapy."——The Chicago Society of Internal Medicine was addressed March 27, among others, by Drs. Heinrich Necheles, Rudolf Schindler and Rubin L. Gold on "Surgical Gastritis: A Study on the Genesis of Gastritis Associated with Ulcers."——Dr. Leo K. Campbell gave a public lecture at the Chicago Woman's Club March 8 under the auspices of the Chicago Medical Society on "Eat, Drink and Grow Fat."——The Chicago Pediatric Society was addressed March 21 by Drs. Adrian D. M. Kraus on "Periodic Paralysis"; Eugene T. McEnery, "Epidermoid Cysts of the Spleen," and Lloyd E. Harris, "Bromide Intoxication in a Child Four Years of Age."——At a meeting of the Chicago Ophthalmological Society March 20 the speakers were Dr. John G. Bellows and Herman Chinn, Ph.D., on "Distribution of Sulfanilamide in the Eye"; Drs. Bertha A. Klien, "Concerning the Dictyoma Retinae" and Samuel S. Blankstein, Milwaukee, "Comparison of Visual Acuities."

INDIANA

Tri-State Meeting.—The annual meeting of the Northern Tri-State Medical Association, including Michigan, Ohio and Indiana, will be held at the Hotel Oliver, South Bend, April 11. The speakers will include:

Dr. Albert C. Furstenberg, Ann Arbor, Mich., Nasal Accessory Sinus Disease in the General Practice of Medicine.
Dr. Daniel P. Foster, Detroit, Newer Concepts of Diabetes Mellitus.
Dr. Charles G. Johnston, Detroit, Physiologic Implications in the Management of Intestinal Obstruction.
Dr. David Edwin Robertson, Toronto, Fractures in Children.
Dr. Robert M. Moore, Indianapolis, Diagnosis and Treatment of Heart Disease.
Dr. A. Jerome Sparks, Fort Wayne, Ind., Calculi in the Upper Urinary Tract.
Dr. Frank C. Walker, Indianapolis, Relation of Cervical Lesions to Carcinoma of the Cervix Uteri.
Dr. Harold N. Cole, Cleveland, Relapse in Syphilis: Its Importance in Diagnosis, the Public Health Aspect, and Its Treatment.
Dr. Waldo E. Nelson, Cincinnati, Treatment of Diabetes Mellitus in Children.
Dr. Bruce K. Wiseman, Columbus, Ohio, The Cytolytic Functions of the Spleen in Relation to the Blood Diseases.

IOWA

Society News.—Dr. Soma Weiss, Boston, will discuss "Cardiac Asthma and Associated Syndromes" before the Linn County Medical Society, Cedar Rapids, April 24.——Dr. Morris Edward Davis, Chicago, addressed the Black Hawk County Medical Society, Waterloo, March 14 on "Endocrine Therapy in Obstetrics and Gynecology."

Grant to Study Infant Nutrition.—Dr. Philip C. Jeans, professor of pediatrics, State University of Iowa College of Medicine, Iowa City, has received a grant of $7,500 from the Borden Company for the continuation of his investigations in infant nutrition. The grant was made available through the Council for Pediatric Research of the American Academy of Pediatrics.

KANSAS

Society News.—Dr. James Roscoe Miller, Chicago, addressed the Shawnee County Medical Society February 6 on "Diagnosis and Treatment of Coronary Occlusion."——The Wyandotte County Medical Society was addressed in Kansas City February 21 by Drs. Eugene D. Liddy Jr. and Frederic A. Speer on asthma and diagnosis of fever in infancy, respectively.

LOUISIANA

Instruction for Medical Reserve Officers.—The department of graduate medical studies of Tulane University of Louisiana School of Medicine, New Orleans, will conduct a two weeks course of instruction for medical reserve officers of the fourth corps of the U. S. Army April 11-22.

Society News.—Dr. Charles E. Galloway, Evanston, Ill., discussed "Pathology of the Cervix" before the Orleans Parish Medical Society and the New Orleans Gynecological and Obstetrical Society March 13. The parish medical society was addressed February 27 by Drs. Carlo J. Tripoli on "Acute Lymphocytic [illegible] and Rudolph Matas, "Recent Observations [illegible] in the Spanish War."——Dr. Clarence P. May discussed "Medical Psychology" before the Rapides Parish Medical Society, Alexandria, February 6.

MARYLAND

Society News.—A symposium on marihuana was presented before the Baltimore City Medical Society February 3 by Rowland K. Adams, judge, supreme bench of Baltimore City; Dr. Manfred S. Guttmacher, chief medical officer of the supreme bench, and Mr. H. J. Wolin [illegible] of the treasury department, bureau of [illegible] D. C. At a meeting of the society March 3, the speakers included Drs. Henry J. Walton on "What Can Be Done for Patients Suffering from Far Advanced Bone Metastasis," and Richard T. Shackelford, "Peritoneoscopy, Its Uses and Limitations."——Dr. Thomas Archibald Malloch, librarian of the New York Academy of Medicine, gave an illustrated lecture on William Osler before the Osler Historical Club, Baltimore, March 21.

MASSACHUSETTS

The Cutter Lecture.—Dr. Frederick F. Russell, professor of preventive medicine and epidemiology, emeritus, Harvard Medical School, Boston, will deliver the annual Cutter Lecture in Preventive Medicine at the school April 17. His subject will be "The History of Yellow Fever as an Illustration of Methods of Study and Control of Virus Diseases."

Health Education Institute.—The New England Health Education Association, in cooperation with the departments of education, state departments of health and tuberculosis associations of the New England states, will hold an institute on health education April 21-22 at the William Barton Rogers Building, Massachusetts Institute of Technology, Cambridge.

MICHIGAN

Society News.—Dr. Jacob P. Greenhill, Chicago, discussed "The Use of Androgens in Gynecology" before the Detroit Obstetrical and Gynecological Society March 7.——Dr. William P. Tew, London, Ont., discussed "Diagnosis and Treatment of Hemorrhage Late in Pregnancy" before the Genesee County Medical Society in Flint February 8.——Dr. Morris Edward Davis, Chicago, addressed the Berrien County Medical Society in Benton Harbor March 16 on "Present Day Diagnosis and Treatment of Hemorrhage Late in Pregnancy."

Venereal Disease Director Appointed.—Dr. Thomas E. Gibson, Paw Paw, formerly director of the Van Buren County Health Department, has been appointed director of the venereal disease division of the Michigan State Department of Health. Previously Dr. Gibson was director of the Genesee County Health Department and of the Isabella County Health Department and in 1931 he served with the state department of health for six months on a Rockefeller Foundation scholarship. He graduated at the College of Medical Evangelists, Loma Linda-Los Angeles, in 1931.

Graduate Programs.—The attending staff of Receiving Hospital, Detroit, has arranged the programs of the monthly staff meetings for the remainder of this academic year as a continuing graduate activity, according to the Detroit *Medical News*. All former interns of the hospital are invited. The speakers at the meeting March 8 were Warren O. Nelson, Ph.D., professor of anatomy, Wayne University School of Medicine, Detroit, on "Physiology of the Ovarian Hormones"; Oliver Kamm, scientific director of research, Parke, Davis & Co., "The Standardization and Chemical Relationships of the Ovarian Hormones," and Dr. Ward F. Seeley, professor of gynecology and obstetrics at Wayne, "Hormonal Treatment of Menstrual Disorders."

Personal.—Dr. George McL. Waldie has resigned as medical superintendent of the Copper Country Sanatorium, Houghton, effective on the appointment of a successor. He has held the position for twelve years.——Dr. Robert B. Harkness, Hastings, director of the Barry County health department, was elected president of the State Council of Health at its advisory session with the state health commissioner in Lansing recently, succeeding Ura G. Rickert, D.D.S., Ann Arbor, who died Oct. 22, 1938. P. C. Lowery, D.D.S., Detroit, vice president of the American Dental Association, has been appointed a member of the council to serve the unexpired term of Dr. Rickert, which ends June 30, 1941.——Dr. Thomas Y. Ho, St. Johns, was recently reelected secretary of the Clinton County Medical Society for the sixteenth consecutive time.

MINNESOTA

Special Lecture.—Dr. Ludvig Hektoen, executive director, National Advisory Cancer Council, U. S. Public Health Service, Washington, D. C., will present the annual Minnesota Cancer Institute Lecture in Minneapolis April 17. His subject will be "Advances in the Knowledge and Control of Cancer."

State Radiologic Meeting.—The Minnesota Radiological Society held its spring meeting in St. Paul, March 18. The speakers included.

Ancel Keys, Ph D., and Dr. Hymer L. Friedell, Minneapolis, Roentgen Kymographic Studies in Cardiac Physiology.
Drs. Harry M. Weber and Clarence Allen Good Jr., Rochester, A Series of Interesting Duodenal Lesions
Drs. Clarence P. Truog and Raymond E. Burge, Minneapolis, Bone Atrophy. Report of an Unusual Case.
Dr. Henning M. Berg, Bismarck, N. D., The Practice of Radiology in Sweden

A symposium on radiation therapy of neoplasm of the stomach was presented by Drs. Arthur U. Desjardins, Rochester; Chauncey N. Borman, Cyrus O. Hansen and Russell W. Morse, Minneapolis; Edward Schons, St. Paul, and Wilhelm Stenstrom, Ph.D., Minneapolis. At the dinner, Drs. John L. McKelvey spoke on "Medical Experiences in China," and Harry M. Weber, Rochester, "Observations on Roentgenology in Europe."

MISSISSIPPI

Society News.—At a meeting of the Pike County Medical Society in McComb January 5 Drs. Emile F. Naef and Conrad G. Collins, New Orleans, spoke on "First Infection Type Tuberculosis in Childhood" and "Causes and Treatment of Vaginitis" respectively.——A joint meeting of the faculty of the University of Mississippi and the Northern Mississippi Medical Society was addressed in Oxford January 19 by Drs. Paul H. Harmon, Springfield, Ill., on "Suppurative Arthritis of the Hip"; Samuel W. Banks, Chicago, "The Intervertebral Destruction in Relation to Back Pain" and Edward L. Compere, Chicago, "Methods of Treatment for Fractures of the Neck of the Femur."

MISSOURI

Lectures on Pediatrics and Obstetrics.—The state board of health, the committee on maternal welfare of the Missouri State Medical Association and the extension service of the University of Missouri College of Agriculture are sponsoring lectures on obstetrics and pediatrics throughout the state.

Society Condemns Smoke Nuisance.—The St. Louis Medical Society recently adopted a resolution condemning the smoke nuisance in St. Louis as a danger to health and requesting city authorities to take immediate steps to "abolish the menace," newspapers reported. The resolution adopted by the society incorporates recent resolutions of the Ear, Nose and Throat Club, the Trudeau Society and the St. Louis Pediatric Society expressing opinions on the subject.

Retires as Superintendent of Barnes Hospital.—Dr. Louis H. Burlingham has retired after twenty-two years' service as superintendent of Barnes Hospital, St. Louis, effective April 1. According to *Modern Hospital,* Dr. Burlingham submitted his resignation a year ago, but the board of trustees of the hospital declined to accept it, granting him instead a leave of absence in the hope that he would regain his health. Dr. Burlingham graduated at Johns Hopkins University School of Medicine, Baltimore, in 1906

Society News.—Round table discussions form a new type of program recently introduced at meetings of the St. Louis Medical Society. The subject "Anemias—Clinical and Laboratory Diagnosis" was discussed February 24 with Dr. Goronwy O. Broun as the leader; "Anemia—Modern Methods of Treatment" was the theme March 3 with Dr. Lawrence D. Thompson as the leader.——Dr. Timothy Leary, Boston, discussed "The Most Important Professional Disease: Coronary Sclerosis" before the Kansas City Academy of Medicine February 17.

MONTANA

Personal.—Dr. Joseph L. Richards, Polson, has been reappointed county physician and secretary of the board of health of Lake County.

Society News.—Dr. Roy V. Morledge, Billings, was elected president of the Montana Academy of Ophthalmology and Oto-Laryngology at its semiannual meeting February 6 and Dr. Ashley W. Morse, Butte, was reelected secretary.

NEW YORK

State Medical Meeting at Syracuse.—The annual meeting of the Medical Society of the State of New York will be held April 24-27 at the Hotel Onondaga and the Hotel Syracuse, Syracuse, under the presidency of Dr. William A. Groat Syracuse. Two general sessions will be devoted to discussions of "Emergencies—Their Recognition and Treatment" and "Chronic Diseases—Their Early Recognition" In the first session the speakers will be:

Dr. Thew Wright, Buffalo, The Acute Abdomen
Dr. Edward A. Schumann, Philadelphia, Obstetrical Emergencies
Dr. Orman C. Perkins, Brooklyn, Acute Cerebral Emergencies
Dr. Edward C. Reifenstein, Syracuse, Cardiac Emergencies

In the second general session addresses will be made by:

Dr. Samuel A. Levine, Boston, Early Evidence of Cardiovascular Disease.
Dr. Francis Carter Wood, New York, Early Diagnosis of Cancer (the first A. Walter Suiter Lecture).
Dr. James Alexander Miller, New York, Early Diagnosis and Treatment of Pulmonary Tuberculosis
Dr. Clarence O. Cheney, White Plains, Early Recognition of Mental Diseases and Their Treatment.

Guest speakers who will address the sections will include

Dr. Thomas E. Jones, Cleveland, Surgical Treatment of Diverticulitis
Dr. Harry E. Bacon, Philadelphia, Extrarectal Metastatic Malignancy Simulating Primary Carcinoma of the Rectum
Dr. Trygve Gundersen, Boston, Diagnosis and Treatment of Diseases of the Cornea.
Dr. Maurice B. Strauss, Boston, Etiology and Treatment of True Toxemia of Pregnancy.
Dr. Harold R. Griffith, Montreal, Canada, Management of Complications Arising During Cyclopropane Anesthesia.
Drs. Bernard L. Wyatt, Robert A. Hicks and Harry E. Thompson, Tucson, Ariz., Chronic Arthritis—Differential Diagnosis—Special Treatment Methods: Medical, Orthopedic, Physical Therapy.
Dr. Donald Guthrie, Sayre, Pa., The Advantages of Silk in General Surgery.

The annual banquet will be at the Hotel Syracuse Tuesday evening April 25. Addresses will be made by Mr. Alexander Woollcott, New York; Drs. Logan Clendening, Kansas City, Mo.; William A. Groat, Syracuse, president of the society, and Terry M. Townsend, New York, president-elect.

New York City

The Salmon Lectures.—The seventh series of Thomas William Salmon Memorial Lectures will be delivered by Dr. Edward A. Strecker, chairman of the department of psychiatry, University of Pennsylvania School of Medicine, Philadelphia, at the New York Academy of Medicine April 14, 21 and 28. Dr. Strecker's general subject will be "Beyond Clinical Frontiers," and the individual titles, "The Massive Retreat from Reality"; "Crowd-Mindedness" and "Threats to Our Culture."

Long Island College Alumni Meeting.—The Alumni Association of the Long Island College of Medicine will hold its annual Alumni Day April 25. The morning program will include addresses by Drs. Frederick Schroeder on "Ancient and Modern Methods of Poisoning"; William A. Jewett, "Treatment of Pelvic Malignancies at the Long Island College Hospital" and Samuel Potter Bartley, "Reconstruction of the Arm and Hand" At a luncheon at the hospital Mr. Tracy Voorhees, president of the college board of regents, will speak on "A Layman's Thoughts on the Modern Problems Facing the Medical Profession," and Dr. Nathaniel P. Rathbun, "Some of the Problems Which the Medical Profession Is Facing Today." The annual banquet will be held in the evening at the Columbus Club with Drs. Frank L. Babbott, president of the college, John Sturdivant Read and Cassius H. Watson as the speakers

Health Calendar for the World's Fair.—Observances of special days have been scheduled by several organizations for the period of the New York World's Fair. A recent announcement includes:

May 1-8, National Child Health Week.
May 9, Dental Society of New York State.
May 12, National Hospital Day and Nurses' Day.
May 16, American Medical Association.
May 17, Red Cross Day
May 19, Tenth International Congress of Military Medicine and Pharmacy
May 31, Medical Society of the State of New York.
June 3, American Academy of Pediatrics
June 4, American Society for the Hard of Hearing.
June 18, New York City Health Department.
June 23, School Health Day.
June 27, County Medical Society Day.
October 21, National Health Day

Society News.—At a meeting of the Medical Society of the County of New York February 27 a symposium on the proposed national health program was presented by Drs Martha M. Eliot, Washington, D. C, John P. Peters, New Haven,

Conn., Samuel J. Kopetzky and Frederic E. Elliott.——Drs. John L. Rice, health commissioner, and Stanley R. Woodruff, Jersey City, N. J., addressed the Harlem Medical Association March 1 on "The Role of the Private Physician in Public Health" and "Management of Stones in the Urinary Tract" respectively.——Dr. Herbert Willy Meyer addressed the New York Surgical Society March 1 on "Perforations of the Gastrointestinal Tract."——Dr. Louis Lichtenstein addressed the New York Pathological Society February 23 on "Pathologic Findings Following Therapeutic Hyperthermia" and Drs. Abraham Penner and Alice Bernheim, "Hemostatic Mechanisms as a Cause of Visceral Lesions."——A symposium on arthritis was presented at a stated meeting of the New York Academy of Medicine March 2 by Drs. Philip S. Hench, Rochester, Minn.; Walter Bauer, Boston, and Ralph H. Boots, New York.——Dr. J. Irving Kushner, among others, addressed the Bronx Gynecological and Obstetrical Society February 27 on "Obstetrics in a General Hospital (10,000 Cases at the Bronx Hospital)."

NORTH CAROLINA

Society News.—Dr. Walter R. Johnson, Asheville, addressed the Buncombe County Medical Society, Asheville, March 20, on "The Use of the Gastroscope in Diagnosis of Stomach Disorders." Dr. James P. Rousseau, Winston-Salem, addressed the society in Asheville February 20 on "Roentgen Treatment of Pneumonia." In the afternoon the society held a panel discussion of pneumonia.——At a meeting of the Scotland County Medical Society in Laurinburg January 19 the speakers were Drs. Douglas Jennings, Bennettsville, S. C., on obstetrics; William T. Rainey, Fayetteville, on congestive heart failure, and William D. James, Hamlet, on the work of the state board of medical examiners.——Dr. Russell L. Haden, Cleveland, addressed the New Hanover County Medical Society, Wrightsville Beach, February 27 on "Nutritional Deficiency Diseases."

OHIO

Annual Library Meeting.—Dr. Cyrus C. Sturgis, Ann Arbor, Mich., addressed the second annual meeting of the Harold Brittingham Memorial Library at the Cleveland City Hospital January 17. His subject was "The Historical Development of Knowledge Concerning Blood Transfusion and Appraisal of Its Value." The library now contains 1,300 bound volumes and 500 books, it was reported. During 1938 4,800 visitors were registered and 1,500 items were borrowed.

Society News.—Dr. Arthur U. Desjardins, Rochester, Minn., addressed the Academy of Medicine of Cincinnati March 21 on "Radiotherapy for Inflammatory and Malignant Conditions." Dr. Herman O. Mosenthal, New York, discussed "Experiences with Protamine Zinc Insulin" March 7.——Dr. Grover C. Penberthy, Detroit, addressed the Montgomery County Medical Society, Dayton, March 17 on "Burns, Their Treatment and Management."——Dr. George M. Curtis, Columbus, addressed the Mahoning County Medical Society, Youngstown, March 21 on "Iodine Metabolism in Thyroid Disease."

OREGON

Society News.—A discussion of thrombosis and embolism was presented before the Multnomah County Medical Society, Portland, March 15 by Drs. Charles H. Manlove, Warren C. Hunter and Herbert H. Foskett.——Dr. Virgil E. Dudman, Portland, addressed the Central Willamette Medical Society, Eugene, February 2 on "Obstetrics: Emergency Conditions."

Changes in Health Officers.—Dr. Courtney M. Smith, Oregon City, has resigned as health officer of Clackamas County to become assistant health officer of Portland. Dr. Daniel P. Trullinger, Oregon City, succeeded Dr. Smith in Clackamas County.——Dr. Gerald E. Stark, Coquille, has been appointed health officer of Coos County to succeed Dr. Charles L. Coyle, Grants Pass, who resigned recently.

PENNSYLVANIA

Professor Krogh Lectures at Swarthmore.—Prof. August Krogh of the University of Copenhagen, Denmark, is delivering a series of lectures at Swarthmore College, Swarthmore. The general subject of the series is "The Comparative Physiology of Respiratory Mechanisms."

Personal.—Dr. Howard C. Frontz, Huntingdon, was recently elected to serve his second term as president of the Huntingdon County Medical Society; his first election was in 1897.——Dr. Thomas H. A. Stites, Nazareth, has been appointed medical director of the Cresson Sanatorium, State, a position he held from 1923 to 1935. He succeeds Dr. Louis A. Wesner.——Dr. Samuel J. Dickey, West Chester, health officer of Chester County, has been appointed director of the division of tuberculosis in the state department of health.

Philadelphia

Scarlet Fever Outbreaks.—Eighty-four students at Girard College were reported ill of scarlet fever March 24. Dick tests were to be made of the other 1,646 students.——The Sigma Phi Epsilon fraternity house at Temple University was quarantined March 21 when four of twenty-one residents became ill of scarlet fever.

Society News.—Drs. Manuel M. Pearson and Marcus David Burnstine, among others, addressed the Philadelphia Psychiatric Society March 10 on "Psychosis Precipitated by Sulfanilamide."——Among the speakers at a meeting of the Philadelphia Academy of Surgery March 6 were Drs. John S. Lockwood and Virgil H. Moon on "Bacteriologic Considerations in Wound Healing" and "Early Recognition of Shock and Its Differentiation from Hemorrhage," respectively.——At a meeting of the Philadelphia Laryngological Society March 7 the speakers included Drs. Matthew S. Ersner on treatment of type III pneumococcus meningitis with sulfapyridine; David Myers, treatment of otitic sepsis and meningitis with sulfanilamide, and Merrill B. Hayes, employment of sulfanilyl aminopyridine in other otorhinologic conditions.——Speakers before the Philadelphia County Medical Society March 8 were Drs. Samuel W. Sappington on "Heparin in Blood Transfusion"; Charles B. Hollis, "Effect of Tobacco on the Respiratory Tract," and George D. Geckeler, "Coronary Artery Disease."

RHODE ISLAND

Committee on Industrial Health Appointed.—Dr. Charles F. Gormly, Providence, has been appointed chairman of a committee on industrial health of the Rhode Island Medical Society. The appointment of the committee was authorized at a meeting of the house of delegates in January.

SOUTH DAKOTA

Dr. Cook Appointed State Health Superintendent.—Dr. John F. D. Cook, Langford, for many years secretary of the South Dakota State Medical Association, has been appointed superintendent of the state board of health. He succeeds Dr. Park B. Jenkins, Pierre.

TEXAS

Hospitals Opened.—The Patterson Memorial Hospital, Troup, was opened recently. The new eighteen room hospital was built by Miss Gillie Patterson, Troup, in memory of her parents. The Littlefield Hospital and Clinic, with twenty-three private rooms, two wards of two beds each and five bassinets, was opened recently.

Bequest to Sealy Hospital.—Mrs. Jennie Sealy Smith, who died Oct. 10, 1938, directed in her will that after the payment of certain bequests the balance of her estate, estimated at $4,000,000, be paid to the Sealy and Smith Foundation for the John Sealy Hospital, Galveston. A private and semi-private pavilion is to be erected in memory of Mrs. Smith's husband, R. Waverly Smith.

VIRGINIA

Society News.—Drs. Edwin C. Hamblen, Durham, N. C., and Charles P. Mangum, Richmond, addressed the Danville-Pittsylvania Academy of Medicine March 14 on "Endocrine Disturbances and Present Day Endocrine Therapy" and "Pediatric Endocrinology" respectively.——Dr. Beverly C. Smith, New York, addressed the Roanoke Academy of Medicine February 6 on "Diagnosis and Treatment of Peripheral Vascular Diseases" and Dr. Henry Lee, Roanoke, on "Postoperative Thrombophlebitis."

State Society's Cancer Committee.—*The advisory committee to the Virginia Cancer Foundation, appointed recently by the president of the Medical Society of Virginia, has been enlarged and will now act as an advisory committee to the Women's Field Army of the American Society for the Control of Cancer, the cancer foundation and any other agencies seeking advice or endorsement on this subject. Dr. Edwin P. Lehman, Charlottesville, is chairman and the members are: Drs. Irl C. Riggin, Richmond, state health officer; Isaac A. Bigger, Richmond; Frederick M. Hodges, Richmond; Robert L. Payne, Norfolk; Richard P. Bell, Staunton, and Isaac C. Harrison, Danville. Dr. Hugh H. Trout, Roanoke, president-elect of the state society, and Dr. Alexander F. Robertson Jr., Staunton, president, are ex officio members.*

WASHINGTON

Puget Sound Surgical Meeting.—Dr. Philip D. Wilson, New York, was the guest speaker at the annual meeting of the Puget Sound Surgical Society in Seattle March 10-11. Dr. Wilson delivered an address March 10 at a dinner at the Rainier Club on "Pioneers in Orthopedic Surgery." Saturday he conducted clinics at King County Hospital and in the evening spoke at the annual banquet on "Inequality of Leg Length and Methods of Correction."

Society News.—Dr. Brien T. King, Seattle, addressed the Walla Walla Valley Medical Society, Walla Walla, February 9 on goiter and on recent research on the restoration of the abductor function of the larynx following paralysis due to recurrent nerve paralysis.——A symposium on the biliary tract was presented before the King County Medical Society, Seattle, March 6, by Drs. Clyde R. Jensen, Thomas W. Blake, Charles E. Watts and John A. Duncan.——Dr. Sterling Bunnell, San Francisco, was the guest speaker at the annual meeting of the Tacoma Surgical Club April 1. His subject was "Primary Repair of the Injured Hand."——A symposium on gallbladder disease was presented before the Spokane County Medical Society, Spokane, March 16 by Drs. James M. Nelson, Joseph Melvin Aspray, Charles M. N. Anderson, Robert L. Rotchford and Rudolph G. Andres.——Drs. Samuel E. Light and John W. Gullikson addressed the Pierce County Medical Society, Tacoma, February 14 on "Treatment of Acne Vulgaris" and "Spinal Anesthesia" respectively.

WYOMING

Personal.—Dr. Walter M. Lacey, Cheyenne, has resigned from the state board of medical examiners and has been succeeded by Dr. Jacob R. Pierce, Thermopolis.

Changes in State Board of Health.—Dr. Enos G. Denison, Sheridan, and Raymond G. Howe, D.D.S., Casper, have been appointed members of the state board of health and Dr. Marshall C. Keith, Casper, has been made state health officer. Dr. Keith is secretary of the Wyoming State Medical Society.

GENERAL

Nurses Wanted for Latin American Service.—At the request of health authorities of one of the Latin American republics, the Pan American Sanitary Bureau, Washington, D. C., is seeking nurses familiar with Spanish and if possible trained in care of mental cases. Contracts will be offered for two years and transportation to their destination will be paid.

The Society of University Surgeons.—This society, organized in 1938, held its first annual meeting at the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., in February. Dr. Samuel J. Stabins, Rochester, was elected president; Dr. Warren H. Cole, Chicago, president-elect, and Dr. Frank Glenn, New York, secretary. The society is made up of surgeons who have completed a surgical residency in one of the following schools and are now engaged in teaching in these or other institutions: University of Chicago, University of Cincinnati, University of Rochester, Columbia, Cornell, Harvard, Johns Hopkins, Vanderbilt, Washington and Yale universities.

Changes in Status of Licensure.—The State Board of Health of Kentucky has reported the following action:

Dr. Ernest Raspberry Alexander, Cynthiana, license revoked January 7 for violation of the Harrison Narcotic Act.

Dr. Walker L. Stumbo, Lackey, license revoked January 7; allowed to practice on probation.

The New York State Board of Medical Examiners reports the following action:

Dr. Edmund K. Macomber, 745 New Scotland Avenue, Albany, license revoked Nov. 16, 1938, for criminal abortion.

The Virginia State Board of Medical Examiners recently reported the following action:

Dr. J. Burton Nowlin, Lynchburg, license revoked Dec. 14, 1938, for violations of the Harrison Narcotic Act.

Dr. Gilmer Rosser Shelton, Dabney, license revoked Dec. 14, 1938, on account of violations of parole in relation to the Harrison Narcotic Act.

Society News.—The annual convention of the American Red Cross will be held in Washington, D. C., April 24-27.——The twenty-fourth annual meeting of the American Association of Industrial Physicians and Surgeons with the American Conference on Occupational Diseases and Industrial Hygiene will be held at the Hotel Statler, Cleveland, June 5-8.——The American Society of Anesthetists will meet in New York April 14 with the following speakers: Drs. Philip D. Woodbridge, Boston, and Karl A. Connell, Branch, N. Y., on "Hazards of Explosion from the Point of View of the Anesthetist," and Joseph Warren Horton, Sc.D., Cambridge, Mass., "Factors Affecting the Occurrence and Prevention of Electrostatic Sparks."

Bequests and Donations.—The following bequests and donations have recently been announced:

St. Joseph's Hospital, Syracuse, N. Y., $147,932.93 by the will of the late George Doheny. Other institutions sharing equally in the residuary estate include the Syracuse Memorial Hospital, General Hospital of Syracuse, Syracuse Free Dispensary and St. Mary's Maternity Hospital and Infants' Asylum.

Lenox Hill Hospital and New York Post-Graduate Medical School and Hospital, $20,000 each, and New York Infirmary for Women and Children, $15,000, by the will of Mrs. Amalia F. Morse; all are in New York.

Lenox Hill Hospital, New York, $150,000 by the will of the late Jacob Ruppert.

Eye and Ear Hospital of Pittsburgh, $3,000 by the will of Dr. James A. Lippincott.

St. Luke's Hospital, New York, $5,000, and New York Eye and Ear Infirmary, $2,500 by the will of Miss Virginia Scott Hoyt.

Methodist Episcopal Hospital and Methodist Home for the Aged, Philadelphia, $5,000 by the will of the late Miss Emily Leaming Goble.

Shriners Hospital for Crippled Children and Lankenau Hospital, Philadelphia, will share with three other institutions about $600,000 from the estate of the late C. Henry Strecker.

Special Society Elections.—Dr. James L. Dunavant, Ripley, Tenn., was chosen president-elect of the Mid-South Post Graduate Medical Assembly at the annual meeting in Memphis, Tenn., in February. Dr. Herbert Fay H. Jones, Little Rock, became president.——Dr. Charles J. Andrews, Norfolk, was named president-elect of the Tri-State Medical Association of the Carolinas and Virginia at the annual meeting in Charleston, S. C., in February. Vice presidents elected were Drs. John S. Horsley, Richmond, Va.; Harold S. Clark, Asheville, N. C., and William R. Wallace, Chester, S. C. Dr. James M. Northington, Charlotte, N. C., was reelected secretary. The 1940 meeting will be in Richmond.——Dr. Robert D. Schrock, Omaha, was chosen president-elect of the American Academy of Orthopaedic Surgeons at its seventh annual convention in Memphis January 15-19, and Dr. George E. Bennett, Baltimore, was installed as president. Other officers are Drs. Alfred R. Shands Jr., Wilmington, Del., vice president; Eugene Bishop Mumford, Indianapolis, treasurer; Carl E. Badgley, Ann Arbor, Mich., secretary, and Philip Lewin, Chicago, historian and librarian. The next annual session will be held at the Hotel Statler, Boston.

Meeting of American Rheumatism Association.—The American Rheumatism Association will hold its annual meeting in St. Louis May 15 at the Chase Hotel, beginning at 9:15 a. m. All members of the American Medical Association are invited. Following the presidential address by Dr. Ralph Pemberton, Philadelphia, the program will be presented:

Dr. Francis C. Hall, Boston, Menopause Arthritis.

Dr. Richard H. Freyberg, Walter D. Block, Ph.D., and M. F. Fromer, Ann Arbor, Mich., Study of Sulfur Metabolism and the Effect of Sulfur Administration in Rheumatoid Arthritis.

Dr. Louis Maxwell Lockie and Roger S. Hubbard, Ph.D., Buffalo, Observations of Effect of High Fat Diet in Gouty Arthritis.

Dr. J. Albert Key, St. Louis, Foreign Body Arthritis.

Drs. Marian W. Ropes and Walter Bauer, Boston, Origin and Nature of Normal Synovial Fluid.

Drs. Martin Henry Dawson and Ralph H. Boots, New York, Arthritis Associated with Lymphogranuloma Venereum.

Drs. Frances Baker, James F. Rinehart, Stacy R. Mettler and Frederick S. Bruckman, San Francisco, Rheumatoid Arthritis of the Spine.

Drs. Nathan Sidel and Maurice I. Abrams, Boston, Treatment of Chronic Arthritis: Results with Saline Injections Used as Controls for Vaccine Therapy.

Dr. John P. Stump, New York, Prevention of Arthritic Deformities by Early Orthopedic Management.

Report of the Commonwealth Fund.—During its twentieth year the Commonwealth Fund of New York appropriated $2,277,953.19 for philanthropic purposes. More than four fifths of its expenditures went for the promotion of health, principally for medical education, research, public health and community hospitals in rural areas. The fund's endowment having been raised in 1937 to almost $50,000,000, the appropriations for the past year were the largest it has ever made. The ninth rural hospital built by the fund was opened at Ada, Okla., during the year, and two others have been planned—one at Provo, Utah, and one at Lancaster, S. C. A new type of arrangement has been made with the Kings Mountain Memorial Hospital at Bristol, Tenn.-Va., by which the fund will finance modernization of the plant and provide resident medical service. In return, the community agrees to put the institution on a sound financial footing and bring its operation in line with accepted standards. Contributions to medical education through various channels amounted to $375,000. A new plan in this field was to award fellowships to ten junior instructors

in medical schools for study in other institutions. Four junior staff men interested in pediatrics received fellowships to study psychiatry. Other new awards include subsidies to the departments of preventive medicine at New York and Long Island College of Medicine. Fifteen medical schools and hospitals received funds for medical research amounting to $345,000. To some extent these funds were concentrated on groups of related studies at different centers. Oklahoma and Alabama were added this year to the states receiving assistance in support of rural public health service. In Oklahoma a state traveling unit to advise local health officers and a demonstration of county health work in Seminole County were made possible through the fund. In Alabama the state health department received aid in building up a health district of seven counties as a means of strengthening local service in various fields of local health activity. One of the major interests of the Commonwealth Fund is in mental hygiene and it has promoted this activity in England as well as in the United States. According to the report, these activities in the United States have three main objectives: to encourage exploration of the frontiers between psychiatry and other areas of medicine (particularly pediatrics); to increase the supply of trained psychiatrists and psychiatric social workers, and to promote and safeguard standards of clinical organization and service. The fund last year subsidized teaching clinics at the New York Hospital and the Babies Hospital in New York, Children's Hospital in Boston and the University of Minnesota, Minneapolis; it offered fellowships in psychiatry and psychiatric social work and maintained a national advisory service for community clinics in cooperation with the National Committee for Mental Hygiene. In England the fund continues to assist the London Child Guidance Center, an agency known as the Child Guidance Council and a training course for psychiatric social workers.

CANADA

Society News.—Dr. Edmund L. Keeney, Baltimore, addressed the section on medicine of the Academy of Medicine of Toronto January 10 on "'Slow' Epinephrine" and Dr. Alfred H. W. Caulfield on "'Slow' Epinephrine Inhalant."—— Dr. Irvine McQuarrie, professor and head of the department of pediatrics, University of Minnesota Medical School, Minneapolis, addressed the Montreal Neurological Society at McGill University, Montreal, March 1, on "Physicochemical Studies on the Mechanism of Convulsive Phenomena."

Grants to University of Toronto.—A gift of $250,000 from the Rockefeller Foundation toward an endowment for the school of nursing is announced by the University of Toronto. The department of medical research at the Banting Institute has received from the Supreme Council of the Scottish Rite Masons a grant of $2,500 for research on the insulin and metrazol treatments for dementia praecox. A gift of 200 mg. of radium has been made to the department of medical research by Gilbert A. Labine of the Eldorado radium mines in memory of his son Leonard.

FOREIGN

Dr. Rous Lectures in England.—Dr. Francis Peyton Rous of the Rockefeller Institute for Medical Research, New York, gave the William Withering Lectures at the University of Birmingham, England, March 9, 16, 21 and 23, on the cancer problem.

Anniversary of Petrus Camper's Death.—The University of Groningen, Holland, announces a special meeting and exhibition April 29-30 to commemorate the one hundred and fiftieth anniversary of the death of Petrus Camper, a physician, anatomist, obstetrician and artist who for ten years was professor of medicine at the university. Camper died April 7, 1789. At the memorial meeting Saturday evening, April 29, addresses will be made by Dr. B. W. Th. Nuyens, Amsterdam, and members of the Groningen faculty. The exhibition will bring together anatomic drawings by Camper and a number of preparations made by him. The drawings are in the possession of the Library of the Netherlands Society for the Promotion of Medicine at Amsterdam and the University Library at Leyden.

CORRECTION

Immunization Against Pertussis.—In Miller and Faber's article in THE JOURNAL, March 25, page 1147, second column, first paragraph, line seven, the word "disease" should have been "exposure" and in the following line the word "from" should be deleted. In the second line of the third paragraph in the same column the word "atypical" should be "typical."

Government Services

Meningitis on the Navajo Reservation

An outbreak of meningitis on the Navajo Indian Reservation, which covers parts of Arizona, New Mexico, Colorado and Utah, is reported in a recent issue of the *Navajo Medical News*, bulletin of the Indian Medical Service for this reservation. The report covered the area served by the Indian Hospital at Shiprock, N. M. In twenty-seven suspected cases, the diagnosis was positive in thirteen, presumptive in twelve and negative in two. Twenty-six cases occurred in Navajos. Several of the patients had died before the physicians were notified and the diagnosis was made from descriptions of the symptoms. Of the twenty patients who were hospitalized, nineteen were in Shiprock hospital. There were thirteen deaths: five in the Shiprock hospital; one in San Juan Hospital, Farmington, N. M., and seven outside of hospitals. Most of the patients were children, the average age being 11½ years. A brief mention of this outbreak, based on a newspaper report, was published in THE JOURNAL January 28 under Utah news, page 343.

Medical Activities of the Veterans' Administration

The Veterans' Administration had 50,899 patients under hospital care at the close of the fiscal year ended June 30, 1938, an increase of 4,483 over the previous year, according to the annual report of the administrator. The largest proportion of these beneficiaries were hospitalized for neuropsychiatric diseases, 57.54 per cent; 9.64 per cent were under treatment for tuberculosis and 32.82 for general medical and surgical conditions. Of the total number of veterans, 76.32 per cent were receiving treatment for disabilities not of service origin.

Hospital admissions for 1938 were the highest of any fiscal year since 1919, when government facilities were authorized for care of World War veterans. There were 152,966, of which 91 per cent were for nonservice-connected disabilities. They were divided as follows: 10,989 for tuberculosis, 10,750 for psychotic or mental diseases, 12,686 for other neurologic disorders and 118,541 for general medical and surgical diseases.

During the fiscal year 202,081 patients were under treatment; 149,956 were discharged after an average of 76.9 inpatient days. Deaths in hospitals totaled 10,117, or 6.75 per cent of the discharges. Of the total number of deaths, 6,620 occurred among patients with general conditions; about 36 per cent of these deaths were caused by diseases of the circulatory system including heart disease, and 33 per cent by malignant tumors and diseases of the digestive system. In addition, there were 1,979, or 19.56 per cent of all the deaths, from pulmonary tuberculosis, and 1,518, or 15 per cent of the total, from neuropsychiatric diseases.

Veterans present in domiciliary status in facilities under the control and jurisdiction of the administration totaled 14,254, an increase of 3,216 during this fiscal period. Of the entire number, 10,104 were disabled by medical and surgical conditions, 3,844 by neuropsychiatric diseases and 306 by tuberculosis. During the year there were 28,585 admissions for domiciliary care, of which about 90 per cent were for nonservice-connected disabilities.

The Veterans' Administration was operating hospital facilities at eighty-one locations in forty-three states and the District of Columbia, with a capacity of 51,991 beds. There was an increase of 4,570 beds, of which 80 per cent was in beds for mental patients. At the close of the fiscal year construction was in progress on twenty-two major projects to provide 3,626 beds. Funds have been made available for 6,593 more beds. The administration also has 16,798 domiciliary beds and new construction will provide 2,158 more.

The net operating expense for all facilities totaled $49,076,115.42 and the per diem rate for the year was $2.65, as compared with $2.81 in 1937.

Field facilities of the administration made a total of 1,128,587 physical examinations for outpatient purposes, of which 98 per cent were medical and 2 per cent dental. Treatments furnished during the year totaled 994,968, as compared with 895,208 the previous year. About $400,000 was authorized for the purchase of orthopedic and prosthetic appliances, the largest item being $122,000 for artificial legs.

The Protection of Physicians in Air Raids

In a debate in the House of Lords on air raid shelters, Lord Horder said that in the event of war no adequate security, physical or moral, could be afforded to those who continued to work in a dangerous area, except by some form of bomb-proof shelter. He had special reason for speaking, because one body must inevitably work in a danger zone—the physicians. An intensive air raid must paralyze for a time all activity, even on the part of physicians at a first aid station. Some thought that as many casualties as possible should be removed forthwith from the danger center to the less dangerous parts of the city, the periphery. But, owing to the congestion of thoroughfares and the blocking of streets by débris, many casualties would have to be treated at the point of origin and the physicians must be there to administer treatment. This was the whole meaning of a first aid station or hospital. He therefore entered a special plea that the first aid stations must be in some bomb proof place, and he could think of none adequate for this purpose except a deep underground shelter. At present 95 per cent of physicians were already enrolled by the British Medical Association for war work. The minister of health was now earmarking from that register those for special purposes. The number of these experts was limited, and the first air raids must count among their casualties a large number of physicians. He was not speaking on their behalf; he was speaking economically. They were valuable citizens and more valuable prospectively in the event of war. Their replacement was limited and, apart from that, their work would be possible only underground. Not only they but their valuable equipment, which would be difficult to replace in an emergency, must be in a place of adequate shelter. Replying for the government, Lord Birkenhead said that the question of underground dressing stations was under consideration. The problem of deep shelters was more complex than was supposed. None of the continental great powers had gone in for them on a large scale.

A Clinic for Criminals

That crime is often a medical problem has been increasingly realized in recent years. Dr. Norwood East, lecturer on crime and insanity at the Maudsley Hospital, and Dr. W. H. Hubert, psychotherapist at Wormwood Scrubs Prison, have in their official report recommended a new institution in which abnormal and unusual types of criminals can be given psychologic treatment. They have for four years been engaged in an investigation to determine how far psychiatric and psychotherapeutic experience in the management and treatment of psychotic and psychoneurotic illnesses and various forms of behavior could be applied with profit to prisoners of divergent types.

They investigated 406 prisoners, including boys with whom the Borstal system had failed, adolescent adults and a large group of sex offenders. Of these, 214 were treated psychologically. They concluded that 75 per cent of the Borstal boys, 55 per cent of the adolescents, 30 per cent of the adults and from 30 to 65 per cent of the sex offenders were suitable for the new institution. They suggest that this should serve as (1) a clinic and hospital for treatment by psychotherapy, (2) an institution for the psychiatric treatment of prisoners who have not proved amenable to the reeducative and rehabilitating influences of the modern prison, (3) a colony for offenders for whom reformative methods, however specialized, seem useless and the severity and hardships of prison life are not appropriate, and (4) an observation and treatment center for boys who, because of mental abnormality, appear unsuitable for Borstal training or have failed to respond to it. The medical staff should be psychiatrically trained, with additional experience in criminology, and the superintendent should be a prison psychiatrist. The inmates should not be insane or mentally defective and should not be encouraged to regard themselves as irresponsible mental invalids. Those who refuse to cooperate in treatment and abuse their privileges should be returned to prison.

Other recommendations of the report are extension of the use of psychotherapy on probation, but largely confined to first offenders, with the condition that the offender must reside for certain periods in a mental hospital or approved place. The investigation was confined to men and boys, but the investigators do not doubt that their experience justifies the appointment of a woman psychotherapist to a woman's prison and they recommend such an appointment.

Protamine Zinc Insulin in the Treatment of Diabetes

At the January 20 meeting of the Société médicale des hôpitaux of Paris, Dr. Raoul Boulin reported the following results of treatment with protamine zinc insulin in 100 cases of diabetes:

1. Glycosuria disappeared in seventy-four cases. In two of these, injections of ordinary insulin had also been given before meals. In the other seventy-two the glycosuria could be controlled with a dose of protamine zinc insulin which was only one sixth that of ordinary insulin. In eleven of the other twenty-six cases the blood sugar content was lowered about 50 per cent, but in fourteen cases the substitution of protamine zinc insulin failed to have any influence on the glycosuria. In the last-named group the diabetes was of a severe type, from 70 to 90 units daily of ordinary insulin being required to control the glycosuria. A better result might have been obtained in these fourteen cases if ordinary insulin had been given as an adjuvant before meals.

2. The blood sugar content before eating was brought down to normal in twenty-eight cases with doses of protamine zinc insulin varying from 16 to 50 units, about one fifth the dose of ordinary insulin. Of the other seventy-two cases, the blood sugar content was slightly above normal, i. e. from 1.25 to 1.5 Gm., in twenty-nine, between 1.5 and 2 Gm. in twenty-nine and above 2 Gm. in fourteen. In a total of ninety-six cases there was a lowering of the blood sugar content before eating, even though there was an average reduction of one sixth from the dose which, with ordinary insulin, would have given the same results. In four cases of severe diabetes the blood sugar content was distinctly higher after the use of protamine zinc insulin.

3. Local complications noted were painful nodules at the site of injection, which became ecchymotic at times. Such nodules were usually observed if the injections of protamine zinc insulin had been given too superficially. In addition to these nodules, pruritus, urticaria and a bullous eruption were seen. These local complications necessitated cessation of treatment in two cases.

4. General complications included in two cases headache so severe as to cause the treatment to be suspended. Symptoms of hypoglycemia were observed in nineteen cases. The syndrome usually appeared after midnight, in the milder form as nausea and profuse perspiration. In only four cases were convulsions and a comatose state noted, and response to treatment was rapid.

5. A sudden transitory increase in the severity of the glycosuria or a sudden drop in the blood sugar content, also temporary, was often noted.

6. An apparent failure to obtain good results with protamine zinc insulin is often due to the fact that the patient does not shake the ampule so that the insulin is well suspended in the solution. Other causes of failure which may be cited are injection into the muscular tissues instead of the skin and a too liberal diet.

7. Protamine zinc insulin is to be especially recommended for diabetes of moderate severity. In a certain number of cases of severe diabetes it has the advantage over ordinary insulin that it can be given not only in smaller doses but also in a single injection. In other cases of severe involvement, about 14 per cent of all in which ordinary insulin is indicated, the protamine zinc combination given alone and in a single dose has not given as good results as ordinary insulin given in several doses; hence it is advisable to employ both the ordinary and the protamine zinc variety.

Cerebral Complications Following the Use of Acetarsone

At the January 20 meeting of the Société médicale des hôpitaux of Paris a case was reported by Dr. Robert Worms in which cerebral symptoms appeared a few hours after introduction into the vagina of a tablet containing 0.25 Gm. of acetarsone. A woman aged 65 had been given such tablets as a remedy for leukorrhea. The treatment was resumed after a lapse of three months. About twelve hours after insertion of a tablet she felt nauseated and complained of a severe headache and the temperature rose to 103 F. The following day a generalized scarlatiniform eruption appeared. Despite repeated injections of epinephrine the headache became more severe, and forty hours later the patient became comatose after an epileptiform convulsion. The coma persisted for two days and was followed by rapid cessation of all symptoms. In a search for the cause of such a clinical picture it was found that twelve years before the patient had been given a series of injections of acetylarsan (a French proprietary preparation, p-oxy-acetylamino-phenylarsinate of diethylamine) for chronic intestinal parasitosis. Five days after the second injection severe headache, convulsions and coma appeared, which receded as rapidly as during the present attack.

Dr. Worms expressed the opinion that, as in the case reported by Laederich and his co-workers, the syndrome following the introduction into the vagina of such a relatively small amount of an arsenical preparation could be due only to an intolerance to such medication.

In the discussion the syphilologist Dr. Milian said that the pentavalent arsenical preparations so commonly employed at present are apt to give rise to the same complications as the trivalent arsenical preparations. The use of the pentavalent preparations can be followed by peripheral neuritis or neuritis involving the optic or auditory nerve in persons who have an intolerance toward all arsenical preparations. As to absorption from the vagina, in the use of arsenical preparations for syphilis, he had seen results from the use of vaginal suppositories as good as those which are generally obtained with oral or intravenous medication.

The New Medical Curriculum

The increased shortage of trained professional men in Germany has aroused a great deal of apprehension with regard to the younger generation. Certainly the educational programs have numerous disadvantages, the most egregious of which have been the late age at which training is completed and the still later age at which the professional man has found it possible to establish a family. Legislation to become effective April 1 has been framed with the purpose of correcting these disadvantages. The new law aims chiefly at a greater concentration of the curriculum and the avoidance of unnecessary waste of time. Revisions become necessary in the medical curriculum from time to time in order that the schools may keep pace with the advances of scientific knowledge; certain courses lose their importance and new courses of study must be accorded a larger place. Since the Nazi revolution, a whole series of reforms has been urged. The physician now is quite mature before he founds a family. The prospective doctor passes the examination for entrance to the university at the age of 18 (the earliest limit). At the age of 20 or 21 he has completed the compulsory labor service and military service required of all male citizens. There follow five and one half years of medical study and the year of undergraduate internship required of every medical student before he receives the final license. Meanwhile the young man has reached the age of 27 at least. If he wishes to specialize there follows a further period of special training, which averages five years. Most doctors are ultimately admitted to sickness insurance practice, but before becoming a panel practitioner a doctor must have had at least two years of general practice. Time spent in the study of a specialty is to a certain extent deductible from the period of preparation for panel practice. Accordingly a general practitioner is about 29 and a specialist about 33 before an independent practice can be begun.

The curtailment effected by the new legislation will amount to two years; it is accomplished as follows: 1. The regular curriculum is reduced from the present eleven to ten semesters (four preclinical and six clinical). 2. The year of internship, which at present must be served immediately after the student has completed his courses and passed the state examination, is incorporated within the undergraduate schedule. At specified times the medical student will serve under a staff physician as a "famulus" in a clinic or hospital. This arrangement has existed for decades on a voluntary basis. Hospitals must now adjust their routines to this new compulsory arrangement, which at the same time deprives them of the services of the graduate interns. For many institutions this loss of the "praktikanten" will be a severe blow since these men receive no remuneration and often perform valuable service. 3. Another half year will be saved by drastic abbreviation of the time required for taking the state examinations.

Despite these curtailments, several new compulsory lecture courses have been introduced into the curriculum at the instance of the national führer of physicians and the national führer of university instructors. According to official explanation of the innovation, "it must no longer be optional with the student whether or not he commits himself with regard to questions of vital importance to national life. The physician of the future must have an authoritative, fundamental knowledge of all these problems. In future less stress will be placed on the theoretical training than on the principle that theoretical knowledge and practical performance may be correlated in such a way that the present lack of practical ability will be a thing of the past." Whether through this new orientation

much will be lost that has helped to establish the reputation of German medicine the future will tell. The very foundations of this reputation may be menaced. Sad to say, the new curriculum represents a type of medical education the introduction of which has constantly been opposed by all intelligent medical groups. On the contrary, it cannot be denied that the reform legislation contains good points. For example, hereafter the courses in zoology, botany, chemistry and physics designed for medical students will be freed of a vast amount of detail which, while valuable to the student of natural science, is of no particular importance to the medical student. In the anatomy courses too the student will be spared certain excessive feats, such as the learning by heart of the nomenclature of the most minute vessels. Conversely, topographic anatomy will be given greater consideration.

The following items have been introduced into the preclinical curriculum: lectures on the history and nature of the art of healing, lecture courses in ethnology and policies regarding population (scheduled for the first semester, before the student can have formed any independent opinion with regard to these things), field trips in search of medicinal herbs, supplementary to the course in botany, six weeks of practice nursing (a real advance), a lecture course on the physiology of occupation, sports and aviation, and practical experience as a worker in a factory or on a farm. The excursions in search of medicinal herbs will of course further the new movements for natural therapeutics. The nursing service is to be performed between the second and third semesters; it is to show whether the student is psychically equal to contacts with the sick and whether or not he should continue in medicine. Factory service or farm service, lasting four weeks, will be interposed between the third and fourth semester. This means actual work as a farm or a factory hand; the requirement was initiated by public health headquarters of the Nazi party and is designed to aid the future practitioner to a better understanding of popular needs.

To the clinical part of the curriculum have been added courses in radiology, natural therapeutics, occupational diseases, treatment of traumatic injuries, child welfare, eugenics, dental diseases, genetics, forensic medicine and deontology. Several shorter lecture courses have been added and finally two three month terms as a famulus (between the sixth and seventh and the eighth and ninth semesters).

In professional quarters fears have been entertained that training under the new curriculum will be less complete than under the present curriculum. On the other hand, it is expected that the new plan will be "much more in accord with practical needs" and "more realistic." Henceforward the German medical student must work extra hard to assimilate his courses within a brief period. But it is already apparent that this high pressure type of training is being overdone and that the spirit of medical science, which ought to prevail, stands in danger of being badly damaged by overorganized curricular schedules. The youthful student should be allowed time in which to reflect on all the new facts learned in his courses and to make these an intimate part of himself. To do so he must have vacations and leisure periods, both of which are to be taken from him. Now he will be turned into a learning robot, hurried from one task to another.

There is no doubt that the lack of doctors must be made up as quickly as possible. Similarly a few weeks ago the prescribed minimal curriculum in all institutes of technology and kindred schools was abbreviated because of a shortage of engineers and other trained technicians, which is even more acute than the shortage of physicians. Although the ministerial decree of course does not say so, it is obvious that gaps exist in the ranks of German physicians as a consequence of the exclusion of Jews from practice. The expansion of the defense forces has created an additional need for physicians for, without exception, besides the six months labor service, military service has to be taken for two years before the younger men can begin their medical studies. It will be several years before the new curricular reforms can exert perceptible influence on the serious shortage of doctors. Will the young physicians trained under a system that minimizes theoretical principles be able to carry the disciplines into the practice of medicine, as doctors have been wont to do? Will the doctors of the future be able to find their way among new phenomena and principles no mention of which was made in their studies, and will they be able to comprehend the unfamiliar? There is room for doubt. Is it possible that the imponderabilities are being irretrievably sacrificed to temporary political expediency?

AUSTRALIA

(From Our Regular Correspondent)

Feb. 14, 1939.

National Health Insurance Abandoned

The commonwealth government of Australia has now decided to abandon completely its scheme for national health and pensions insurance. In a determined effort to preserve the plan even if only in skeleton form, several alternative schemes less comprehensive in nature were considered, but the agreement to abandon the whole insurance act was reached today with only two members dissenting. The treasurer (Mr. R. G. Casey), who evolved the scheme and fathered it through parliament, has now emerged as one of the strongest advocates against it. Reasons advanced for this decision are fear that the financial burden involved may be so great as to stifle normal developmental expenditure if it is allowed to fall simultaneously with the heavy defense program to which the ministry is already committed, fear of the repercussions from the cost of insurance while the greater part of the commonwealth is suffering from the effects of severe drought and widespread bush fires, and a recognition of the fact that throughout Australia the act is highly unpopular and that its introduction against the wishes of the people may lead ultimately to grave political consequences.

The opposition to the scheme in the ministry itself, although strong when parliament adjourned in December, has increased immensely since. In the past two months, members of the cabinet have moved freely in their electorates and have in many cases been astonished at the intensity of public feeling against national insurance.

The abandonment of the scheme will cost the commonwealth government at least £750,000 and perhaps £1,000,000, according to estimates made by the National Insurance Commission. Large sums of money have been spent on the initial steps for its establishment and numerous "approved societies" have incurred heavy expenditures to cope with the new responsibilities which they were prepared to undertake. Already 156 such societies have been formed in Australia, sixty by trade unions, fifty-nine by friendly societies and thirty-seven by miscellaneous organizations; wages contracts have been entered into with staffs, and many men have left lucrative posts to take administrative positions with the government or with approved societies. The government has not yet considered whether the whole organization which it created will be disbanded immediately or whether it will be kept to form a nucleus for the proposed national register (for defense purposes). The British Medical Association in Australia has been opposed from the start to national insurance as proposed by the government. It is to be hoped that this abandonment of the present scheme will furnish an opportunity for drawing

up at some future date a scheme more universally acceptable, to be put into practice at a time when the nation is better prepared to handle developmental measures.

The Future of Pharmacy

That the future of pharmacy depends on its resuming its original primary function as handmaiden to medicine was the theme of an address by Sir Stanton Hicks, professor of physiology at Adelaide University, to the pharmaceutic section of the recent meeting of the Australian and New Zealand Association for the Advancement of Science. Recent advances in synthetic aids to therapy demand the application of expert chemical knowledge in the medical field, but the physician in his capacity as a practitioner cannot be expected to grasp the full significance of the intricacies of chemistry. He needs cooperation with a chemical assistant, who will be able to advise him concerning the value of new synthetic therapeutic substances and other therapeutic chemical advances. Sir Stanton Hicks said that the profession of pharmacy must come back to where it was before the split between the apothecary and the physician. But we are coming back along roads which could not be envisaged then.

With the development of specific medicinal reagents, for example chemotherapeutic substances, vitamins, endocrine products and immune serums, we are approaching a phase of rational specific nonsurgical therapy, for which the whole-hearted cooperation of the pharmacist must be enlisted and for which the pharmacist must be prepared.

Regarding the need for chemical guidance in the doctor's choice of new therapeutic substances, it is doubtful that any individual pharmacist could give a reasonable opinion on their value. General opinion in Australia favors the formation of a body comparable to the Council on Pharmacy and Chemistry of the American Medical Association.

Medical Survey of Children

The possibility that many children acquire uneven shoulders because of the overuse of their right hand and arm was discussed by Dr. E. A. Machin before the recent congress of the Australian and New Zealand Association for the Advancement of Science. Dr. Machin disclosed the results of a health survey of 16,777 children attending state schools in New South Wales. Of the boys examined 34.2 per cent had uneven or "dropped" shoulders. Such shoulders appear to be associated with the general uneven or one-sided development of the muscles of the shoulder girdle as the result of the overuse of the right hand and arm. Games like tennis appeared to overemphasize the difference between the two sides.

Of the children examined 77 per cent had slight or no medical defects, 20.4 per cent had remediable defects including marked dental defects, 1.9 per cent had permanent defects not seriously incapacitating, and 0.4 per cent had defects causing permanent serious incapacity. The posture was reported as good for 26 per cent, average for 43 per cent, below average for 26 per cent and poor for 4 per cent. The nutrition of 37 per cent was good, of 64 per cent average, of 8.3 per cent below average and of 2.1 per cent poor. These figures, however, are based on a purely arbitrary standard of classification and are apt to convey a false impression as to the state of nutrition of Australian school children.

Postgraduate Education in New South Wales

This year is marked by the establishment of a postgraduate school of medicine at the Prince Henry Hospital in Sydney. This hospital, which was reconstituted by act of parliament in 1936, has been divided into three departments, of medicine, surgery and pathology, each under the control of a director, and, although a number of students have been attached to the school during the past year, attention has been devoted mainly to developing the organization necessary for postgraduate work. It will figure largely in the 1939 program of medical courses for graduates. Four important fellowships have been founded by the board of directors with the object of promoting postgraduate teaching in medicine and surgery in New South Wales, by enabling suitable graduates to obtain special experience in these fields, and also of encouraging and advancing research in medicine and surgery by systematized postgraduate instruction. A fellowship in anesthesia has been founded.

The New South Wales Postgraduate Committee holds a general revision course each year, which is brief and intensive and designed for general practitioners. Week end courses are held at various country centers; courses of a more special nature are arranged, and instruction for higher degrees and diplomas is provided.

Education for Physical Fitness

The coordinating Council of Physical Fitness at its recent meeting in Melbourne decided to ask the federal government to provide lectures in physical education at each of the Australian universities. The proposed scheme envisages a center in every state where young men and women may obtain instruction and training to qualify them for the instruction and training of others in physical fitness. In Australia there is a dearth of qualified persons in this field, and the primary task of any fitness campaign is to educate a team of potential instructors. The cost to the commonwealth government of the present proposals will be £12,000 a year. This will provide lecturers' salaries, the equipment of gymnasiums and the provision and upkeep of all facilities.

Oversupply of Medical Students

If the number of first year medical students at Australian universities remains constant, and there is every reason to assume that it will increase, one in every 250 young men and women in Australia will be embarking on a medical course. This proportion is absurdly high and must lead to an overloading of the medical profession. In comparison, one in 1,500 is entering the profession of dentistry, one in 600 the law and one in 800 engineering.

Money Spent on "Patent Medicines"

In an address on national health services at the seventh summer school of the Australian Institute of Political Sciences, Dr. T. L. Dunn, city health officer of Sydney, stated that the Australian public spends £11,000,000 annually on "patent medicines" and so-called cures. This represents an average annual expenditure of £2 a person.

Marriages

WESLEY DEE THOMPSON JR., Philadelphia, to Miss Catharine Gray Bennett of Wellsboro, Pa., Nov. 22, 1938.

HERBERT WILLIAM WALL, Los Angeles, to Mrs. Kathleen Petty Hudson in Dallas, Texas, in December 1938.

PRESTON HEPBURN WATTERS to Miss Mary Margaret Culbertson, both of Miami, Fla., in December 1938.

ARSHAK Y. YAZARIAN, Washburn, Ill., to Miss Satenig Siranossian of Bridgewater, Mass., August 14.

ST. JULIEN R. MURCHISON to Miss Lady Mildred Thomas, both of Fort Worth, Texas, Dec. 15, 1938.

RUSSELL C. WILLOUGHBY, Groves, Texas, to Miss Louise Latimer of Port Arthur, Oct. 12, 1938.

THOMAS B. TAYLOR, Douglasville, Ga., to Miss Carol Taylor at Powder Springs, in December 1938.

CHARLES STEPHEN WHELAN, Boston, to Miss Maria Elizabeth Hearns of Brooklyn, February 6.

LANDRUM TUCKER, Ripley, Tenn., to Miss Helen Roberts at Hot Springs, N. C., February 1.

HERMAN TURK, Lima, Ohio, to Miss Daphne Stout in Georgetown, Ky., February 13.

Deaths

John Bion Bogart ⊕ Lower Granville, N. S., Canada; University of the City of New York Medical Department, 1884; an Affiliate Fellow of the American Medical Association; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; consulting surgeon to the Kings County, Jewish, Wyckoff Heights, Methodist Episcopal and Unity hospitals and the Brooklyn Home for Consumptives; aged 79; died, January 18, in the Memorial Hospital, Middleton.

Edwin Milton Beery ⊕ Brooklyn; Bellevue Hospital Medical College, New York, 1897; senior surgeon to the Brooklyn Eye and Ear Hospital; consulting ophthalmologist to the Kingston Avenue Hospital and formerly director of eye service, Brooklyn Jewish Hospital; at one time assistant director of hospitals of New York City Department of Health; aged 67; died, January 30, in St. John's Hospital of heart disease.

Percival James Eaton, Provincetown, Mass.; Harvard University Medical School, Boston, 1888; member of the American Pediatric Society; on the staff of the Columbia Hospital, 1906-1918; past president of the staff of St. Margaret Memorial Hospital and on the staff of the Children's Hospital, Pittsburgh; aged 76; died, Dec. 28, 1938, in the Olean (N. Y.) General Hospital of carcinoma of the colon.

Jacob Treichler Butz ⊕ Allentown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; secretary of the Lehigh County Medical Society and the Lehigh Valley Medical Society; president of the Lehigh County Tuberculosis Society; for many years county medical director; city health officer; formerly county coroner; aged 65; died, Dec. 22, 1938, of cerebral thrombosis.

Ernest Loyd Cartwright, Springfield, Mo.; St. Louis University School of Medicine, 1926; member of the Missouri State Medical Association; on the staff of the Springfield Baptist Hospital, and on the associate staffs of the Burge and St. John's hospitals, aged 37; died, Dec. 30, 1938, in the Missouri Baptist Hospital, St. Louis, of complications following a nephrotomy for kidney stones.

William Cantrell, Greenville, Texas; Arkansas Industrial University Medical Department, Little Rock, 1897; member of the State Medical Association of Texas; past president of the Hunt-Rockwall-Rains Counties Medical Society; formerly member of the state board of medical examiners; physician in charge of a hospital bearing his name; aged 67; died, Dec. 28, 1938, of heart disease.

Robert Henry Ash, Canastota, N. Y.; College of Physicians and Surgeons, Buffalo, 1883; Hahnemann Medical College and Hospital, Chicago, 1884; member of the Medical Society of the State of New York; formerly health officer; on the staffs of the Canastota (N. Y.) Memorial Hospital and the Oneida (N. Y.) Hospital; aged 81; died, Dec. 19, 1938, of coronary thrombosis.

Randolph Faries, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1888; at one time professor of physical education at the University of Pennsylvania; formerly physician-in-chief of the city department of public welfare; aged 76; died, Dec. 30, 1938, in the Graduate Hospital of pneumococcic lobar pneumonia and arteriosclerotic heart disease.

Chester M. Carlaw, Minneapolis; McGill University Faculty of Medicine, Montreal, Que., Canada, 1891; member of the Minnesota State Medical Association; fellow of the American College of Surgeons; surgeon to the Northwestern and Minneapolis General hospitals; aged 68; died, January 7, of coronary sclerosis and diabetes mellitus.

Philip Sheridan Goodwin, Perry, N. Y.; Western Reserve University School of Medicine, Cleveland, 1885; member of the Medical Society of the State of New York; for many years coroner and village health officer; aged 73; died, Dec. 13, 1938, in the Rochester (N. Y.) General Hospital of arteriosclerotic heart disease.

Ward Eugene Collins ⊕ Kalamazoo, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1908; member of the American Academy of Pediatrics; served during the World War; aged 55; on the staff of the Bronson Methodist Hospital, where he died, Dec. 31, 1938, of cerebral hemorrhage.

Vernon Alfred Gotcher, Lancaster, Pa.; University of Arkansas School of Medicine, Little Rock, 1931; member of the Medical Association of Georgia; formerly assistant professor of pathology at the University of Georgia School of Medicine, Augusta; aged 37; died, Dec. 2, 1938, of coronary occlusion.

Elbridge Arthur Carpenter, Passaic, N. J.; University of Vermont College of Medicine, Burlington, 1909; aged 56; died, January 1, in the General Hospital, Paterson, of purulent bronchiectasis and bronchopneumonia, following burns of the face received when he fell asleep while smoking.

Merchant C. Householder ⊕ Pottsville, Pa.; Jefferson Medical College of Philadelphia, 1888; past president of the Schuylkill County Medical Society; on the staff of the Pottsville Hospital; aged 74; died, Dec. 17, 1938, of a dissecting aneurysm of the aorta and arteriosclerosis.

Elmer Ellsworth Bamford, Centerville, Iowa; College of Physicians and Surgeons, Keokuk, 1890; Rush Medical College, Chicago, 1893; fellow of the American College of Surgeons; on the staff of St. Joseph's Hospital; aged 72; died, January 6, in Appanoose of cerebral hemorrhage.

Christopher James Carr, Framingham, Mass.; Medico-Chirurgical College of Philadelphia, 1901; formerly member of the board of health; for several years school physician; aged 63; on the staff of the Framingham Union Hospital, where he died, Dec. 21, 1938, of chronic myocarditis.

John Dean Shipman, Vernon, N. Y.; Syracuse University College of Medicine, 1898; member of the Medical Society of the State of New York; served during the World War; formerly health officer and coroner of Vernon and Geneva; aged 63; died, Dec. 18, 1938, of heart disease.

James Rankin McCarrell, Pittsburgh; Jefferson Medical College of Philadelphia, 1883; member of the Medical Society of the State of Pennsylvania; aged 78; died, Dec. 12, 1938 in the Allegheny General Hospital of a skull fracture received when he was struck by an automobile.

Andrew Stephen Backus, St. Paul; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1905; member of the Minnesota State Medical Association; formerly deputy coroner; aged 57; was found dead, January 20, of carbon monoxide poisoning.

Amos Henry Baldwin, Pleasant Hill, Mo.; Hahnemann Medical College and Hospital, Chicago, 1890; member of the Missouri State Medical Association; past president of the Cass County Medical Society; aged 72; died, January 27, of pernicious anemia.

Richard H. Hutchings Jr., ⊕ Wingdale, N. Y.; Syracuse University College of Medicine, 1919; member of the American Psychiatric Association; on the staff of the Harlem Valley State Hospital; aged 44; died, Dec. 14, 1938, of coronary occlusion.

Emerson Joel Linsday, Walled Lake, Mich.; Detroit College of Medicine and Surgery, 1927; member of the Michigan State Medical Society; formerly member of the health department of Detroit; aged 43; died, Dec. 25, 1938, of coronary occlusion.

Norman Olaf Dalager, Anamoose, N. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; member of the North Dakota State Medical Association; aged 60; died, Dec. 27, 1938, in a hospital at Minot.

James Edgar Doig, Endicott, N. Y.; Albany (N. Y.) Medical College, 1899; member of the Medical Society of the State of New York; county coroner; aged 63; died, Dec. 31, 1938, in the Ideal Hospital, of cerebral hemorrhage and hypertension.

Gustaf Hugo Johnson ⊕ Savannah, Ga.; Long Island College Hospital, Brooklyn, 1898; county coroner; served during the World War; on the staff of the Warren A. Candler Hospital; aged 67; died, Dec. 28, 1938, of acute dilatation of the heart.

Leroy Cholula Goff, Clarksburg, W. Va.; University College of Medicine, Richmond, 1906; member of the West Virginia State Medical Association; formerly county coroner; on the staff of St. Mary's Hospital; aged 60; died, Dec. 22, 1938.

William Brown Thistle, Toronto, Ont., Canada; Victoria University Medical Department, Coburg, Ont., 1886; L.R.C.P., London, 1887; formerly associate professor of clinical medicine, University of Toronto Faculty of Medicine; died, Dec. 17, 1938.

Charles Lincoln Bliss, Washington, D. C.; University of the City of New York Medical Department, 1891; member of the Medical Society of the District of Columbia; formerly a medical missionary; aged 73; died, January 21, of cerebral thrombosis.

John Thomas Davis, Liberty, Kan.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1879; member of the Kansas Medical Society; formerly county health officer; aged 85; died, Dec. 26, 1938, of chronic myocarditis.

Richard August Morgner, Fitchburg, Mass.; Tufts College Medical School, Boston, 1902; member of the Massachusetts Medical Society; for many years on the staff of the Burbank Hospital; aged 65; died, Dec. 27, 1938, of diabetes mellitus.

Henry Herbert, Los Angeles; Medizinische Fakultät der Universität Wien, Austria, 1891; at one time associate professor of physical diagnosis at the College of Physicians and Surgeons, Los Angeles; aged 72; died, Dec. 15, 1938, of heart disease.

Charles Le Baron ⊕ Gulfport, Miss.; Medical College of Alabama, Mobile, 1889; past president of the Harrison County Medical Society; on the staff of the King's Daughters' Hospital; aged 70; died, Dec. 11, 1938, of chronic nephritis.

Joseph Thomas Brennan ⊕ Grandview, Mo.; St. Louis University School of Medicine, 1908; county health officer; served during the World War; aged 56; died, Dec. 31, 1938, in St. Joseph Hospital, Kansas City, of coronary thrombosis.

Peter M. Campbell, Elgin, Ill.; Detroit College of Medicine, 1891; member of the Illinois State Medical Society; on the staffs of St. Joseph's and Sherman hospitals; aged 78; died, January 17, of lobar pneumonia and chronic myocarditis.

James Percy Powell, Mangham, La.; Arkansas Industrial University Medical Department, Little Rock, 1896; aged 70; died, Dec. 5, 1938, in Vicksburg (Miss.) Sanitarium, of arteriosclerotic heart disease and chronic nephritis.

Frederick Durand Davis ⊕ Springfield, Mass.; University of Vermont College of Medicine, Burlington, 1910; served during the World War; on the staff of the Mercy Hospital; aged 54; died, Dec. 31, 1938, of coronary thrombosis.

Charles Henry Root ⊕ Bassett, Neb.; University of Nebraska College of Medicine, Omaha, 1903; aged 62; died, Dec. 14, 1938, in the Methodist Hospital, Omaha, of retroperitoneal abscess and chronic cholecystitis.

Aaron Thomas Colley, Enterprise, Ala.; University of Louisville (Ky.) Medical Department, 1894; member of the Medical Association of the State of Alabama; aged 69; died in December 1938 of coronary thrombosis.

Joseph Henry Boyles, Greensboro, N. C.; College of Physicians and Surgeons, Baltimore, 1903; veteran of the Spanish-American War; on the staff of the Piedmont Hospital; aged 65; died, January 24, of lymphosarcoma.

Albert Smith Parker, Clinton, Wis.; Northwestern University Medical School, Chicago, 1901; member of the State Medical Society of Wisconsin; aged 69; died, Dec. 10, 1938, in Sawtelle, Calif., of arteriosclerosis.

Alexander Rudolph Chillag ⊕ Buffalo; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultasa, Budapest, Hungary, 1918; aged 45; died, Dec. 20, 1938, of arteriolar nephrosclerosis and hypertension.

George Wesley Blanchard, Pelham, N. Y.; Medical School of Maine, Portland, 1895; consulting physician to the United States Military Academy at West Point; aged 70; died, January 17, of coronary thrombosis.

Omer Rocelus Alexander, Winter Haven, Fla.; Atlanta Medical College, 1893; member of the Florida Medical Association; aged 66; died, January 25, in Dunedin of coronary occlusion and thrombosis.

Ole Hansen Berg, Chicago; College of Physicians and Surgeons of Chicago, 1896; on the honorary staff of the Norwegian-American Hospital; aged 71; died, January 8, of diabetes mellitus and hypertension.

Arthur Wesley Thomas, Salem, N. Y.; Albany (N. Y.) Medical College, 1904; for many years health officer of Jamaica, Vt., and school director; aged 61; died, Dec. 17, 1938, in Brattleboro, Vt., of myocarditis.

David A. Hewit, Spokane, Wash.; John A. Creighton Medical College, Omaha, 1904; member of the Washington State Medical Association; aged 57; died, Dec. 27, 1938, at Santa Ana, Calif., of arteriosclerosis.

Wilson Canfield, Eaton Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; aged 79; died, January 8, of arteriosclerosis, diabetes mellitus and chronic myocarditis.

Thomas Willett Bishop ⊕ South Pasadena, Calif.; Bellevue Hospital Medical College, New York, 1895; medical director and owner of the Pasadena Sanitarium; aged 68; died, Dec. 28, 1938, of cerebral hemorrhage.

Chester C. Impey, Omaha; John A. Creighton Medical College, Omaha, 1903; on the staffs of the Lutheran and St. Catherine's hospitals; aged 58; died, Dec. 11, 1938, in Oakland, Calif., of heart disease.

Charles Pelton Hutchins ⊕ Syracuse, N. Y.; Long Island College Hospital, Brooklyn, 1897; served during the World War; aged 66; died, Dec. 28, 1938, of coronary thrombosis and cerebral embolism.

John Lockwood Baker ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1905; for many years member of the city health department; aged 61; died, January 4, in the Swedish Hospital of pneumonia.

Julius A. Fowler, Malakoff, Texas; Louisville (Ky.) Medical College, 1892; formerly county health officer and member of the state board of medical examiners; aged 69; died, Dec. 5, 1938, of bronchiectasis.

Albert F. Merrell, Hallstead, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1888; member of the state legislature; bank president; aged 72; died, Dec. 2, 1938, of carcinoma of the prostate.

Alexander Lane Brobeck, Hoopeston, Ill.; University of Louisville (Ky.) Medical Department, 1885; member of the Illinois State Medical Society; aged 85; died, January 16, of cirrhosis of the liver.

Henry Delapierre White, Lancaster, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887; aged 72; died, Dec. 2, 1938, of coronary thrombosis.

Mark Duane Gundrum ⊕ Westville, Ill.; Loyola University School of Medicine, Chicago, 1916; served during the World War; aged 49; was found dead, Dec. 25, 1938, of coronary thrombosis.

Willis E. Stewart ⊕ Stratton, Neb.; Central Medical College of St. Joseph, Mo., 1900; medical director and owner of a hospital bearing his name; aged 63; died, Dec. 30, 1938, of chronic myocarditis.

Harvey William Marvin, Washington, D. C.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1897; aged 64; died, Dec. 17, 1938, of cerebral hemorrhage and chronic myocarditis.

Albert Mason Tyler, Long Beach, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1886; aged 80; died, Dec. 11, 1938, of diabetes mellitus and cerebral thrombosis.

John Sheridan Arnold ⊕ Washington, D. C.; College of Physicians and Surgeons, Baltimore, 1896; for many years school medical inspector; aged 73; died, January 6, of cerebral hemorrhage.

William Allan Taltavall ⊕ Redlands, Calif.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885; aged 79; died, Dec. 22, 1938, of coronary disease.

Richard Alexander Peters, Tipton, Iowa; Rush Medical College, Chicago, 1884; aged 75; died, Dec. 11, 1938, in Chicago of hypernephroma of the left kidney with metastasis to the pubic bone and pelvis.

Arthur Morris Cohen ⊕ Philadelphia; University of Pittsburgh School of Medicine, 1925; aged 38; died Dec. 26, 1938, in the Mount Sinai Hospital, Cleveland, of coronary arteriosclerosis and thrombosis.

Walter B. Weaver, Cincinnati; Medical College of Ohio, Cincinnati, 1890; member of the Ohio State Medical Association; formerly county coroner; aged 70; died, Dec. 14, 1938, of arteriosclerosis.

Joseph Roop Smith, Marydel, Md.; University of Pennsylvania Department of Medicine, Philadelphia, 1887; aged 72; died, Dec. 24, 1938, in the Kent General Hospital, Dover, Del., of pneumonia.

Charles L. Ackerman, Brownstown, Ind.; Kentucky University Medical Department, Louisville, 1903; member of the Indiana State Medical Association; aged 71; died, January 4, of pneumonia.

Monroe F. Clouser ⊕ Oley, Pa.; Medico-Chirurgical College of Philadelphia, 1907; aged 55; died, Dec. 6, 1938, in St. Joseph's Hospital, Reading, of coronary occlusion and diabetes mellitus.

John Henry Rumpf, Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1896; aged 76; died, Dec. 1, 1938, of heart disease.

John Clyde MacDonald, Edmonton, Alta., Canada; Halifax (N. S.) Medical College, 1895; aged 70; died, Dec. 28, 1938.

Ezra A. Haist, Ottawa, Ont., Canada; University of Toronto Faculty of Medicine, 1895; died, Dec. 12, 1938.

Correspondence

ANATOMY OF SPHINCTER

To the Editor:—In The Journal February 18 an article by Blaisdell refers to my work on the anatomy of the anal sphincter and the etiology of fistula. After reading Dr. Blaisdell's article several times I feel that both he and the discusser, Dr. Hill, have overlooked several important points in my work and that they have failed to correlate certain age-old clinical observations with actual anatomic manifestations. Some of these observations are that:

1. There is a definite relation between the internal and external orifices of a fistula. A fistula having its external orifice situated behind a plane passing transversely through the center of the anus usually has its internal aperture in the posterior commissure of the anus at points corresponding to 5 or 7 on the clock, the posterior median line being considered as 6 o'clock.

2. A subcutaneous fistula has its external opening within 1 inch of the anus and the internal opening external to Hilton's white line.

3. In submuscular fistulas the internal opening is usually between the sphincters.

The explanation of these observations is contained in my article on this subject published in *Surgery, Gynecology and Obstetrics* in May 1931. It demonstrates that the course of fistulous tracts does not follow the intermuscular septum but, in those cases in which the fistula passes into the ischiorectal fossa, the internal opening corresponds to the points at which the vessels traversing the ischiorectal fossa enter the submucous region of the anus, namely 5 and 7 o'clock posteriorly.

The external longitudinal coat of the large intestine is at best a rather weak structure. Some of the fibro-elastic terminations of this coat of the bowel pass through the internal sphincter to the submucous region caudad to the muscularis mucosae; others pass between the layers of the external anal sphincter muscle to insert into the cornified skin around the anus, and still others insert into the levator ani muscles. These observations are clearly portrayed in my article on Hilton's white line in the *Annals of Surgery* of July 1935. Dr. Blaisdell has apparently made the same mistake as many other workers in this field who have considered the anatomy from the observations made on surgical specimens and autopsy material instead of the living patient. An accurate picture of the relationship of the various muscles cannot be obtained after death because the muscles are relaxed and do not maintain their normal positions. Hilton emphasized this fact when he referred to his white line as being present "in the living." When the sphincters are contracted the external sphincter is caudad to the internal sphincter, which is the thickened termination of the inner circular coat of the rectum. The strongest coat of the intestine, as every surgeon knows, is the submucous coat. This is the coat which is used in the making of catgut. It is also the coat through which the surgeon likes to have his intestinal suture pass in order to secure firm union. This fact was emphasized by Halsted and Gross. Microscopic study of the anal region discloses that the thick fibrous area described by Milligan and Morgan and quoted by Blaisdell as the intermuscular septum is really a much thickened submucous layer.

Although the anatomy of the external sphincter muscle of the anus does follow a certain general pattern, it varies so greatly in individual specimens, as disclosed by my studies, that it cannot account for the more or less constant location of the internal opening of the fistula.

The points raised by Blaisdell on the subjects of cutting the muscles during operations on a fistula, the dangers of dilating the rectum, the physiology of the sphincter muscles and the observations made on palpation of the anus are all discussed in my articles already cited.

Robert I. Hiller, M.D., Milwaukee.

COINS COMMEMORATING PHYSICIANS

To the Editor:—In The Journal, Aug. 27, 1938, page 863, Dr. E. F. Kiser stated that he knew of no coin bearing the portrait of a physician other than the one struck by Austria in 1929 commemorating Theodor Billroth.

Lithuania in 1936 commemorated Dr. Jonas Basanavicius on a 5 litas silver coin, and Brazil in 1937 struck a 400 reis nickel coin with the portrait of Oswaldo Cruz.

I should be glad to hear from interested physicians if other such coins have been issued by any country.

L. Grant Glickman, M.D., Minneapolis.

A SIMPLE METHOD OF PLASMA TRANSFUSION

To the Editor:—The intravenous administration of blood plasma is recognized as a rational procedure in the therapy of secondary shock resulting from loss of blood plasma and consequent increase in concentration of the blood, as in crushing injuries and burns. Although whole blood transfusions are of therapeutic value in these conditions, the red cells serve no useful purpose and tend to prevent the rapid correction of increased blood viscosity. It can be said, with possibly some reservation, that plasma transfusion also appears to be logical in hypoproteinemia resulting from the combination of starvation and parenteral administration of crystalloid solutions in the treatment of acute abdominal disease.

"Lyophile" serum (Flosdorf and Mudd, *J. Immunol.* 29:389 [Nov.] 1935) has been developed for use in these conditions and has received clinical trial. Unfortunately the preservation of human blood serum in dry form is complex and costly and its development has not yet been carried to a point at which it can be used without the fear of reactions or contamination.

This brief communication is to point out that human plasma is available safely, immediately and cheaply to any one who has access to a blood bank. Stored blood, standing at rest in the refrigerator, separates into plasma and cell layers. During the past six months in the Department of Surgery and Gynecology of the University of Virginia Hospital we have employed the supernatant plasma in cases of shock presenting increased blood concentration and in cases of hypoproteinemia from starvation. In the former group of cases the results have been satisfactory. In the latter group a larger series of cases than ours will be needed before the results can be appraised. The principle is presented therefore only as a suggestion for a method of treatment, obviously safe and theoretically logical.

Whole citrated blood transfusions are given at the University of Virginia Hospital by the closed method, a single flask for collecting, storing and delivering the blood being used. The supernatant plasma can be obtained by aspiration. A sterile glass tube attached to the negative pressure collection apparatus which is used in obtaining blood from donors is carefully inserted in the storage flask and the plasma layer is sucked over into a flask, which is then used to deliver the plasma to the recipient.

The underlying precautions as to typing, cross matching, serologic study and storage period of the blood to be used for plasma transfusion are observed just as though the whole blood were to be employed. The matching must be perfect in both directions—i. e., donor's plasma vs. recipient's cells and recipient's plasma vs. donor's cells—and must be carried out just before use of the plasma. The plasma should be administered immediately after collection in order to avoid bacterial growth from minor degrees of possible contamination from the air. With the precautions used it is obvious that the spilling over of a small portion of the cell layer will not create danger. Nor will it defeat the major purpose of the procedure.

The red cell layer remaining in the donor flask may also serve a useful end. In a number of instances, after proper additional

matching, the erythrocytes suspended in salt solution have been given to patients with anemia. The value of this procedure is as yet undetermined, but it would seem to be logical in cases of hemolytic sepsis in which the essential problem in repeated transfusions is the replacement of red cells and not of plasma.

It is presumed that these simple procedures have occurred to many others dealing with bank blood In the rapidly growing literature on the blood bank, reference to them has not been encountered.

University of Virginia Hospital.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST

POLIOMYELITIS VIRUS

To the Editor —Kindly advise me regarding the following with reference to poliomyelitis 1. How is the presence of a virus in nasal washings or in stools determined? Has any other method than injection of monkeys been devised? 2. It is stated that there are numerous types of the virus (of poliomyelitis) with different characteristics How has this been determined? 3 How is it possible to determine whether or not antibodies exist in serum?

M D, Alabama

ANSWER—1. The virus of poliomyelitis is detected in nasal washings or stools by processing the material submitted for the test Such material is then tested for infectivity by intracranial inoculation in susceptible monkeys. The technic used in preparing this material is that of suspension in a suitable aqueous menstruum with filtration through a bacteria-tight filter, followed by concentration of the fluid medium to a small volume by distillation in vacuo. There is no test for the presence of poliomyelitis virus other than the inoculation test in monkeys

2 The viruses of poliomyelitis can be defined by two means: (*a*) immunologic properties and (*b*) variable effect following inoculation into monkeys. The immunologic methods that have been used to define the poliomyelitis virus are the insusceptibility of animals to cross inoculation and cross protection tests The differences in individual properties of the virus include a different mortality rate and extent of paralysis as produced in experimental animals.

3 The means of determining the presence of antibodies in serum are the following Each serum is tested by mixture with a standard infectious dose of virus and incubated in vitro at 37 C The mixture is then tested for infectivity in monkeys. If the mixture produces the disease in animals, the serum is said to contain no protective antibodies. These tests may also be carried out on a quantitative basis.

FROHLICH SYNDROME

To the Editor —A boy aged 15 presents a typical picture of Fröhlich's syndrome Reports regarding the value of pituitary substance in these cases vary widely. What is the best accepted treatment? The patient's chief complaint is perspiring, especially on the hands. Physical examination is entirely negative except for blood pressure of 148 systolic 88 diastolic What would cause perspiration, granted that it is not due to a nervous cause? How can I reconcile it with pituitary disturbance?

J J ZONE, M D, Wayland, N Y.

ANSWER—Opinions vary regarding "the typical picture of Frohlich's syndrome" This description is often applied to boys who are simply too fat and whose sexual development is somewhat delayed Many of these boys "straighten around" with a little patience and a weight reduction regimen Williams studied a large group of boys of this type who were admitted to an English school and found that 87 per cent of them became normal spontaneously. This does not mean that the boy described does not have Frohlich's syndrome; it simply suggests the need for caution in making this diagnosis It should be added that this "typical syndrome" is found also in many boys who are mentally deficient Hecker and Warren report many such examples.

Assuming that this patient has Frohlich's syndrome, there are at least three hormones which may be tried:

1. Pituitary gonadotropic hormone. This hormone, obtained directly from the pituitary, has not been tried in enough cases to warrant any conclusion.

2. Pituitary-like gonadotropic hormones. These have been used more extensively. They are obtained from sources other than the pituitary—usually from the urine of pregnant women or the serum of pregnant mares. They resemble the true pituitary gonadotropic hormone in most ways but probably originate in the chorionic villi and not in the pituitary. The horse serum has not been utilized sufficiently to draw conclusions and has the usual disadvantages associated with the use of any horse serum. The hormone from the urine of pregnant women has been used must frequently but not always in well selected cases and the results are not always evaluated in a critical fashion. In the case mentioned this hormone might be tried. The dosage has varied, but 500 or 1,000 units two or three times a week for ten to twelve weeks should constitute an adequate trial period A note of caution is not out of order. Thompson and Heckel reported several cases of marked enlargement of the genitalia from the use of this hormone.

3 Testosterone propionate. This may be the method of choice. Testosterone propionate is the male hormone in its crystalline form. A recent article by Kenyon has reviewed this subject and reports some interesting cases. If this hormone is to have any effect in the case described it should manifest itself after a period of from ten to twelve weeks' treatment, the patient being given 25 mg. of testosterone propionate hypodermically each week

The inquirer does not mention the patient's basal metabolic rate If this is low, he may need thyroid extract. In any event he should follow a weight reduction regimen although both of these suggestions may affect the interpretation of improvement if endocrine substances are used. The single blood pressure reading may not be significant; it should be checked every hour for twenty-four hours It probably is not related to the Frohlich syndrome The sweating is of questionable significance and may disappear with improvement in the patient's general condition.

COLD ABSCESSES OF OLD AMPUTATION STUMP

To the Editor.—A World War veteran aged 47 suffered multiple wounds of his right leg and thigh and underwent a mid thigh amputation in 1918. As the result of infection, healing was delayed for more than a year. Since 1920, however, he has worn a prothesis without trouble, except for the removal of two small bits of shrapnel in 1930 Since early in 1937 two small localized, discrete masses about the size of chestnuts have appeared subcutaneously on the anteromedial aspect of the thigh 2 inches below the inguinal ligament just distal to the rim of the prothesis The masses disappear spontaneously as a rule after two or three weeks and then recur in four or six weeks They are quite tender In September 1938 one mass developed into a small "cold" abscess, which was aspirated for examination, then incised It promptly healed, and the other mass disappeared Both recurred a month later and disappeared after incision of the abscess Today, Nov. 21, 1938, I find both have recurred for the third time The man's general health is excellent The bacteriologic examination revealed "an acid fast bacillus resembling the tubercle bacillus" The patient had a negative Mantoux test in a dilution of 1 500 of old tuberculin He has no lymphatic enlargement, his red count, white count and differential counts are normal, and his Wassermann reaction is negative X ray examination of the stump reveals no disease of the bone nor any shadows of shrapnel. Could this be caused merely by irritation of the artificial limb, although it apparently fits perfectly? Could smegma bacilli gain entry through apparently healthy skin and cause such a condition? Is this condition common among men wearing artificial limbs? Any suggestions you may offer as to cause and treatment will be greatly appreciated.

JOSEPH C. ANDERSON, M D, Ebensburg, Pa.

ANSWER.—It is probable that in this case the irritation of the artificial limb plays but small if any part It would seem that this is most likely a tuberculosis of the skin. An attempt should be made to confirm this by further stained slides at the time of the next abscess. Possibly a guinea pig injection would be of use. General measures to improve the man's health, as in tuberculosis elsewhere, should be of value, and when there is any suspicion that one of the abscesses is forming the artificial limb should not be worn.

BODY ODOR

To the Editor:—A patient, white, single and 21, has never been ill. The family history is negative. The menstrual history is normal. Beginning about two years ago this girl noticed a peculiar odor like coffee about her person. This lasted for about an hour or so and then disappeared. Her friends notice it also. The odor does not come from her mouth and appears at irregular times with no apparent relationship to meals or menses. It may occur while she is working or while she is out with friends and it has become most embarrassing. Physical examination, including examination of the urine, is completely negative. The diet has not influenced the condition. Could you possibly suggest a cause and line of treatment?

M.D., New York.

ANSWER.—The study of body odors aroused considerable interest among the dermatologists of former days but nothing has been found in the medical literature of the last several years. The public is now particularly alert in this respect as the result of the insistent advertising of commercial products designed to correct or overcome such odors.

Odors may originate from (1) gas escaping from the bowel without the knowledge of the person, (2) bad breath, (3) discharge from the ears, (4) vaginal discharge, (5) decomposing sweat, sebum or urine on the skin or clothing, or (6) the peculiar odor of freshly secreted sweat. The query seems to rule out all except the last cause. Certain foods and drugs are credited with producing sweat of a peculiar odor. Alcohol, coffee, various ethers, garlic, valerian, asafetida and other gum resins, angelica, truffles, musk, turpentine, tar, sulfur, benzoic acid, iodine, iodides, phosphorus, zinc phosphate and copaiba are listed as having this power.

Nervous influence is also credited with the production or alteration of the body odor. There are many reports dealing with neurotic or hysterical individuals who emanate peculiar odors, pleasant or the opposite, during attacks. Fraud must always be suspected. In the case under consideration, an effort should be made to check the claims of the patient and her friends. She should be examined for a possible parosmia due to organic or functional nervous disease.

If it can be determined that the odor is in the sweat, the axillae may be dabbed frequently with from 1 to 5 per cent solution of salicylic acid in alcohol or from 1 to 5 parts of "solution of formaldehyde-U. S. P." and alcohol to make 100 parts. Potassium permanganate 1:3,000 in water may be applied as a wet compress or 1 per cent solution of the same drug may be painted on once a day. Applications about the genitalia must be made with more care. If there is any hyperhidrosis, x-rays filtered through 1 mm. of aluminum, 70 roentgens once a week may be given until the abnormal sweating is checked. If this is not possible, 25 per cent aluminum chloride in distilled water may be dabbed on once every third day and allowed to dry on. No soap should be used immediately before its application, and it must be allowed to dry completely before the clothing is put on. This is too apt to irritate to allow its use in the anogenital region.

The patient must be told repeatedly that others do not notice the odor as she does and that she must not allow herself to indulge in worry over it, for an olfactory neurosis is most difficult to overcome.

STUTTERING

To the Editor:—In May 1938 a woman aged 25, unmarried, a school teacher, was taking 1 grain (0.065 Gm.) of plasmochin daily. After two or three days she developed circumoral and ocular bluish discoloration, abdominal pain, shortness of breath, stuttering and hoarseness, anorexia and constipation. After about two months of tonics (iron, quinine and strychnine) she recovered in all respects except the stuttering. This has remained and becomes worse when she is tired. I will appreciate any comments both as to further treatment and as to the prognosis. Treatment so far has been nothing more than tonics, fresh air and exercise.

WATSON WHARTON, M.D., Smithfield, N. C.

ANSWER.—The patient should begin by taking some short verse and sounding a note over each word, starting the word with a low note and reaching the middle of the word with the octave and then coming down to the low note again on the remainder of the word. This should be practiced for three periods a day, each period being fifteen minutes long and one of the periods occurring before she retires for the night. After the patient can do this note with ease it can then be applied in her conversation over any word in which speech difficulty arises. The idea is to build for the time being a melody control over the speech, since it is impossible to stutter in the melody area. After two or three weeks of practice she may then pick out another short verse and use the note over the whole line instead of each word. To illustrate: In the line "This is the forest primeval" she should start the low note on *thi* of the word *this* and reach the octave on the *i*, drawn out and the *s*, coming down slowly on the rest of the sentence. This second note is then applied in the conversation after it has become easy in place of the first note. Then in the third step another verse is chosen and the note is so applied that the octave is reached in the middle of the sentence. For example, in the line quoted the octave would be reached in the syllable *for* of the word *forest*. The fourth step is to choose a verse which has pictures easy to visualize and learn it and picture the object for which the word stands as that word is uttered. After considerable practice the patient may then make up stories of ten lines or so of something she has seen and can picture easily. When skill has been developed in doing this, the mental picture of the word can be applied in conversation and the note discarded. Fresh air, exercise and rest are all helpful. At the stated age, with careful and faithful practice it would probably take about six months for recovery, perhaps much less, depending on the severity of the disturbance.

LOSS OF SPONTANEOUS MICTURITION AFTER HYSTERECTOMY

To the Editor:—A woman aged 26 was submitted to a subtotal hysterectomy for relief of menorrhagia. Immediately after the operation she voided urine twice. Ten weeks has now elapsed and catheterization has been necessary all the time. Distention of the bladder causes no distress and she cannot void voluntarily. There was nothing out of the ordinary about the operation and no perineal work. The Kahn reaction was negative and urologic examination gave negative results. How common is such an occurrence and what is the recommended treatment?

F. E. BOLLAERT, M.D., East Moline, Ill.

ANSWER.—Difficulty with reestablishment of spontaneous urination occurs most frequently in those cases in which there has been considerable mobilization or denudation of the bladder, with impairment of the nerve supply. In this case the question arises as to whether the bladder was stripped downward from the uterus for a considerable distance. If the patient is otherwise normal, a return of the power of spontaneous micturition is to be awaited with confidence.

A helpful procedure is daily distention of the bladder with sterile water, a rubber catheter and a 50 cc. or larger syringe. The bladder is filled until the patient complains of discomfort; then it is emptied through the catheter. On succeeding days the procedure is repeated, always with avoidance of producing excruciating pain, yet with the intent of ironing out folds and creases sufficiently to induce the return of function. "Distention treatment" has yielded gratifying results in nearly all cases in which there has been a persistent loss of bladder tone.

Except in patients with organic nerve lesions, persistent lack of tone is of extreme rarity, seemingly limited to patients with marked myasthenic symptoms.

TREATMENT FOR DRY SCALP—VITALIS

To the Editor:—What medication would you suggest for a dry scalp? Is "Vitalis" injurious to the scalp or beneficial? Is castor oil or olive oil satisfactory?

M.D., Washington, D. C.

ANSWER.—In all probability the underlying factor producing a dry scalp is seborrhea, of which there are two types. In one variety there is excess oil and this is accordingly termed "oily seborrhea." The other type of seborrhea is the dry type, or "seborrhea sicca." The principal characteristic of this is a dry scaling scalp. The scales themselves may be oily. The hair and scalp are lusterless and the latter is of a grayish hue. There may be moderate itching. In the treatment of all types of seborrhea, sulfur stands first. Among other useful agents are resorcinol, salicylic acid and mercurials such as the ammoniated and the bichloride. It is best to begin with pomades and after improvement of the scalp continue with lotions, which are more elegant and are more appreciated by the patient. The treatment should be continued for a relatively long time, because seborrhea is essentially a chronic disorder. Castor oil and olive oil may be used on the scalp but preferably in combination with some of the agents mentioned. Olive oil may be useful as a shampoo in certain types of seborrhea.

The Bureau of Investigation of the American Medical Association reports that it does not know what "Vitalis" contains. It has received reports from at least two physicians that irritation followed the use of "Vitalis." In June 1937 the Federal Trade Commission at Washington reported that it had obtained a promise from the Bristol-Myers Company to stop representing that its hair tonic, Vitalis, retards falling hair, unless limited to indicate excessive falling hair; that the product, combined with a massage treatment, brings new life and looks to the hair by giving it a chance to grow at the roots and scalp, and that it contains oils that hair requires for health.

GABRIEL'S SOLUTION FOR PRURITUS ANI

To the Editor:—Can you furnish me with information as to the composition of Gabriel's solution, used in the treatment of pruritus ani by injection, its method of use and the rationale?

MARION W. HESTER, M.D., Americus, Ga.

ANSWER.—Gabriel uses two solutions in the treatment of anal pruritus: (1) a 3 per cent solution of ethyl aminobenzoate (anesthesin) with benzyl alcohol (5 per cent) and ether (10 per cent) in sterilized olive oil, and (2) a solution composed of nupercaine (0.5 per cent), benzyl alcohol (10 per cent) and phenol (1 per cent) in sterilized oil of sweet almond. He prefers to give a few large injections rather than a series of small ones. He states that a large initial dose of 10 cc., which is injected about the posterior half of the perianal region, is the most significant feature of the treatment. No injection should be given in the presence of acute, moist dermatitis. A 10 cc. syringe is filled with one of the solutions and a needle 3 cm. in length is attached. The perianal skin is prepared in order to produce as nearly as possible a condition of asepsis. The injection is given through four punctures posterior to the anus. In this region is located the principal sensory distribution to the anus (the inferior hemorrhoidal nerve and the perineal branch of the fourth sacral nerve).

At each puncture 2.5 cc. of the solution is injected in a fan-like manner, and the needle should be inserted deeply so that no surface swelling is noticeable at the conclusion of the injection. Abrasions and excoriations about the anal margins should receive local treatment with medicated solutions, ointments and dusting powders.

A second injection of 10 cc. is given from five to seven days after the first. At the time 5 cc. of the solution is distributed by two punctures in relation to the right anterior quadrant and 5 cc. in relation to the left anterior quadrant.

A third injection of 10 cc. is given a week later. These injections are made "on each side of, and posterior to, the anus. The needle is passed forward in the subcutaneous tissues parallel to the surface, 5 cc. being injected on each side."

Thus a total of 30 cc. of the oily anesthetic solution is given. He warns that careful aseptic technic should be used and says that the best results can be obtained if the patient rests in bed for two or three weeks during the time the treatment is being given. Usually in twenty-four hours after each injection the patient notices a feeling of numbness which lasts for from three to six weeks, and during this time Gabriel emphasizes the importance of local treatment. He says that the solution of nupercaine and oil produces more pronounced anesthesia but believes that it does not last any longer than that produced by ethyl aminobenzoate. He has not found that abscesses have occurred in any of his private or hospital patients and has calculated that for about two thirds of his patients the results have been good. Gabriel: The Principles and Practice of Rectal Surgery, London: H. K. Lewis & Co., Ltd., 1937.

MULTIPLE FETUSES AND PLACENTA

To the Editor:—Are there any data with regard to twin births in which there are one and also two placentas? Do children attached to a common placenta and formed by what appears to be bifurcation ever differ in sex? When each child (fetus) is possessor of its own placenta of course one will admit that there were two ova fertilized at one time, but when there is but a single placenta one suspects that only one ovum was impregnated and that it bifurcated and formed two fetuses. Is it a fact that the mother of the Dionne quintuplets at their birth was delivered of only three placentas and that two of those were bifurcated, indicating that only three ova were involved in the generation? My experience in delivering twin births with the fetuses attached to a common placenta is that they are universally of the same sex, which goes to show that the sex of the fetus is determined before or immediately after growth begins from fertilization of the spermatazoon.

T. H. STANDLEE, M.D., Mirando City, Texas.

ANSWER.—Twins who have had a single placental attachment may or may not be of the same sex. Such a placenta may be the result of a fusion of two separate placentas. It is almost impossible, and according to several authors absolutely impossible, to determine by an examination of the placenta whether twins are the result of a single ovum or of separate ova. Detailed microscopic examination may be of some value, but gross examination is of no value. About 5 per cent of monozygotic or single ovum twins have distinct amnions and chorions. Twins arising from the same ovum are always of the same sex. Those arising from separate ova may or may not be. Sex is determined immediately on fertilization of the ovum and is dependent on the spermatozoon.

The famous quintuplets are monozygotic, all having originated from a single ovum. This fact has been definitely determined by a careful study of their finger-print patterns and other characters. At the present time this method of study is the only reliable way of determining whether multiple births arise from a single ovum. Dr. Dafoe had little opportunity to study the placenta of the quintuplets before it was destroyed, but it was his impression that it consisted of a single large placenta.

LIME DEPOSITS FROM WATER AND WATER SOFTENING

To the Editor:—Our water supply has a high mineral content, particularly calcium, which deposits around the cooling system of the engines used to generate electricity, causing excessive heating. To counteract this a thick liquid called "Sandbaum" made by the Sandbaum Company of Fort Worth, Texas has been used. It is called a vegetable colloid and claim is made that it removes lime deposits without chemical action. It costs $15 for 8 ounces, which lasts about one month. Do you have any information on this product? It seems to me that there are chemical water softeners which would be much cheaper than this. Do ordinary water softeners prevent the deposit of lime on instruments and cooking utensils?

L. W. FORNEY, M.D., Mason City, Neb.

ANSWER.—Without knowing the exact chemical characteristics of the water used it is not possible to advise relative to the economics of water treatment and softening for the plant. Waters having calcium bicarbonates in solution will, of course, precipitate the calcium carbonate when the carbon dioxide, which serves to hold the carbonate in solution, is driven off with heating. As a rule where the quantity of water used for condensers is large and the dissolved solids high, water softening by chemical treatment or by passing the water over zeolites is more economical and satisfactory than batch treatment by various chemicals of a colloidal nature. It would probably be prudent and good economy to consult a qualified industrial chemist with regard to this problem.

NODULAR FIBROSITIS

To the Editor:—I should like information on the nature of the small nodular masses frequently palpable over the sacro-iliac synchondroses. They are smooth, rounded, variable in size, firm in consistency, overlying the joint. I find them more often in women, and they appear to be present in cases of both infected and apparently not infected joints. Although they feel like enlarged lymph nodes, I am inclined to think that they are cartilaginous bodies. Have they any significance?

V. E. POWELL, M.D., Atlanta, Ga.

ANSWER.—Small nodular masses, frequently palpable over the sacro-iliac synchondroses, are most often present in patients who have a general ligamentous relaxation not only in that region but throughout the body. This condition is often present around the time of the menopause, when the metabolic processes are at a low ebb and the patient presents a picture of extreme fatigue with lumbar lordosis and poor posture in general. The masses are similar to, if not identical with what has been called nodular fibrositis, which also may be present about the shoulder region and in the muscles or ligaments of the upper dorsal spine between the blades of the scapulae.

They have been examined microscopically, following excision, and consist of extremely edematous, fibrous, connective tissue. The cause is thought to be a low grade chronic inflammation, probably not on an infectious basis. They are present in many instances when chronic strain or stretching of the superficial ligaments exists. It is probable that any type of chronic irritation in the presence of poor muscle tone and poor venous circulatory return predisposes to the development of these nodules. Such nodules may be expected to disappear when the posture is improved and the muscle tone, strength and circulation are restored to normal.

SCARLET FEVER IMMUNIZATION

To the Editor:—What is the present status of scarlet fever immunization? Should one recommend that all children be given the five doses of scarlet fever toxin? I have not felt that there has been enough evidence to warrant the universal use of the scarlet fever toxin.

M.D., Illinois.

ANSWER.—Inoculation of toxin according to the Dick method for the prevention of scarlet fever is not universally accepted without question. Pediatricians as a rule do not recommend the routine use of this procedure. Only those subjects shown to be susceptible on the basis of a positive Dick reaction should be injected with Dick toxin for the purpose of immunization. Usually a susceptible person who has received the five regular doses of Dick toxin does not develop clinical scarlet fever if exposed to the disease. However, immunization against streptococcic infections is not established. The Dick plan for scarlet fever immunization is carried out in many hospitals and other institutions, where it is of undoubted value.

PRURITUS FROM WATER

To the Editor:—A married woman aged 28 complains of an annoying pruritus, i. e., a generalized itching on her body only after taking a bath. If she washes clothes or dishes she has itching only where the water touches her. When water splashes on her chest when she is bathing her baby the spot where the water touches her body itches. This pruritus occurs regardless of whether she uses soap or not or whether the water is cold or hot. She is fastidious, taking baths at least once daily, often twice daily. Restricting the use of water, i. e., bathing herself, gives her comparative freedom from itching in between bathing. The use of soothing ointments after bathing does not lessen the itching. She is a moderate hyperthyroid, having a basal metabolic rate of + 29, but under medical care her pulse has come down from 115 to 92 and her nervousness has improved greatly. She has no palpable thyroid and no exophthalmos. The urine, Wassermann reaction and blood counts are all negative. What can be done for this woman? Is it possible to desensitize her? Can a cause be found for this itching? Is there anything that can be given to allay her itching after bathing?

THOMAS MESSINA, M.D., Newark, N. J.

ANSWER.—The cause of ordinary bath pruritus is the drying of the skin caused by soap and water and by the dry winter air outdoors and the dry air of heated dwellings. It should therefore be more pronounced in winter than in summer. The case described is an extreme one, probably because of the slight hyperthyroidism. Desensitization is hardly to be hoped for. The itching can be modified or perhaps avoided by using soap and water only on the hands and face, the feet and the body folds. Then the patient should take a colloid bath made with bran, oatmeal or starch. This should be tepid and after it the skin should be dabbed gently until nearly dry, then anointed with 10 per cent borated petrolatum, with rose water ointment or other ointment, or with a lotion, such as the following, originated by Dr. William Allen Pusey:

	Gm. or Cc.	
Liquid petrolatum	120.0	
Oil of rose geranium		
Oil of bergamot		
Oil of lavender	āā	0.1 or more as desired
Sodium benzoate	2.0	
Powdered tragacanth	16.0	
Water	to make	1,000.0

Phenol to 1 per cent may be added if desired, or any other antipruritic such as solution of coal tar.

The colloid bath is made of bran or oatmeal from 1 to 3 pounds to a 30 gallon bath, boiled for a few minutes in a gauze bag, to keep it out of the drains. This bag and the water in which it has been boiled are stirred about in the bath, and the bag gently squeezed. The starch bath is simpler, for no precautions need be taken to keep it out of the drains. It should be stirred up with cold water until it swells and then placed in the bath. The temperature of the bath water should be about 100 F. so that it may soothe, not stimulate. The patient should be taught that baths are not needed so frequently in winter as in summer, for the skin has less opportunity of becoming dirty.

AMMONIA AND RESPIRATORY SYSTEM

To the Editor:—I should appreciate an answer to the following hypothetic problems, all of which have medicolegal significance: 1. Could the exposure to fumes of ammonia gas in a man aged 54 light up a latent or quiescent tuberculosis? 2. What are the effects of ammonia gas on the respiratory tract? 3. It has been stated that ammonia gas never reaches the lungs. Is this a correct assumption? If so, what is the mechanism that prevents the gas from entering the lungs?

M.D., New York.

ANSWER.—1. Possibly yes, if the exposure to ammonia led to purulent catarrhal tracheitis, hemorrhagic bronchopneumonia, peribronchial pneumonia, pulmonary abscess or any prolonged injury of severe nature to the lower respiratory tract. Tuberculosis is not a common result.

2. Ammonia gas chiefly attacks the membranes of the upper respiratory tract, leading to edema, which edema may be delayed. Through reflex action, ammonia attacking the membranes of the upper respiratory tract may lead to cardiac dysfunction, paralysis of the respiratory center in the brain, convulsive movements and the like. Action on the lower respiratory tract is the same, although less ammonia may reach this portion of the respiratory system.

3. When concentrations of ammonia are high, spasm of the glottis prevents the entry of much ammonia into the trachea. On this account ammonia is commonly classed as an "irrespirable" gas. However, under some circumstances some ammonia may reach the bronchi and bronchioles. It may be doubted that any ammonia as such leaves the terminal air sacs and possibly none leaves the ultimate bronchioles. The reason for this is that the ammonia, immediately on contact with surface tissues, is chemically combined. The action of ammonia within the lung is localized exclusively, or almost exclusively, along the bronchial tree.

Council on Medical Education and Hospitals

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Thirty-Fifth Annual Meeting, held in Chicago, Feb. 13 and 14, 1939

(Continued from page 1288)

DR. JULIAN F. DU BOIS, Sauk Centre, Minn., in the Chair

THE FEDERATION OF STATE MEDICAL BOARDS

FEBRUARY 14—MORNING

Does Medical Licensure Procedure Conform to the Accepted Standards of Medical Education?

DR. A. C. FURSTENBERG, Ann Arbor, Mich.: The principal objective of medical education is the preparation of men and women for the practice of medicine. It must constantly change with the advent of new knowledge and new demands of service. It is impossible to prepare a curriculum which possesses permanent values. Growth and improvement in methods of teaching are imperative, with adjustments based on the changing social needs of medical service, and I doubt that medical education is keeping pace.

One hears dissatisfaction expressed on the count that premedical education deals with abstruse learning and has wandered far from its original purpose. Thirty years ago the premedical course was established to give the student a broad general education before he commenced the study of medicine. I doubt that this objective now dominates the picture. Analysis of the premedical curriculum discloses that it is composed largely of specific science subjects. The addition of numerous science studies has pushed the cultural ones out into the periphery of the curriculum. Students contemplating the study of medicine intuitively seek the science subjects, believing that they offer the best preparation for the study of medicine, and frequently they are urged by educators to take advanced courses in biology and chemistry in order that they may start medical education on the highest possible scientific level. I know of several arts colleges where premedical students are urged to study the anatomy, embryology, biochemistry and physiology of man. Such a program, which includes medical subjects, defeats the purpose for which premedical education was designed. Instructors in medical schools complain of this plan, arguing that it taxes their strength and patience to repair the damage done the students by instruction in basic medical sciences presented from the standpoint of the academician rather than from that of the doctor of medicine. Such a program robs the premedical curriculum of its cultural subjects and deprives the student of his only opportunity to obtain a broad general education before he commences to study medicine.

I urge that greater flexibility in the premedical curriculum be promoted, that it be made less stereotyped and that it be opened up liberally to cultural subjects so that it will give the student a wider range of interests. The term premedical is an unfortunate one. It should not represent a course specifically preparatory to the study of medicine. It should give the student a mature intellect and a well disciplined mind and prepare him for any professional study in which he may wish subsequently to engage.

If the present plan of premedical education fails to fulfil its purpose, the burden of criticism does not all rest with the medical schools. Some of it can be charged to the boards of registration. It is to be remembered that the boards have prescribed certain specific science requirements. They have written them into the laws governing the licensure of physicians, and the physician must present credits in these courses before he is certified for the practice of medicine. What about the student who has not pursued the science courses who

decides at the termination of four years of college that he wishes to study medicine? His predicament is most discouraging, because he finds the doors of the medical school closed to him. He is told that he has made his decision too late, that he should have known that he wanted to study medicine when he entered the freshman year in the arts college and that his only recourse is to return to the literary school for two more years of work in the sciences. I am wondering whether a decision of this character absolves the educator from further obligation to the student. Is the student to be penalized for withholding judgment on a matter of such vital importance as his life's work until he has graduated from the arts college at the age of 21? I have interviewed college graduates with excellent scholastic records who have decided that they wished to study medicine but were considered undesirable candidates by admissions committees because they had not completed the so-called premedical curriculum. Many of these students have been striking personalities, brilliant in their college accomplishments and equipped with a broad cultural education but destitute of the science credits which have been prescribed by law and required by medical educators.

All of which leads me to appeal for a less rigid, less stereotyped premedical curriculum, one that will give the student a broad general education before he commences the study of medicine. If the physician finds a knowledge of physics, chemistry, botany and zoology essential to the practice of medicine, then let no one interfere with the present premedical curriculum. If he can get along, as I do and as many of my colleagues do, without a speaking acquaintance with these subjects, then may I beg that a searching consideration be given to a problem of vital importance to the medical profession.

The second cause of dissatisfaction expressed by medical practitioners and the leading educators pertains to the work in the medical school itself and the methods of presenting it to the students. There is a conspicuous lack of integration of the fundamental sciences and clinical medicine. The time honored system of medical training thrusts the student into two years of arduous study of the basic sciences and then abruptly transfers him to a study of the practical clinical problems in the hospital. In short, there is a wide gap between the basic sciences and clinical medicine; the former are divorced from the latter, with the result that seniors and recent graduates are wofully deficient in a knowledge of the fundamental sciences. This plan is open to criticism when one recalls that half of the period of medical training has been devoted to a study of preclinical subjects. The trouble rests in failure to correlate the basic sciences and clinical medicine. It is futile to expect the student to retain a working knowledge of anatomy, for example, if he is divorced from the subject at the termination of the freshman year in medicine. The introduction of some genuine practical problems into the early years of medical training, and the pursuit of the fundamental sciences not for a greater number of hours but throughout the four year period of medical education in close association with clinical and preventive medicine, would mean that on the day of graduation the student was equipped with a knowledge of the basic sciences as serviceable as his knowledge of general surgery or internal medicine. Let us not be consumed by the ambition to recruit academicians and theoreticians from the student body. Let us focus on our objective, that of preparing men and women for the practice of medicine.

What then are the common interests of medical education and the state boards' procedure for licensure? A study of the boards' questions which serve as an index of the examiner's estimate of the young graduate's professional capabilities is revealing. Three distinct types of questions are usually in evidence: (1) the formal memory question, not expected to elicit a practical answer; (2) the less rigid academic question, which calls for both a theoretical and a practical answer and reveals a comprehensive and well integrated knowledge of the problem, and (3) the technical question, which calls for an immediate practical answer on the mechanics or technic of some particular method or procedure.

The following question is an example of the first type, the formal memory question: Define: (*a*) plica vascularis; (*b*) vitelline duct; (*c*) urachus. What is the student going to do with this question? The answer is "nothing" unless he was fortunate enough to turn accidentally, the night before the examination, to the chapters in his textbook which described these terms. An example of the second type of examination question is "Sketch heart and blood vascular system." Here is a question referring to a subject which was commenced in the anatomy course of the freshman year, elaborated on later in the study of physiology, treated sedulously in the pathology courses of the sophomore and junior years and firmly impressed on the minds of the students in their cardiology of the senior year. What will be the character of the student's response? The answer is "good." Here is a subject which was kept alive throughout the medical curriculum; as it progressed from one year to the other, the student acquired interest and understanding and enjoyed the enlightenment derived from a correlation of theory and practice. As a result the material did not fail of lasting recognition at the termination of the senior year. The student's answer to this question reflects in large measure the extent to which he was trained in the medical school. An example of the third type of question is "Describe the technic of lumbar puncture." Even though this question may be a fair one, I doubt that it has a place in the examination of a student who has just completed his senior year in medicine. To perform a lumbar puncture involves mechanical skill, and the mere knowledge of how it should be done falls short of teaching the student how to do it. This operation requires supple and dexterous hands, which can be trained only by experience. Knowing how to do it is not sufficient; the performance demands exercise, which in the present program of medical education has been left to the practical opportunities of the intern year. An intern service in an accredited hospital is one of the legal requirements for practice in many states, and it would seem wise and expedient to delegate the responsibility of teaching technical procedures to the residents and house officers charged with the duties of postgraduate medical education.

Another problem of mutual interest to the boards of registration and the medical schools deals with the medical practice law which requires the student to present a diploma from a recognized college of medicine which has as a minimum requirement a four year course of eight months in each calendar year. This precludes the possibility of utilizing medical credits obtained in a graduate school or acquired in several summer sessions until it is certified in the office of the registrar that the student has been regularly enrolled in a medical school a full academic period in four calendar years. The student who transfers from the curriculum of public health and preventive medicine and the doctorate of philosophy to the medical school is not permitted to use the medical credits acquired in these fields until he has been registered in his school of medicine for the period prescribed by law. This legal requirement has some serious aspects. The extra expense of tuition and maintenance often imposes a severe financial burden on the student. He seeks advanced work in certain courses but is not always favored by the kind of studies best suited to his needs and interests; he dissipates his time and efforts in byways which do not lead in the direction of his objective; in short, he loses his motivation and finally, in despair, is content to make the best of a period of intellectual decadence until time permits him to take his examinations.

I recognize the magnitude of this academic problem, that it is peculiar to most forms of education, but in determining the qualifications of the doctor let us not overlook his training and preparation in the sociological and humanitarian aspects of medicine. Students today are abysmally lacking in these essentials of practice: a knowledge of human conduct and behavior, an understanding of mental and physical reactions to the emotional influences of life, and an appreciation of the variable human capacities for enduring pain and sorrow and resisting adversity and despair. All these factors comprise the very essence of medical practice. Does the medical student know that most of the practice which he anticipates will consist of patients experiencing some social, economic, moral or religious

conflict, that their physical ills will be a reflection of some emotional state and that drugs and operations will not cure them? From the beginning of premedical education until graduation, and beyond, the training of the doctor is predominantly in the organic sciences. A pain in the head is the result of sinus disease, brain tumor or cerebral arteriosclerosis, and if the student cannot find an organic basis for the headache he loses interest and passes on to his next assignment. No one has ever attempted to impress on him that the headache, in all probability, is due to an emotional conflict as important as an organic disease. Medical education has overlooked and is still overlooking this tremendously important field of medicine.

Examination Results Before Massachusetts State Board of Registration in Medicine

DRS. E. A. KNOWLTON, Holyoke, Mass., and STEPHEN RUSHMORE, Boston: The medical practice act of Massachusetts differs from the acts of all the other states. It provides for one board of seven physicians to examine and license persons who wish to practice the art of healing. There are no secondary boards, such as there are in many states, to license osteopaths, chiropractors, neuropaths, homeopaths, eclectics and whatnot to practice their respective cults. There are two boards which might be considered nonprofessional, one in optometry and the other in chiropody, but persons who wish to treat the sick must be licensed by the one board, the State Board of Registration in Medicine. Excluded from this board are physicians who are in any way a part of a faculty of a medical school, and a majority of the board members may not be members of any one chartered medical society. But the great difference between the Massachusetts act and the acts of other states is the requirement that any graduate from a legally chartered medical school must be accepted for examination. As a result Massachusetts is a great gathering place for graduates of the so-called nonapproved schools, who outnumber those from the approved schools about two to one. A great majority of these applicants fail in the examinations but still they come, year after year.

I have been making a statistical study of the end results of the Massachusetts examinations for 1937 and have prepared charts to present the results. The board is compelled by law to conduct examinations by the conventional written tests and to examine in seventeen subjects. As a result of my study I think that all the schools approved by the Council on Medical Education and Hospitals of the American Medical Association are graduating physicians equally well prepared to care for the sick and to deal with the health problems of the country. It is hard, however, to draw comprehensive conclusions. It is apparent that persons in the highest ranking fourth from the nonapproved schools are better qualified to meet a written examination than those in the lowest ranking sixth from the approved schools. The Massachusetts board has been condemned by the profession at large for licensing so many graduates from nonapproved schools. It has been as severely criticized by the officers of some of the approved schools for the high number of failures among their graduates. The question has often been asked, and I know the board members have often asked one another, whether the 26 per cent of applicants from nonapproved schools who have been licensed are better qualified to practice than the 18 per cent of graduates from the approved schools who have failed to pass and have not been licensed. There are, however, far too many applicants from both types of schools who receive exactly 75, a minimum passing mark.

I am not proud of the method of conducting examinations, which treat far too many subjects. The board members are not teachers or research workers. When the legislature changes the medical practice act so that the educational background of the applicants may be considered and some practical or oral test of their qualifications to practice may be used, the results of the examinations will not be so far out of step with those in other states.

DISCUSSION ON PAPERS OF DR. FURSTENBERG AND DRS. KNOWLTON AND RUSHMORE

DR. J. EARL MCINTYRE, Lansing, Mich.: Dr. Furstenberg has expressed excellent ideas. I have been of the opinion that premedical requirements are dogmatic and biased, too severe. I believe that the work leading to the bachelor's degree in liberal arts is as important as preparing the boy or girl for the medical school, if not more important, because I believe that it provides a broader background, better cultural education. Boards that have the power to fix a standard of both premedical and medical education should give thought to this point. I think that in the future changes which would be for the benefit of the coming generation should be considered.

DR. ERWIN SCHENK, Keokuk, Iowa: The program of medical education has not crystallized; it is so large that no one has caught up with it. The teaching force is not prepared to give the basic science work, and the deans are not high enough to coordinate the work that is going on in their institutions. Some of the latter aim to improve the situation by adding more years of study, but many students are like pitchers—you fill them full and whatever more you pour into them runs over the top. It will be necessary to exercise much more care in the acceptance of applicants by medical schools. The capacity is about so much in too many persons. The best way to cull such persons is to grade the colleges.

DR. A. S. BEGG, Boston: The deans are in a difficult position. They are pushed from below by the attitude of the colleges; they are pushed on one side by the faculty and its demands and on the other side by the student and his wishes, and they are pushed from above by the qualifying examinations. The correlation mentioned by the first speaker is being attempted in many places. In Boston University School of Medicine, clinical correlation exercises are started in the first year. A good many exercises are given in connection with the preclinical sciences by clinicians, who use the information the student has acquired to show him how it applies in medicine. There was an exercise not long ago called eighteen hearts. That happened to be the number of subjects in the dissecting room. The eighteen hearts were brought to the amphitheater, a pathologist rendered a report on each one and then a cardiologist discussed the results of the pathologist's examination. In one case the pathologist said "I suspect that you are going to find small kidneys." The instructor's job after the exercise was to keep the students from going in and taking out the kidneys to see whether he was right. In an exercise on the genito-urinary system the instructor told the students about roentgenograms that show double ureters and explained these on an embryologic basis; the students went back into the laboratory and were much interested in studying the very thing that they had been studying the preceding week, because here was a man who was making his daily bread by knowing such facts. I am not much worried about the waste of time on the part of the brilliant student. He finds other things to do. I have seen few who have been adversely influenced by long exposure to the medical curriculum. When one looks at the results of the examinations in Massachusetts, one is amazed and realizes the weakness of the whole system. I should like to recommend to the Federation of State Boards that it appoint a subcommittee to study the technics and content of state examinations, because I think they are very uneven. It is too bad that in Massachusetts so many persons must be examined in the course of a year. I hope that in 1941 this will be changed a little, but at the same time there ought to be legal provision for a really practical examination of those who come up for licensure.

DR. F. H. MAGNEY, Duluth, Minn.: You have heard the law and the setup in Massachusetts. Let me briefly state the setup in Minnesota. A basic science board eliminates a large number. Candidates for the medical board are mostly University of Minnesota graduates. The university I think has about 600 applicants each year, from which about 100 are selected. The university works well with the medical profession and the Minnesota State Medical Association, so its methods of teach-

ing are much in accord with medical practice. The other candidates are men who are working in the Mayo Foundation at Rochester, which is affiliated with the university. They come from the university medical schools of this country and Canada and they also are a picked group. About the only older men, who have been out of school for any length of time, are men who are put on the faculty of the university. The state board has the discretion of stating what types of candidates or what schools are recognized, as compared with the Massachusetts board, by which any school which is legalized or licensed must be recognized. Minnesota recognizes only class A schools. It is a question whether the board should be too critical in its examinations when the candidates are of such high caliber. A candidate is failed occasionally, but there is no reason why the percentage should be high.

DR. L. J. KOMINSKY, Texarkana, Ark.: I was glad to know that Massachusetts confesses its shortcomings from the medical standpoint. I find through my experience on the state board that there are two branches in which the students are quite lacking, materia medica and therapeutics. Every day the physician is confronted with detail men who know nothing about medicine but who tell him how to treat disease with the remedies put out by their houses. If every doctor had in his office the U. S. Pharmacopeia, the National Formulary and New and Nonofficial Remedies, he could find out whether the preparation in question was in one of these three. If a preparation is not, it should be let alone. I have told that to the young men before the state board in the past two years. In Arkansas, after a lot of tribulations, a basic science board has been established. I want to say for the University of Minnesota that last November one of its graduates, who is now a captain in the Army and Navy General Hospital, made the highest grade that has been made in Arkansas in the past eight years.

DR. G. M. WILLIAMSON, Grand Forks, N. D.: The remarks made by the last speaker are very apt. The universities are not teaching materia medica and therapeutics. Dr. Furstenberg's paper is one of the best I have ever heard. The university medical schools are teaching too scientifically and are not practical enough. The board in North Dakota examines only a small number, and the men are fairly well known before they come up for examination. A candidate either satisfies the board or doesn't satisfy the board. Even if he makes 90 or 95, if he is not the right type to turn loose on the public, he is so notified. One of the best men ever examind, as far as grades were concerned, it would have been a crime to license, because he didn't know anything. He was the most unpractical person ever examined by the board. What can be done with such men? I believe that it would be a good plan to have some of the deans and members of the council at these meetings, to have more plain talk and not to let one group do all the talking and tell us what to do, because the members of the state boards have to pass on the candidates later.

DR. T. J. CROWE, Dallas, Texas: I don't think any of us can know too much about medicine. I am against any attempt to reduce the premedical or medical qualifications. I believe that any man who wants to call himself a specialist should have at least from three to five years of intensive training in an institution devoted entirely to the subject which he is going to take up. I think the board should do something about that phase of the matter. It can be controlled through the hospitals. Now, about the examinations. There are advisory committees and then advisory committees of advisory committees. Why don't we talk about standardizing examinations? Why don't we talk about standardizing with reference to reciprocal relations and with reference to the credits that should be allowed a man who has been engaged in active practice? I should like to have settled, if possible, what credit shall be given the man who has been in active practice and is required to take a state board examination.

Citizenship and Medical Licensure

DR. J. E. MCINTYRE, Lansing, Mich.: This article appeared in full in THE JOURNAL, March 18, page 1075.

Legal Status of the Intern

DR. FRED E. CLOW, Wolfeboro, N. H.: This article will appear in full in THE JOURNAL.

DISCUSSION

DR. FRANK M. FULLER, Keokuk, Iowa: There was no mention in this paper of the type of internship that is now known, at least locally, as a voluntary internship. In order that the term may be understood I will say that men from foreign countries are being sent into various institutions by miscellaneous groups who have enough money to assure the government that their protégés are not going to become public charges. Such foreign physicians are being distributed. I say that because the problem has come up in Iowa, where men have come into the state university hospitals as voluntary interns. This means that, after the university has had its full quota of internships assigned, men are sent in with expenses paid to the extent of $600 a year, as voluntary interns. What is the legal status of interns of this type? When they get through, the board has to have a certificate from the dean or officer of the hospital that they have completed an internship. After having completed a year's internship in Iowa, they are eligible to licensure in the state. The board is concerned as to just how it is going to handle these so-called voluntary internships. To my mind there isn't any such thing. An intern is an intern whether he is voluntary or involuntary. I am asking this in order that some light may be thrown on the problem, which no doubt is going to be more extensive. I have been trying to find out where the idea of voluntary internships originated and who is supporting the unfortunate persons who are being driven out of their own country and brought in here. I should like to know how extensive is the movement toward establishing voluntary internships throughout the country.

DR. EDWARD A. KNOWLTON, Holyoke, Mass.: I did not know until I heard Dr. Clow read his paper that Massachusetts is the only state which licenses interns. I thought that Massachusetts was the last to do anything modern in medical licensure. It has worked out very satisfactorily. There are two types of license, one for the student intern and one for the graduate who is an intern. The licensure provides the board with a registry of all the interns throughout the state. When an intern appears at a hospital, the first thing asked him by the hospital authorities is "Let me see your license."

DR. J. EARL MCINTYRE, Lansing, Mich.: In Michigan the attorney general has ruled that the board has the power of fixing a definite internship period as an educational requirement, and the state has a twelve months rotating internship. The attorney general also has ruled that on completion of this internship, any who practice medicine, either within or without a hospital, thereafter must be registered and licensed by the board. Licensure is therefore required of all second year interns and residents. The attending staff physician is thus not responsible for the intern's or resident's act; the hospital is not responsible because such intern or resident has all the prerogatives of any other doctor of medicine within the state. In other words, the attending physician cannot delegate his authority to practice medicine. He cannot delegate any authority to the intern, resident physician, nurse or technician. This has been a means of solving that particular problem in Michigan.

DR. FRED E. CLOW, Wolfeboro, N. H.: I did not mention in my paper that there are records in New Hampshire of twenty-three malpractice suits brought against interns. Most of these cases, of course, came to nothing, but enough have had to be settled to disturb the board. Apparently the lawyer has found that he cannot recover from the hospital except in rare instances, and he has learned to go back of the hospital to the young man who is the cause of the alleged malpractice. These suits have a nuisance value at least, so that there is often involved the payment of some money in order to clear the young man. When he is an unlicensed person, he is put in an extremely vulnerable position. I cannot answer Dr. Fuller's question. Voluntary internship is not known, at least by that name, in my part of the country, and I do not know of any men who have been placed in hospitals under such circumstances.

The Objectives, Aims and Activities of the Commission on Graduate Medical Education

DR. ROBIN C. BUERKI, Chicago: The Commission on Graduate Medical Education is still less than a year old, and obviously it is not prepared as yet to give specific answers to any of the questions that have been raised. I should like, however, to present some of these questions and suggest possible answers. In a statement of the scope of the work of the commission, the chairman said in part:

"The Commission on Graduate Medical Education will undertake the formulation of the educational problems and principles involved in the continuation of medical training for a period of years after graduation, in the adequate training of specialists and in making recommendations for those in practice, general and limited, to keep abreast of new developments in diagnosis, treatment and prevention. It is the opinion of the commission that these phases of graduate medicine are closely related and should be regarded broadly as parts of a single problem.

"The educational problems of the internship need definition in the larger concept of medical education because of the great confusion that now exists among physicians, hospitals and medical faculties regarding this vital, though frequently unsatisfactory, phase of training. There is need of integrating the hospital training with the undergraduate course and of making it more effective as a preparation either for general practice or for advanced training for a specialty.

"Little attention has yet been given to the opportunities for training for specialization of the large number of practitioners who are otherwise qualified and desire to become fully equipped in a limited field of practice. Sound plans which will meet individual conditions and permit these physicians to secure an adequate preparation in a special field must be worked out.

"In recognition of the need of a study of the whole situation in graduate and postgraduate medical training, it seems desirable that there be set up a group to mobilize the best current opinions and experience and to formulate principles and standards of training which may be of help in setting up programs of instruction. Such a group should comprise representatives of the profession, the specialty boards, the hospitals, the medical schools and the state regulatory bodies familiar with these problems. It would develop standards of training which would be of help to the Association of American Medical Colleges, the Council on Medical Education and Hospitals of the American Medical Association and other agencies concerned with the inspection and evaluation of facilities. There should be no duplication of effort or conflict with such agencies.

"The Advisory Board for Medical Specialties is more representative than any other body of the different interests involved and it was felt that it should create a group to study the whole problem; hence its action in Atlantic City on June 6, 1937, creating the Commission on Graduate Medical Education.

"It was understood that the commission would concern itself primarily with those problems which are common to all the specialty boards and organizations dealing with the different aspects of graduate medicine and would not attempt to accredit or evaluate facilities or perform other administrative functions now carried out by the Association of American Medical Colleges, the American Medical Association, the American College of Surgeons and other administrative agencies. Obviously the material developed would be made available to the interested groups."

The director of study began work March 1, 1938. In a discussion of the whole problem with more than 400 persons from all parts of the country, emphasis has been placed on the fact that this is not a survey. Almost without exception the men visited were in enthusiastic accord with the aims of the commission, feeling that lack of adequate training and opportunities for continued education constitutes one of the greatest problems confronting the medical profession today.

There seems to be a definite feeling that the internship should be more closely related to the undergraduate years and should be considered as such by the staffs of hospitals and the faculties of the medical schools. Partly because almost all medical students after graduation serve as interns in hospitals and partly because medical schools do not feel that at present they have adequate control over the type of internship offered, it seems to be an open question as to whether or not an internship should be required for graduation. The general feeling is that the average internship is not satisfactory from an educational standpoint, but there is considerable divergence of opinion as to how the educational content of the internship shall be improved.

The vast majority of the internships offered are rotating services; from 1934 to 1938 these increased from 4,569 to 5,697. In spite of the fact that recently there was a decrease in the number of straight internships from 781 in 1934 to 442 in 1938 and an increase in the number of mixed internships from 853 in 1934 to 1,212 in 1938, there is still a rather strong feeling on the part of some authorities that a straight service is desirable. A rather large group of men feel that even in a rotating internship some of the more highly specialized services should not be offered to interns.

There seems to be almost complete unanimity of opinion that a residency of three or more years is the ideal way to prepare a man for the practice of his chosen specialty, nor does there seem to be any major disagreement concerning the ruling of the various specialty boards that a portion of the residency shall contain work in the medical sciences. The majority of the specialty boards feel that such work should train the resident to approach his specialty from the point of view of the scientist and need not necessarily make him more proficient in all the basic science courses; the men in the basic sciences as a whole feel that neither the budgets nor the staffs of their departments are adequate to offer this work and suggest the possibility of training individual clinicians who are members of the various clinical departments and who in turn can give this work to their own residents or, in large groups, to the prospective candidates for certification in their specialty.

There is considerable agitation to have more opportunities available for men already in practice to develop proficiency in their specialty. The general reaction is that short courses, if given for graduates to perfect themselves in a specialty, are not educational in fact and do not train the man to be competent in his chosen field. There is a definite feeling, and figures substantiate it, that the good residencies are too few to produce enough trained men to meet the needs for the replacement in and the growth of the specialties. It is gratifying to note, however, that the number of all residencies has increased by 50 per cent in the last five years, from 2,373 in 1934 to 3,492 in 1938, and that the number of residencies of three or more years in length has trebled in the same period, having increased from 332 in 1934 to 1,092 in 1938. Many of these residencies are not really satisfactory.

The solution of the problem of postgraduate medical education for the general practitioner is a most difficult problem. After the physician has become recognized in his specialty, his contact with national societies and his willingness to read in most instances keeps him abreast of the advances in his specialty, but this is not true in the main of the general practitioner. Some persons have the definite feeling that the only way to keep the rank and file of the profession abreast of the advances in medicine is to give limited licenses, even though they recognize the difficulties involved in such a suggestion. It has also been suggested that a specific amount of postgraduate work be essential for continued membership in the local county medical society.

After eleven months of travel from one end of this country to the other, I feel sure that the medical schools must take more than an academic interest in the building and operation of a coordinated program of medical education that will follow their students from the time of graduation until they retire from the active practice of medicine. In this broad and comprehensive program hospitals will play an increasingly important part, but they must await the constructive leadership that only the medical schools can supply. It is obvious that the solution which I am proposing involves a large expansion of thought and activity on the part of the medical schools. Leadership in meeting this great series of problems must come primarily from those who have heretofore carried the major responsibility for medical education. No other group has the richness of experience in medical education that medical educators have.

(To be continued)

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, April 1, page 1288.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS Parts I and II. Medical centers having five or more candidates desiring to take the examination, May 1-2 (Part II only—limited to a few centers), June 19-21, and Sept. 11-13 Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Oral* examinations for all candidates, St. Louis, May 13-14 *Written* Various places throughout the United States, Sept. 9. Applications must be filed by July 11. *Oral* Part II Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY Philadelphia, Oct. 30-Nov. 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE *Written* Various sections of the United States, Oct. 16 and Feb. 19. Formal application must be received before Aug. 20 for the Oct. examination and on or before Jan. 1 for the Feb. examination Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY General oral, clinical and pathological examinations for all candidates, Part II examinations (Groups A and B) will be held in St. Louis, May 15-16 Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY *Written* Various cities throughout the country, Aug. 5 *Oral* St. Louis, May 15 and Chicago, Oct. 7. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY St. Louis, May Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago

AMERICAN BOARD OF OTOLARYNGOLOGY St. Louis, May 12-13 and Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha

AMERICAN BOARD OF PEDIATRICS Cincinnati, Nov. 15 Appointments must be made before July 15 Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY Chicago, May 13 Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY St. Louis, May 11-14 Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY *Part II* New York, May 8 and May 9 Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia

AMERICAN BOARD OF UROLOGY White Sulphur Springs, W. Va., May 26-28 Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis

Vermont Endorsement Report

Dr. W. Scott Nay, secretary, Vermont State Board of Medical Registration, reports nine physicians licensed by endorsement from July 25 through Dec. 17, 1938. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
Johns Hopkins University School of Medicine		(1927)	N. B. M. Ex.
Harvard University Medical School		(1929)	N. B. M. Ex.
Tufts College Medical School		(1937)	New Hamp.
Cornell University Medical College		(1924)	New York
Hahnemann Med. College and Hospital of Philadelphia		(1937)	Delaware
University of Vermont College of Medicine		(1937, 4)	N. B. M. Ex.

California October Examination

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held at Sacramento, Oct. 18-20, 1938. The examination covered nine subjects and included ninety questions. An average of 75 per cent was required to pass. Sixty-four candidates were examined, fifty-four of whom passed and ten failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
College of Medical Evangelists		(1937)	75.1, (1938) 75.9, 78, 80.2, 81, 81.1, 83, 86, 86.3, 86.6, 86.8
Stanford University School of Medicine		(1938)	83.9
University of California Medical School		(1938)	80.6, 85.1
Loyola University School of Medicine		(1938)	80.3
Northwestern University Medical School		(1937)	82.3, (1938) 79.9, 86.7,* 88
Rush Medical College		(1937)	85.7, (1938) 85.4
School of Medicine of the Division of Biological Sciences		(1937)	85.2
University of Illinois College of Medicine		(1937)	79.9
University of Kansas School of Medicine		(1937)	87.1
[illegible] l of Medicine		(1938)	81

Hawaii October Examination

Dr. James A. Morgan, secretary, Board of Medical Examiners, Territory of Hawaii, reports the oral and written examination held at Honolulu, Oct. 10-13, 1938. The examination covered ten subjects and included eighty questions. An average of 75 per cent was required to pass. Ten candidates were examined, nine of whom passed and one failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Stanford University School of Medicine		(1936)	79.1
Loyola University School of Medicine		(1937)	82.4
Northwestern University Medical School		(1936)	87
Rush Medical College		(1935)	87.7
University of Louisville School of [illegible]		[illegible]	81.7
Washington University School of [illegible]			82.3
Pennsylvania Medical School, St Shanghai	(1935) 78.3,	(1938)	79
Woman's Christian Medical College, Shanghai		(1938)	77.8

School	FAILED	Year Grad	Per Cent
Nippon Ika Daigaku, Tokyo		(1937)	40

Five physicians were licensed by endorsement from July 27 through September 24 after an oral examination. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
Rush Medical College		(1934)	N. B. M. Ex.
Tulane University of Louisiana School of Medicine		(1937)	N. B. M. Ex.
University of Michigan Medical School		(1932)	N. B. M. Ex.
Washington University School of Medicine		(1933)	N. B. M. Ex.
Hahnemann Med. College and Hospital of Philadelphia		(1935)	N. B. M. Ex.

Kentucky December Examination

Dr. A. T. McCormack, secretary, State Board of Health of Kentucky, reports the written examination held at Louisville, Dec. 6-8, 1938. The examination covered eleven subjects and included 110 questions. An average of 70 per cent was required to pass. Two candidates were examined, both of whom passed The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Louisville School of Medicine		(1938)	79
Temple University School of Medicine		(1937)	76

Fourteen physicians were licensed by reciprocity from September 2 through December 19. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
College of Medical Evangelists	(1936),	(1938)	Michigan
Tulane University of Louisiana School of Medicine		(1936)	Louisiana
Johns Hopkins University School of Medicine		(1935)	Maryland
University of Michigan Medical School		(1933)	Michigan
University of Minnesota Medical School		(1934)	Minnesota
Ohio State University College of Medicine		(1936)	Ohio
University of Cincinnati College of Medicine	(1932),	(1935)	Ohio
Western Reserve University School of Medicine		(1937)	Ohio
Vanderbilt University School of Medicine	(1932),	(1935), (1936), (1937)	Tennessee

Indiana Reciprocity and Endorsement Report

Seventy-one physicians were licensed by reciprocity and two physicians were licensed by endorsement during 1938 by the Indiana State Board of Medical Registration and Examination. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine	(1935),	(1936)	Arkansas
University of Colorado School of Medicine		(1936)	Colorado
George Washington University School of Medicine		(1935)	Maryland
Howard University College of Medicine		(1936)	Tennessee
Loyola Univ. School of Med	(1918), (1932), (1935),	(1937)	Illinois
Northwestern University Medical School		(1923)	Mississippi, (1926), (1936) Michigan, (1935) Missouri, (1936) Ohio, (1932), (1933), (1936) Illinois
Rush Medical College		(1925)	Kansas, (1935) Ohio, (1936) Utah, (1928), (1930), (1932, 2), (1936, 2) Illinois
School of Med of the Division of [illegible]		[illegible]36)	Illinois

Mississippi December Report

Dr. Felix J. Underwood, secretary and executive officer, Mississippi State Board of Health, reports nine physicians licensed by reciprocity at the meeting held in Jackson, Dec. 8, 1938 The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
University of Louisville School of Medicine		(1910)	Kentucky
Tulane University of Louisiana School of Medicine		(1938)	Louisiana
University of Maryland School of Medicine and College of Physicians and Surgeons		(1916)	W. Virginia
University of Pennsylvania School of Medicine		(1936)	Texas
Meharry Medical College		(1935)	Tennessee
University of Tennessee College of Medicine		(1936), (1937)	Tennessee
Vanderbilt University School of Medicine		(1934)	Tennessee
University of Texas School of Medicine		(1921)	Texas

Book Notices

Shock and Related Capillary Phenomena. By Virgil H Moon AB, M Sc, M D., Professor of Pathology, Jefferson Medical College, Philadelphia. Cloth. Price, $3.50. Pp. 442, with illustrations New York Toronto & London: Oxford University Press, 1938.

The purpose of the book is to present the subject as a pathologic entity. The author states that the major advances in solving the shock problem have been made by physiologists and surgeons, while the contributions made by pathologists have been negligible. In order to remedy this defect, the author attempts to discuss shock as he would any other pathologic condition The book begins with an excellent review of current knowledge concerning the capillaries; their distribution, function, reactions permeability and local capillary phenomena associated with the action of histamine, with inflammation and so on. Then follows a brief but good review of the theories concerning shock The remaining portion of the book, with the exception of an appendix on practical considerations, is devoted to a presentation of the pathologic processes and morphologic changes in shock, to the evidence for the special theory favored by the author, that of traumatic toxemia, and to an attempt to correlate the pathologic processes and morphologic changes in traumatic shock with those found in many other pathologic conditions, including anaphylactic shock, burns, edema and terminal pneumonia, on the basis of primary injury of the capillaries with subsequent loss of circulating fluid The book is written with the spirit of a crusader Few readers familiar with the present status of the knowledge of shock will disagree with most of the material presented The author has summarized in a masterly manner the opinions and conclusions of numerous investigators employing diverse methods of approaching the many different phases of the problem Such a unanimity of approval will probably not be given the author's considerations of the toxemia theory and his apparent belief that the shock problem has been definitely solved The book is recommended for those desiring a well written and stimulating review of the known facts concerning capillary phenomena Pertinent references and a suitable index are given The print is large and easy to read.

A Study of Asbestosis in the Asbestos Textile Industry. By Waldemar O. Dreesen, Passed Assistant Surgeon, and others From the Division of Industrial Hygiene, National Institute of Health Prepared by direction of the Surgeon General U. S. Treasury Department, Public Health Service Public Health Bulletin No 241. Paper Price, 20 cents Pp 126, with 64 illustrations. Washington, D C: Supt of Doc, Government Printing Office, 1938

This complete study of the asbestos industry made by the Division of Industrial Hygiene of the United States Public Health Service ranks with the best of the industrial studies that this group has produced Initiated by the State Board of Health and by the Industrial Commission of North Carolina, the objectives of the study were to determine the effects of continued inhalation of asbestos dust, identifying the various processes which produce the dust, and recommending at the same time the indicated engineering improvements to control the pollution of the atmosphere. The study endeavors to determine what concentrations of asbestos dust can be safely borne The report begins with a description of the various processes in which asbestos is used in combination with cotton to fabricate various textiles A brief comparison is made with the similar industry in Great Britain. An analysis of the various occupations involved was made and dust samples were collected by the standard impinger method with reference to each occupation. It was demonstrated that it was possible to reduce the dust concentration below five million particles per cubic foot In all, about 550 asbestos workers received thorough physical examinations, including a carefully worked out occupational history. Both the x-rays and the fluoroscope were used and the observations were carefully tabulated The investigators classified the asbestosis cases on the basis of x-ray interpretations in three stages, although pointing out that it is not practicable to establish a sharp line of demarcation between the stages. Of a total of 445 workers examined with x-rays, seventy-three were diagnosed as having asbestosis. It should be remembered that all examined in the groups were individuals who were working daily. Including

both workers still on the job and those who had been discharged or laid off, 27.5 per cent were found to have asbestosis. This figure might be compared with the results of the silicosis studies at Picher, Okla., where 21.3 per cent had silicosis, and the study of anthracite miners by this same group, among whom the prevalence of anthracosilicosis was 23 per cent. The report includes a chapter on pathology. The numerous illustrations, both reproductions of slides as well as lung specimens and x-ray films, are excellent. This is an admirable report, is a substantial contribution to the general subject of pneumoconiosis, and will go a long way toward clarifying some of the doubtful aspects of asbestosis.

The Practical Applicability of the Cardio-Pulmonary Function Test. By Gustav Nylin. Acta medica scandinavica, Supplementum 93. Paper. Pp. 24, with 25 illustrations. Stockholm, 1938.

In attempting to evaluate the functional capacity of the heart, various investigators have tried many types of tests. Perhaps the most valuable functional test is that which measures the energy cost of physical exercise. Among such tests is the one developed by Nylin. The results of his experience are presented in this monograph. The test used by him consists of three degrees of exertion on a pair of semicircular stairs each having six steps going up and six going down. The effect of these exercises on the oxygen consumption was determined by comparing the basal rate with the increased rate occurring from two to five minutes after completing the exercise. Both metabolic tests were run with the patient reclining in bed. As the result of an experience on 265 normal persons and twenty-two patients with various forms of cardiac and pulmonary disease, the author states that this test gives an estimate of the functional capacity of the heart when the state of the pulmonary system is taken into account. It is unfortunate that he uses the term "relative oxygen debt," because a sample of the excess oxygen consumption of exercise need not necessarily be a measure of the entire extra oxygen consumption caused by the exercise. Nevertheless, viewing it entirely from its practical utility the method developed seems promising and deserves further trial. The presentation is simple and somewhat superficial. It should nevertheless be appealing to those interested in objective methods of estimating cardiac capacity and cardiac reserve. While it is meritorious to seek objective methods of estimating cardiac capacity, no method will turn out to be as practically efficacious as a careful inquiry by the physician into the ability of the patient to do his daily activities and to meet the extra strains which he is forced to cope with. There is no short cut to a careful, history. It is true, however, that the discipline placed on the clinician by information derived from proper objective tests may at times be invaluable.

Biokhemichni zmini krovi i spinnomozkovoï ridini pri uremiï. [By] M. L. Ertukhova. [Biochemical Changes in Blood and Cerebrospinal Fluid in Uremia.] Paper. Price, 6 kopecks. Pp. 166. Kiev: Vidavnitstvo Akademiï Nauk URSR, 1938.

The author studied biochemical variations in the blood and the cerebrospinal fluid of thirty-nine uremic patients. The studies included the alkali reserve, most of the nitrogenous fractions of the protein metabolism ordinarily determined in the blood, the inorganic phosphorus, K, Ca, the chlorides, Na, cryoscopy, sugar, cholesterol and lactic acid. The simultaneous study of the blood and the cerebrospinal fluid is valuable from both the diagnostic and the therapeutic points of view. Thus, data obtained from the group of patients suffering from "azotemic" uremia, cases characterized by the disturbance of the nitrogen excretory function without a disturbance of the acid excretory function and without any manifestation of disturbance of the permeability of the hemato-encephalic barrier, permitted the author to draw the conclusion that the process can be reversed by elimination of the causes giving rise to accumulation of nitrogenous waste products, as, for example, infection or dietetic disorder. In another group in which, along with the azotemia, there were observed a sharp fall in the alkali reserve and manifestations of the disturbance of the permeability of the cell membrane, specifically the hemato-encephalic barrier, the prognosis was unfavorable and treatment powerless. The group with acute convulsive uremia justifies the assumption of cerebral edema and the use of spinal puncture. The author's thesis is that comparative study of the biochemical changes and the clinical manifestations rather than the search for the hypothetic uremic toxin will lead toward the solution of the essential pathogenesis of uremia.

This suggestive contribution to the clinical subject of uremia is written in the Ukrainian. It contains summaries in Russian and English.

Babies are Human Beings: An Interpretation of Growth. By C. Anderson Aldrich, M.D., Associate Professor of Pediatrics, Northwestern University Medical School, and Mary M. Aldrich. Cloth. Price, $1.75. Pp. 128, with 5 illustrations. New York: Macmillan Company, 1938.

This book, written by a pediatrician and his wife, presents the problem of growing up from the point of view of the child. This is indicated by various chapter headings, such as "The Baby Dilemma," "The Baby Responds to the World" and "The Baby's Way of Eating." Emphasis is laid especially on the response of the infant and on ways and means of making his environment as helpful as possible in developing his own personality and in fitting himself into this world without sacrificing his enthusiasm and energy, which is so evident at 2 and 3 years of age and which so often is lost later on. The volume should be helpful in solving many of the problems which the physician meets, not so much by the specific advice given in a particular situation as by serving as a basis for working out problems. For parents it should prove of great value. It is a book not only to be read but to be reread and studied, chapter by chapter, by both mother and father. It will give the parents an insight into what their offspring is trying to accomplish in growing up and how they as parents can help in making it possible for him to reach maturity with the least number of harmful bumps and with his native enthusiasm intact.

The Principles and Practice of Perimetry. By Luther C. Peter, A.M., M.D., Sc.D., Professor of Ophthalmology in the Graduate School of Medicine of the University of Pennsylvania, Philadelphia. Fourth edition. Cloth. Price, $4.50. Pp. 331, with 227 illustrations including 5 colored plates. Philadelphia: Lea & Febiger, 1938.

This book has long been of established value to the ophthalmologist and practitioner in allied branches of medicine. The new edition is revised and enlarged with new illustrations and tables to clarify the text and points of difference. As in former editions, the various phases of perimetry are presented in logical sequence. Part I consists of a brief but adequate description of the anatomy and physiology of the visual pathway. Part II describes the extent of the normal visual fields and physiologic principles which govern and influence them. Part III outlines in a clear and detailed manner the method and technic of taking fields. The various instruments are described. Part IV discusses the general pathology of the visual field. The special pathology of fields is dealt with in Part V. In part VI the fields in functional nervous disease is discussed. A good bibliography is added for those who are interested in various problems which perimetry presents.

Urology. By Daniel N. Eisendrath, M.D., Consulting Urologist to the American Hospital, Paris, France, and Harry C. Rolnick, M.D., Attending Urologist, Michael Reese, Mt. Sinai, and Cook County Hospitals, Chicago. Fourth edition. Cloth. Price, $10. Pp. 1,061, with 762 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1938.

This is an excellent textbook for students and a valuable manual for the general practitioner. The personal experience of the authors is apparent and their therapeutic and operative recommendations represent the standard methods of today. Many of the illustrations have been selected from American and European sources. The original illustrations for this edition have also been well chosen. The chapter on neurogenic dysfunction of the bladder will be well received. Urology in the female is adequately presented in a single chapter. Consideration of the etiologic factors of dilatation of the ureters and renal pelves in pregnancy is taken up under three possible headings: (*a*) mechanical, (*b*) muscular atony resulting "from the action of either hormones or of toxins on ureteral and renal pelvic musculature with resultant atony," and (*c*) mixed origin, viz. the resultant of the chief factor of atony and of compression by the uterus as a secondary cause. While this subject is still a question and various points of view have been expressed in both clinical and experimental contributions

to the subject, recent experimental work would seem to have demonstrated that the dilatation of the upper part of the urinary tract during pregnancy is primarily due to hormonal influence. An occasional typographic error appears, as in the last sentence on page 517. As a whole this book can be heartily recommended and it ranks high in the category of available textbooks for teaching in medical schools. Its broad scope and excellent index will make it a valuable reference work for the specialist in urology. Many references to the earlier editions appear in recent periodical literature of urology in the English language.

Minor Maladies and Their Treatment. By Leonard Williams, M.D. Seventh edition. Cloth. Price, $3.75. Pp. 439. Baltimore: William Wood & Company, 1937.

This edition of a work first published in 1906 has been revised and keeps pace with the discoveries and change in practices in the treatment of minor maladies, including coughs, colds, sore throats, indigestion, constipation, diarrhea, neuralgia, headaches and minor glandular disturbances, and concludes with chapters on general health and treatment in advanced years. While the therapeutic methods suggested at times do not conform with the generally accepted beliefs, the methods employed are satisfactory and will usually be found beneficial. Each subject is considered with sufficient thoroughness to aid in assuring adequate therapy. The book will continue to find its field of usefulness.

The Etiology of Trachoma. By Louis A. Julianelle, Chairman of the Trachoma Commission, Washington University, St. Louis. Cloth. Price, $3.25. Pp. 248, with 13 illustrations, including 10 plates. New York: Commonwealth Fund; London: Oxford University Press, 1938.

Among other things, this book contains a summary of the studies in trachoma that have been in progress in the Oscar Johnson Institute of Washington University for the past eight years. Almost all of the material has appeared at various times in the journals of ophthalmology and as such is familiar to students of the subject. In the eleven chapters of the book the epidemiology, causation and infectivity of trachoma are discussed at some length, after which the text swings into technical descriptions of the bacterial flora of the disease, inclusion bodies and the virus aspect. The conclusion is that "the infectious agent of trachoma is a virus of remarkable frailty, succumbing before physical and chemical agents tolerated by numerous other bacterial and viral agents." A thorough bibliography and index are appended. The book work is good and the illustrations are excellent. The monograph represents a large amount of work, especially of a bibliographic nature, and as such is of great value from a reference standpoint.

Jan Ev. Purkyně 1787-1937; Sborník statí k 150. vyroči narození českého učence. [Jan Ev. Purkyně 1787-1937: Collection of Articles in Honor of 150th Anniversary of Birth of Czech Scientist.] Paper. Pp. 325, with illustrations. Prague: Purkyně Society for Study of Life and Works of J. E. Purkyně, 1937.

This book consists of twenty-seven essays on the life and work of Johannes Evangelista Purkinje. Among the contributors are the foremost Czech scientists. The volume is divided into two parts: In the first are discussed Purkinje's contributions to science; in the second, some phases of his private life, his character, his philosophy, his love of literature and his efforts to awaken the national spirit of the Slavs in general and of the Czechs in particular. The last seventeen pages contain a list of Purkinje's publications and a program of the international celebration in Prague in September 1937 to commemorate the one hundred and fiftieth anniversary of his birth. It is claimed that Purkinje is the founder of microscopic anatomy and experimental physiology in Germany. His noteworthy contributions to the biologic and medical sciences make him one of the founders of modern medicine. Among his contributions to biology was his description of the cell, which he considered the fundamental unit of the living organism. He was the first to use the term "protoplasma" to designate the living substance of a cell, and the second after Dujardin to call attention to the existence of this substance. He is credited as being the first anatomist to describe the nerve cells in the brain, spinal cord and ganglions as well as the first to demonstrate glandular tissue in the stomach. He made many original studies on the eye, heart, sex organs, skin, blood vessels, connective tissue, cartilage and bone. With the acquisition of the Plössl microscope later in his life he was able to amplify these studies. The account of his pharmacologic experiments makes interesting reading. Many of these studies he carried out on his own person. He investigated the action of camphor, digitalis, belladonna, opium, ipecac, turpentine and other substances. He systematized dactyloscopy, classifying finger prints into nine groups. A modification of this classification is being used now in criminology. About the importance of physiology in medicine he wrote:

> A modern physician cannot be trained for research or physiology by attending the clinics or by the study of the old masters. His training, beginning with the observation on the sick, must continue in the laboratory, where science is taught and where progress in contemporary medicine is made. It is clear then that physiology, in whose domain rests this experimental laboratory investigation, is the climax of the education of a modern physician, the crown of his medical understanding and the embryo of further progress. For a physician must not be deceived about understanding disease when he can designate it by name or place it into a certain system; he must take to mind that only then does he understand disease when he masters it scientifically, prognostically as well as therapeutically. The attainment of this progress is possible only through physiologic investigation. It is evident, therefore, that physiology is the fundamental medical science.

Purkinje's extreme modesty prevented him from publishing many interesting and valuable observations. The Purkinje Society of Czechoslovakia is engaged in bringing to light such material as has not been presented thus far, as well as in solving some of the controversies regarding priorities. This stimulating book is highly recommended to research workers and physicians. It is unfortunately not available in English translation.

Physiologie des Nebennierenmarkes. Von Gustav Bayer und Doz. Dr. Dr. Theodor Frhr. v. d. Wense. Band VI, Zwanglose Abhandlungen aus dem Gebiete der Inneren Sekretion. Herausgegeben von Professor Dr. W. Berblinger. Paper. Price, 11.70 marks. Pp. 87. Leipzig: Johann Ambrosius Barth, 1938.

More than one fourth of this comprehensive but not analytic and critical review of the literature on the adrenal medulla, epinephrine and "sympathin" during the last twenty-five years is taken up by the bibliography. The brief citations of the numerous inconclusive, if not contradictory, results of research, without much attempt at appraisal, especially in the section dealing with the possible relation of the adrenal medulla to the other endocrines, leaves most doctors not much wiser.

Modern Anæsthetic Practice. Edited by Sir Humphry Rolleston, Bt., G.C.V.O., M.D., and Alan A. Moncrieff, M.D., F.R.C.P. Published on behalf of The Practitioner. Cloth. Price, 10s. 6d. Pp. 231, with 6 illustrations. London: Eyre & Spottiswoode (Publishers) Ltd., 1938.

This volume is prepared especially for the general practitioner of medicine in England. The introduction by Blomfield and the first chapter, by Hewer, on theoretical aspects of anesthesia and analgesia, are the best portions of the book and are appropriate for any textbook on anesthesia. Chapter 2, by Featherstone, on the use of volatile anesthetic agents, is conservative and to the point although nothing new is presented. Chapter 3, by Macintosh and Pratt, on nitrous oxide anesthesia in surgery, does not seem to belong in a book bearing the title of Modern Anaesthetic Practice, except for the discussion of the use of nitrous oxide in minor surgery and the value of preliminary medication in connection with its use. Chapter 4, by Ashworth, on basal anesthesia, presents briefly the common practice in England with basal anesthetic agents. Chapter 5, on endotracheal anesthesia, summarizes briefly and well the endotracheal method of anesthesia. In chapter 6, on spinal anesthesia, the present trend in spinal anesthesia is presented conservatively without going into much detail. Chapter 7, on anesthesia and analgesia in midwifery, is excellent and represents a conservative view on the relief of pain in childbirth. Chapter 8, by Evans, on anesthesia and the child, is commendable and deserves to be read by anesthetists in general. In chapter 9, by Vaile, on anesthesia in dentistry, is presented the English attitude in anesthetizing the dental patient but nothing new is presented. Chapter 10, by Romanis, on local anesthesia and analgesia, is conservative but excellent as far as it goes; few types of block anesthesia are discussed, however; the main thing stressed is the value of infiltration with procaine and epinephrine, which is not debatable. Chap-

ter 11, by Magill, on the anesthetic aspects of postoperative care, is one of the most valuable chapters in the book and could be read to advantage by all anesthetists and surgeons. Chapter 12, on risks of explosion in anesthesia, is an excellent summary of present day opinion on the subject. This is a book that most anesthetists of this country will want to read at least, if not own. Its value for general practitioners in the United States is not apparent.

Dunant: The Story of the Red Cross. By Martin Gumpert. Cloth. Price, $2.50. Pp. 323, with portrait. New York: Oxford University Press, 1938.

This book is the pathetic, not to say tragic, story of the Nobel peace prize winner Henri Dunant, who was the first to entertain the conception of an international society for the alleviation of the sufferings of wounded in battle and of prisoners. Dunant was an ordinary citizen of Geneva, somewhat better off than the average, if not actually wealthy, who was engaged in the banking business. He came into contact with war somewhat accidentally at the battle of Solferino, where the French and the Austrians met in 1859. Here he was plunged into the midst of the fighting and saw the miserable lack of accommodations for the wounded and the total absence of doctors, nurses and medical supplies. He plunged into the emergency and made heroic efforts to supply as much as possible of the need through his own labor. Needless to say his success was scarcely worth mentioning, but the impression of horror was etched so deep on his mind that it dominated the rest of his life. After Solferino he could never get rid of the idea and he traveled all over Europe meeting statesmen, kings, emperors, politicians, society leaders and literati. He became a salesman for an obsession. Quiet and retiring in nature, he was relentless in a gentle sort of way and had an exceedingly persuasive way with persons whom he could meet individually. He was in no sense a rabble rouser; neither was he an organizer. In fact, though the Red Cross idea was his, the development of the idea was made possible largely through the organizing ability of one of his associates, Moynier. Toward the end of his life Dunant was disappointed by the hypocrisy and lip service of many who professed adherence to his idea and this, coupled with bankruptcy from squandering his resources on the promotion of his ideas, caused him to retire into oblivion, from which he did not emerge until he was accidentally discovered living in obscurity in Switzerland. He then received the Nobel peace prize, which he dedicated in its entirety to furtherance of Red Cross work, for by this time the International Red Cross had been established and was to a large extent functioning. The book is written with what is obviously an intense affection for Dunant. His tragic life story is depicted with sympathetic understanding and an appreciation of the mental and spiritual struggle which motivated the founder of the Red Cross. The author also develops and strongly emphasizes the idea that the Red Cross in its present form and functioning is a negation and a betrayal of the ideals and purposes of the founder, who is represented as coming in his later years to a feeling that his first proposal for aid on the battlefield was a totally inadequate approach and that the real function and purpose of the Red Cross should be to agitate for universal peace. Whether one takes the view of the author or not, the fact remains that the Red Cross as we know it is a living monument to the tragic life of Henri Dunant.

Classic Descriptions of Disease With Biographical Sketches of the Authors. By Ralph H. Major, M.D., Professor of Medicine, University of Kansas School of Medicine, Kansas City. Second edition. Cloth. Price, $5.50. Pp. 727, with 137 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1939.

Distinctive in this edition are sections covering malaria and yellow fever as well as many new illustrations. The author points out that many of the biographic sketches have been rewritten, and the index has been revised and enlarged. For the student and the teacher of medical history as well as for the dilettante in this field Major's contribution is invaluable. Even for those who have been little concerned in the past with medical history the book will be attractive and will serve in many instances to initiate them to a lifelong interest in this field.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Foot Drop Following Operation on the Knee; Res Ipsa Loquitur.—The plaintiff sued the defendant physicians to recover damages for injuries allegedly due to their negligence in performing an operation on his left knee. The trial court directed a verdict for defendant Carlson and entered an order of non-suit in favor of the defendant Ream. The plaintiff then appealed to the district court of appeal, first district, division 2, California.

The plaintiff suffered a strain of the crucial ligaments and external lateral ligaments of his left knee and was treated by defendant Carlson. As a result of the treatment, the plaintiff was able to walk and had full use of his left leg and foot but some instability remained in his left knee which made it impossible for him to perform the work he had formerly been employed to do. To correct this condition, defendant Carlson, assisted by defendant Ream, operated on the knee. Immediately thereafter the plaintiff suffered from foot drop and his leg was placed in a cast, but the treatment resulted in no improvement. About five months later a third physician performed an operation on the knee and found that the external peroneal nerve had been severed at a point approximately where its course intersected the course of the incision made by defendant Carlson. The ends of the nerve were freshened and sutured together, but there was practically no improvement in the plaintiff's condition.

It was conceded that the nerve was severed during the course of the operation performed by the defendants. On appeal, the plaintiff contended that the defendants failed to examine the nerve before closing the wound to ascertain whether it had been injured and that this omission constituted negligence. This contention, the court said, was without merit. The medical testimony disclosed that the nerve was not laid bare but was retracted with the tissue surrounding it. To examine it, the surrounding tissue would have had to be laid open along the length of the nerve, an act which might itself have resulted in severe injury to the nerve. The evidence further disclosed that the standard practice of surgeons of good repute in the locality was to ascertain after the completion of the operation and after the patient had regained consciousness whether the nerve had been injured by means of testing certain reflexes in the lower leg and foot. This was done in the present case, the court pointed out.

The plaintiff next contended that the doctrine of res ipsa loquitur applied and therefore an inference of negligence might arise sufficient to support a verdict in his favor. The determining factor, the court said, as to whether the doctrine applies in operative cases of the kind under consideration is whether the act causing the injury is one which can be visualized by the layman or whether it is one which depends entirely on scientific or medical knowledge. The plaintiff was completely anesthetized when the operation was performed on his knee and it was impossible for him to know what occurred. The defendants were in complete charge of the operation during the course of which the external peroneal nerve was severed. The nerve was not being treated and it was not in any way diseased. While the nerve lay in the operative field, it was involved only to the extent that it had to be retracted to one side in order that the operator might go beneath it. Scientific or expert opinion was not required, in the opinion of the court, because no question was raised with respect to negligence either in the diagnosis or treatment of a human ailment. The testimony of experts was necessary to establish the facts concerning the location and function of the external peroneal nerve, the location of the crucial and external lateral ligaments of the left knee, the location of the operative fields, and the extent to which the external peroneal nerve was involved in the operation which the defendants undertook to perform. But, once these facts were established, the inference of negligence was one which may be drawn by the application of the common knowledge of laymen.

The doctrine of res ipsa loquitur, where applicable, gives rise to an inference of negligence. If that inference is met by the

introduction of evidence which rebuts it, then the inference is overcome and a non-suit or directed verdict is proper. The evidence introduced by the defendant Carlson, the court pointed out, made no attempt to explain how the nerve was severed. Three expert witnesses for the defendants testified that the methods followed by the defendants in the course of the operation constituted good standard practice, as followed by surgeons of good repute in the same locality. But no one testified that the actual operation as performed was done with due care in all its details. These witnesses testified also that even though the operation on the knee were performed with due care, the external peroneal nerve would be severed in from 5 to 9 per cent of the cases and that the presence of scar tissue caused by the injury to the ligaments would increase the likelihood that the nerve would be severed. None of this evidence, the court said, rebutted the inference of negligence with respect to defendant Carlson in a clear and positive manner and the trial court should not have directed a verdict in his favor.

As to defendant Ream, the record presented a different case, in the opinion of the court. The plaintiff contended and the defendants conceded that the nerve was severed during the course of the operation. The evidence was clear, positive and uncontradicted that defendant Ream had not cut around the peroneal nerve. He handled the retractors after they were placed by defendant Carlson, who testified that defendant Ream handled no instruments that would actually have severed the nerve. In the light of this evidence, the inference of negligence which might arise from the application of the doctrine of res ipsa loquitur was completely rebutted and dispelled as to defendant Ream by clear, positive and uncontradicted evidence. It followed, the court said, that, as the inference of negligence as to this defendant was dispelled from the case as a matter of law, the order granting a non-suit was proper.

The appellate court, therefore, affirmed the order granting a non-suit in favor of defendant Ream but reversed the judgment entered on the directed verdict in favor of defendant Carlson — *Engelking v Carlson (Calif.), 80 P. (2d) 96.*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Ophthalmology, St. Louis

22: 1-118 (Jan.) 1939

Facial Hemiatrophy: Report of Two Cases. F. B. Walsh, Baltimore.—p. 1.

Staphylococcus Toxin: Experimental Study in Rabbits. J. H. Allen and A. E. Braley, Iowa City.—p. 11.

Influence of the Central Nervous System on the Pigment Migration in the Retina of the Frog. H. M. Burian, Hanover, N. H.—p. 16.

A Contact Lens-Telescopic System. J. W. Bettman and G. S. McNair, San Francisco.—p. 27.

*Vitamin Therapy in Ophthalmic Practice. J. Laval, New York.—p. 33.

Lectures on Motor Anomalies: V. Development and Course of Strabismus. A. Bielschowsky, Hanover, N. H.—p. 38.

Parallel Study of the Pathogenesis of Rhinogenous Optic Neuritis and of Serous Iritis. B. Waldmann, Oradea, Rumania.—p. 44.

Intra-Ocular Tension in Electropyrexia: Preliminary Report. H. C. Ernsting, Cleveland.—p. 54.

Causes of Blindness in Indiana. D. H. Row and C. D. Chadwick, Indianapolis.—p. 57.

Vitamin Therapy in Ophthalmic Practice.—Laval suggests that in certain ophthalmologic conditions in which deficiencies of vitamins exist it might be theoretically valuable to prescribe the following treatment: 1. A tablespoonful of cod liver oil twice daily should be prescribed in cases of poor dark adaptation, phlyctenular keratoconjunctivitis, photophobia and low grade conjunctivitis in women who are on a slenderizing diet or in cases of other corneal and conjunctival lesions in which the history shows a deficiency of vitamin A. 2. In cases of incipient cataract, optic neuritis, retrobulbar neuritis and also toxic amblyopia vitamin B (B_1 and B_2) may be prescribed. This could be taken daily in the form of eight tablets of brewers' yeast or in the powdered form. 3. The juice of at least two large oranges or one grapefruit daily can be ordered in cases of incipient cataract. (This is plus the brewers' yeast, which is also to be taken daily.) In cases of intraocular hemorrhage the juice of four lemons daily is suggested.

American Journal of Orthopsychiatry, Menasha, Wis.

9: 1-272 (Jan.) 1939. Partial Index

Enuresis: Study in Etiology. Margaret W. Gerard, Chicago.—p. 48.

*Incidence of Enuresis and Age of Cessation in 1,000 Neuropsychiatric Patients: Discussion of Relationship Between Enuresis and Delinquency. J. J. Michaels, Boston, and Sylvia E. Goodman, Ann Arbor, Mich.—p. 59.

Enuresis in Neuropsychiatric Patients.—According to Michaels and Goodman, there was an incidence of 19.3 per cent of enuresis in 1,000 neuropsychiatric patients distributed in fourteen diagnostic groups. The incidence was significantly higher in the groups of psychopathic personality (32.2 per cent), psychiatric behavior problems (43.8 per cent) and mental deficiency (33.3 per cent). There were consistently more males among the enuretic, this being especially prominent among the psychopathic personalities and the psychiatric behavior problems. Patients with manic depressive psychosis presented the lowest incidence of enuresis (12.4 per cent) as well as the smallest percentage of males among those who had enuresis. Persistence of enuresis was encountered in 35.7 per cent of the group with behavior problems. The triad association of male, psychopathic personality and enuresis seems worthy of serious consideration. Enuresis in its stubborn persistence reflects psychosomatically the lack of an internal inhibitory agent just as delinquency later reflects this lack sociopsychologically. Persistent enuresis is the prototype of the expression of deficient inhibitory tendencies, a weak ego and a reflection of an ill balance of the types belonging to the psychopathic personality, the delinquent and the psychiatric behavior problem. Its roots are embedded in the instinctual layer of the personality. It indicates faulty integration in the component levels of the personality and a lack of maturation. If enuresis is such a prophetic indicator of psychobiologic reactivity, the need for more intensive study of enuresis in the individual person is self apparent.

Thiamin Chloride for Tabetic Pains.—Metildi used thiamin chloride in the treatment of lightning pains of six tabetic patients in whom the tabes dorsalis process was not actively progressive. In each of these cases antisyphilitic treatment by standard methods had been ineffectual in relieving lightning pains. Thiamin chloride was given intramuscularly or intravenously. The patients were relieved of these pains either completely or in part in a few days after the injection of 10 mg. of thiamin chloride. The injections are being continued at weekly intervals. The period of observation is as yet too short to permit evaluation of the results.

Reinfection in Neurosyphilis.—Kopp and Solomon present a case of probable reinfection with syphilis in a patient who had neurosyphilis. The patient was continuously under observation in one clinic for eleven years. Numerous negative blood and spinal fluid examinations were obtained during this period. It is possible that reinfection occurred in this patient, who had developed early asymptomatic neurosyphilis while under active treatment for his first infection. Multiple chancres developed during the second infection.

Hereditary Ectodermal Dysplasia.—Clouston has made some additional observations on the hydrotic types of hereditary ectodermal dysplasia. He presents a chart showing that its severity is decreasing. The first four cases of the anhydrotic type of ectodermal dysplasia to be reported in Canada are cited with biopsy records and the third postmortem study is given. The condition is much more common than is usually believed. The distinctive marks are diminished sweating, dental aplasia and a rhinitis which has usually been called "atrophic." This is shown to be hypoplastic; the mucous glands of the nose and throat are diminished in number or absent. The resultant lack of defense and aeration, combined with loss of emergency temperature control, is probably a heretofore unrecognized cause of death in infancy. Recognition is not made because death occurs before the children are old enough to complain of the heat and before the distinctive dentition has occurred. Breast tissue was shown to be absent by the microscope. The question is raised as to what extent ozena is a hereditary ectodermal defect. It did respond to estrogenic substances. Evidence is given that the endocrine glands of ectodermal origin are involved in the general ectodermal dysplasia.

Estrogen Intranasally in Constitutional Deafness.—Mortimer and his colleagues report the results of the insufflation of estrogen intranasally in a series of fifty-five cases of constitutional deafness. Of the patients treated between July 1936 and September 1938 there are thirty-nine females and sixteen males. The cases were mostly diagnosed as either "otosclerosis" or "nerve deafness"; no attempt was made to select any given type of case. The patients range in age from the second to the sixth decade of life. Treatment consisted of daily nasal insufflation of 1 cc. of oil containing 1,000 international units of estrogen. None of the patients were treated for less than three months. Many of them have been under treatment for six months and there are some who have been treated intermittently for two years. As controls, eight males and six females have been observed. Before and during the treatment, at intervals of from one to two months, the hearing acuity in each ear of each patient was measured. Statistical examination shows that when all the data for 512, 1,024, 2,048 and 4,096 cycles are considered, the hearing of the treated males improves slightly while that of the untreated males deteriorates slightly. At these same frequencies the hearing of the treated females also improves slightly and of the untreated ones it appears to deteriorate. The high incidence of cranial dysplasia in 153 cases of constitutional deafness is discussed. The authors draw attention to the distribution of cranial types in this group and its similarity to the type of distribution in atrophic rhinitis and ozena. They suggest that these two constitutional diseases may have a similar or even share a common constitutional background. This view, they believe, finds additional support in that the two constitutional defects coexist in the same individual and in the same familial stock more often than it is generally recognized (in such stock the two defects may be distributed through one generation or in successive generations) and in that treatment which acts specifically on the nasal disease is capable of producing not only marked improvement in certain individual cases of the aural defect but also a statistically significant amelioration in the hearing level of the constitutionally deaf. The authors do not imply that constitutional deafness is an endocrine disease.

Mental Retardation with Congenital Heart Disease.—Ross points out that in the Harriet Lane Home those working in the cardiac clinic observed that many of the children with congenital cardiac lesions were often placed in special classes because of difficulty in school work. This observation led to a study of the incidence of mental retardation in patients with congenital heart disease. The cases studied were limited according to age (not more than 14 years) by the admitting rules of the Harriet Lane Home Dispensary and, in order to have a reasonable expectation of accurate results by the Binet-Simon intelligence tests, no child less than 5 years of age was included. Eleven boys and eleven girls ranging from 5 to 14 years of age were observed. Fifteen of these had been followed in the cardiac clinic, but the diagnosis was well checked in all. In these cases, patent interventricular septum (eight) and patent ductus arteriosus (six) were most common. The diagnosis was patent interauricular septum in four, pulmonary stenosis in two and valvular disease in one, and the pathologic condition was undetermined in one. None of the subjects fell in the idiot class but two had intelligence quotients below 50, seven fell in the moron group and eight were in the dull normal group. Only four were within the normal range of 91 to 110, and the highest of the group had an intelligence quotient of 117. There was no relation to the type of lesion, as the diagnosis in the two lowest and the one highest in the whole group was patent interventricular septum. This group was compared with a cross section of the Harriet Lane Psychiatric Dispensary patients, 1,000 cases. This group was felt to be fairly representative of the general outpatient population. The dull normal range was the same in all categories, but among those with congenital cardiac lesions the

moron group was much larger and the normal group much smaller than in the outpatient population The study appears to show that the intellectual endowment, as measured by the Binet-Simon intelligence tests, tends to be somewhat lower in the group suffering from congenital heart disease

Pertussis Prophylaxis.—Singer-Brooks presents the results of pertussis prophylaxis obtained over a period of three years during which ninety-five children were injected with undenatured bacterial antigen, 272 children with phase I Haemophilus pertussis vaccine and 256 children were not protected and served as controls for treated groups Of the ninety-five children injected with undenatured bacterial antigen thirty-four were exposed and in twenty-eight of these pertussis developed, making the attack rate 29 4 per cent Of the children injected with phase I Haemophilus pertussis vaccine, forty-two were exposed to pertussis Haemophilus pertussis infections developed in seven of these The attack rate in this group was 2 5 per cent Seventy-one of the control children were exposed to pertussis and in sixty-two of these attacks developed The attack rate in the 256 control children was 24 2 per cent The treated children have not been observed over a sufficiently long period to determine conclusively the duration of the protection conferred

Anemia of Rheumatic Fever.—Hubbard and McKee observed the changes in the blood of seventeen patients with nineteen characteristic recrudescences of rheumatic fever All had well established rheumatic fever with cardiac complications Their ages ranged from 5 to 16 years None received any drugs which could be considered to have any bearing on the production of anemia The patients were treated with the usual supportive measures including salicylates, diuretics and digitalis Six of the exacerbations progressed to a fatal termination All other patients were followed during their convalescence until the activity subsided It was found that in association with the active phases of rheumatic disease a secondary anemia develops which is often quite severe As the infection subsides, the blood levels tend to return to normal Therefore the presence of anemia may often be an indication of continued rheumatic fever activity

Incidence of Syphilis in Army.—Blount points out that the Kline diagnostic and exclusion tests were performed on the serums of 5,000 army recruits and soldiers having previous service All serums giving positive reactions were checked by the Wassermann and Kahn reactions Sixty one cases (1 2 per cent) of syphilis were found The incidence varied from 0 52 per cent in recruits from 18 to 23 years of age to 5 5 per cent in those from 30 to 35 years old In soldiers having previous service the incidence varied from 1 per cent in those from 20 to 23 years old to 18 1 per cent in those from 42 to 59 years of age However, few men between the ages of 42 and 59 years were examined Soldiers with tropical service had a slightly higher incidence of syphilis than did those with service only within the continental borders of the United States More than 50 per cent of the cases of syphilis found were so-called latent, but a relatively large number of cases of cardiovascular and cerebrospinal syphilis were found The author believes that the examination of all recruits, as well as periodic surveys of the personnel of the army, would be of value to it

Polyneuritis in Children.—Cutts states that the incidence of polyneuritis among the children of Minnesota is low but that the prolonged and severe disability requiring nursing care, physical therapy and, in some cases, orthopedic surgery make the condition an important one The gross pathologic changes of polyneuritis are usually minimal although some swelling and congestion of the peripheral nerves may be detected The symptoms of polyneuritis are usually both sensory and motor Customarily the lower extremities are first involved, with progression to the upper extremities and trunk The distribution is roughly symmetrical General treatment during the active stage consists of supportive measures, elimination of foci and sources of toxin, improvement of nutrition, protection of the weakened muscles and the use of oxygen when the muscles of respiration are involved As recovery progresses, physical therapy and orthopedic appliances are usually indicated Surgery may be required to decrease disability when recovery has been incomplete Specific measures are indicated when a specific cause can be determined Metallic poisoning, either accidental or as a result of therapy, accounts for a considerable proportion of these cases Of the metals the most frequent offender is lead Lead may be ingested by children as a result of chewing paint from furniture and toys Food and water may become contaminated from pipes or containers Insecticides and sprays are other possible sources The prognosis for complete recovery after lead polyneuritis is not as good as after most types because involvement of the spinal cord is generally greater In the cases presenting evidence of lead encephalitis the prognosis is considerably worse Arsenic, thallium and bismuth are other metals capable of producing polyneuritis Cases of polyneuritis due to or associated with infections are less readily classified That following diphtheria is considered the most common type in children Diphtheritic polyneuritis is almost invariably preceded several days by local paralysis such as the paralysis of the soft palate and pharynx associated with faucial diphtheria Neuritis occurs almost exclusively in cases in which antitoxin has been administered late or in inadequate dosage A small group of cases has been reported in which neuritis developed several days after a brief febrile illness of undetermined origin The polyneuritis in these cases is roughly symmetrical, usually associated with bilateral facial paralysis, frequently affecting proximal muscle groups of the extremities more than the distal groups If the acute stage is survived, recovery is usually rapid and complete Periarteritis nodosum is said to be accompanied by polyneuritis in 20 per cent of the cases It occurs rarely and the neuritic symptoms are likely to be overshadowed by the other symptoms of the disease Polyneuritis occasionally complicates other diseases tuberculosis, typhoid, paratyphoid, malaria, septicemia, pyogenic infections, scarlet fever and mumps Diabetes in children is rarely complicated by polyneuritis Several drugs other than the metals mentioned have been cited as causes of polyneuritis Among these are dinitrophenol, atabrine, sedatives of the chloral group and, rarely, anesthetics, including ether and

procaine hydrochloride. Occasional cases have been reported following the administration of foreign protein such as therapeutic serums. Hematoporphyrinuria and hematoporphyrin hydrochloride used therapeutically may also cause polyneuritis. Dietary deficiencies are known to be capable of causing neuritis. Until recently, massive doses and parenteral administration of vitamin B have not been practicable. Since vitamin B_1 is now available in pure concentrated form, information should soon be available concerning its use in the less common types of polyneuritis. Whether large doses of vitamin B_1 orally or parenterally will have any beneficial effects in the treatment of polyneuritis following diphtheria and the metallic and drug intoxications remains to be determined.

Serum Volume Test for Hemorrhagic Diathesis.—Boyce and McFetridge discuss the underlying causes of the hemorrhagic diathesis in jaundice with special reference to Quick's prothrombin theory. The procedure for carrying out their serum volume test for the diagnosis of the hemorrhagic diathesis in jaundice is given in an abstract in THE JOURNAL Jan. 8, 1938, page 158. Twenty-one cases of jaundice are reported, all of which were studied by the serum volume test, the Ivy venous pressure test and the Quick hippuric acid test of hepatic function. The serum volume test proved correct in all cases, but the Ivy test did not. Since the serum volume test and the Quick hippuric acid test failed to correspond frequently, the authors ask whether depressed hepatic function can be invoked to explain all cases of bleeding in jaundice. They outline the preparation of jaundiced patients for surgery, referring especially to the use of blood transfusion, dextrose and vitamin K.

Testosterone Propionate in Prostatic Hypertrophy.—Recently Bolend reported the results obtained with the use of testosterone propionate in twenty-three unselected cases of enlarged prostate with urinary retention. Ten patients are clinically well or symptom free, seven patients are improved and six experienced no improvement. Critical examination of the clinical data shows that, while ten patients are clinically well and symptom free, some of them carry from 5 to 35 cc. of residual urine. The patient giving the most striking clinical response has 130 cc. of residual urine. These patients, however, all consider themselves cured. In a later series of thirty-five patients the clinical course corresponds to the foregoing except that there was a higher percentage of beneficial results, owing to the fact that only patients with uncomplicated benign hypertrophy were treated. It has not been possible to demonstrate conclusively by palpation or by cystograms that the prostate is actually reduced in size. Hence, in his effort to determine how and why these patients are able to empty their bladders more completely, the author studied sections from the prostate of seven patients treated with varying amounts of the drug. Careful and accurate clinical data with biopsies before and after treatment were kept. Three changes were observed in the gland following treatment: (1) an exaggeration of glandular hyperplasia, (2) a reduction or at least no increase in the stroma and (3) a reduction in the inflammatory reaction. If there is any change in the individual epithelial cells, the change was not constant enough to be significant in the cases studied.

Chorea and Athetosis in Childhood. J. Shafar.—p. 259.
Exophthalmic Goiter in Children. F. R. B. Atkinson.—p. 267.

Cause of Paralysis in Diphtheria.—Taylor discusses some of the evidence bearing on the manner in which diphtheria toxin attacks the nervous system. The view held by some authors is that all forms of diphtheritic paralysis are due to hematogenous toxemia, the frequency with which certain nerves are attacked being explained by the selective affinity of the toxin for these nerves. The close anatomic relationship between the site of infection and the initial paralysis has led other observers to discard this theory in favor of extreme views of a different nature. They state that the toxin first attacks the nerves in the locality of the site of infection and that all other paralyses are produced by diffusion of toxin in the nervous system from the point of entry. This view receives some support from the orderly sequence of paralyses commonly noted in faucial diphtheria. The two schools of thought meet in the theories advanced by Walshe that (1) the initial paralysis is caused by lymphogenous invasion of the nervous system, the toxin passing from the site of infection to the central nervous system by the perineural lymphatics, (2) generalized paralysis is the result of hematogenous toxemia and (3) accommodation paralysis is the result of the selective affinity of circulating toxin for certain elements of the nervous system. Most clinicians and experimental workers are agreed that the late multiple neuritis following diphtheria, giving rise to diphtheritic pseudotabes, is due to hematogenous toxemia. The strongest evidence of the hematogenous origin of such paralyses is the fact that the experimental injection of diphtheria toxin intravenously in animals produces a multiple neuritis which is exactly comparable to this late form of peripheral neuritis found in diphtheria in the human being. In addition to the limb paralysis, accommodation paralysis must be included in the group of symptoms due to blood-borne toxin, because this form of paralysis is found quite frequently in both faucial and extrafaucial diphtheria. There are good grounds for believing that hematogenous toxemia is capable of producing, in addition to generalized paralysis, a type of paralysis similar to the local paralysis found in faucial diphtheria. The author believes that one may thus accept the possibility that blood-borne toxin may play some part in the production of local paralyses as they are encountered in faucial diphtheria. The close anatomic relation between the local paralysis and the site of infection can leave no doubt that the nervous system is primarily attacked by local absorption of toxin. Unilateral faucial diphtheria frequently results in paralysis of the corresponding side of the palate. An important and familiar clinical observation is what has been described as the "march of paralysis." One cannot but be impressed by the orderly way in which paralysis develops in most severe cases, palatal paralysis preceding pharyngeal and the diaphragm being involved before the intercostal spaces. Such a march suggests the slow spread of toxin in the central nervous system.

Bazin's Disease. J. Kinnear.—p. 18.
Two Families Showing Hereditary Ectodermal Dystrophies. C. Hardwick.—p. 24.

Etiology of Seborrheic Dermatitis.—Dowling states that the cause of seborrheic eczema is not established but that the available evidence points to a primary infection with yeastlike organisms, usually saprophytic but capable of developing varying degrees of pathogenicity under different conditions. Why some cases are fixed and stationary while others are acute is not always easy to explain, but there can be little doubt that these variations depend on a number of factors. Seborrheic eczema in its pure form often undergoes alteration owing to pyococcic invasion or to numerous local and constitutional factors. These secondary changes may so alter the clinical picture that the diagnosis of the original dermatosis may be a matter of guesswork. One has to depend largely on the presence of a certain number of typical lesions, the characteristics of which Darier has described.

Etiology of Seborrheic Dermatitis.—Percival separates seborrheic dermatitis into three groups: (1) pityriasis capitis and eczematide lesions affecting the hairy or potentially hairy regions, (2) flexural dermatitis, which is almost always exudative, and (3) pustular dermatitis affecting areas covered with strong hair. He summarizes the evidence which has a bearing on the etiology of cases labeled "seborrheic dermatitis" into the following: 1. An almost specific type of organismal infection is associated with each case group and clinical observation of the course of the eruptions and their response to treatment suggests, even in the absence of scientific corroboration, that infection plays a definite part in their production. 2. In all three case groups a type of eczematous reaction, which is distinct for each group and which is different from the eczematous reaction produced by chemical irritation, is a characteristic and diagnostic feature of the eruption. 3. The clinical features, bacteriologic findings and response to treatment in the three groups of cases are so distinctive that each group stands out clearly as an individual clinical entity. In the absence of definite proof the author suggests that an external infective origin should be presumed temporarily for all three groups. Furthermore, the same presumption might be extended to include infectious eczematoid dermatitis, and in descriptive nomenclature this group might be placed in the same class.

Cobra Venom in Nerve Leprosy.—The nerves most frequently involved in leprosy are the ulnar, peroneal, posterior tibial and median. These nerves were thickened and painful in nearly all the cases that Chowhan and Chopra observed. Injections of cobra venom relieved the severe nerve pains due to lepra reaction. In some cases injections were given locally to relieve pain of a particular part of the body, which was interfering with the sleep of the patient. It had been suggested that relief of nerve pain and other nerve symptoms in leprosy, after cobra venom, is due to its choline esterase-like action. In persons suffering from severe and constant nerve pains, there is probably an excess of acetylcholine in tissues produced by pathologic overstimulation of nerves and possibly the choline esterase normally present is insufficient to neutralize it. Since injections of cobra venom relieved nerve symptoms it is possible that it acted by neutralizing the excess of acetylcholine present. It is also possible that cobra venom may itself act like choline esterase or may have a substance of this nature present in it. The study of the biochemical changes in the blood of patients with leprosy before and after the injections of cobra venom is in progress, particularly its effects on choline esterase. It is not expected that cobra venom will ever replace chaulmoogra oil and other measures in the treatment of the nerve type of leprosy, but it may serve as an additional weapon in ameliorating some of the troublesome symptoms. From 60 to 70 per cent of cases of leprosy in India are of the

nerve type. Cobra venom has been shown to give marked relief in from 60 to 80 per cent of these cases, particularly if the injections are given into the macular and anesthetic patch. The sensations of numbness and formication are also improved. The relief of pain was observed after the second or third injection and the pain disappeared almost completely after the fifth or sixth injection. The criteria of improvement were the return of normal sensations and less disturbed sleep. Mixed injections of vitamin B_1 and cobra venom have resulted in definite benefit in a few cases of neuritis which did not improve with cobra venom alone. Vitamin B and cobra venom if used together would most probably be highly beneficial therapeutic agents in neuritic leprosy.

*Method of Giving Blood Transfusions to Infants. V. L. Collins.—p. 1121.

Blood Transfusions in Infants.—Collins describes a method of giving blood transfusions to infants which makes use of the malleolar vein. A needle with a stilet as a cannula, blood taking apparatus, rubber tubing with a lumen of 4 mm. and a record syringe with a three-way stopcock supply are the apparatus needed. The needle with a stilet renders the cannulizing of even a small vein a simple procedure. It is an ordinary large hypodermic needle (gage 18, 24 mm. in length by 1.2 mm. in thickness) shortened to 20 mm. The stilet projects 4 mm. beyond the end of the needle, which is cut straight across and beveled round its circumference so that it tapers to the stilet. One piece of rubber tubing, 25 cm. long, runs from the stopcock to the adapter, which fits the needle. A second piece of tubing, 30 cm. long, connects the stopcock to the vessel containing compatible citrated blood. The infant's foot is bandaged to a splint, the position of the malleolar vein is noted and under local anesthesia a transverse or oblique incision is made across the line of the vein just proximal to the medial malleolus. By placing a pair of Spencer-Wells forceps in the wound and opening them in a plane at right angles to the incision, the subcutaneous tissues can be opened as deep as the periosteum. When the periosteum is bared, the vein can be mobilized with an aneurysm needle, and two pieces of catgut passed beneath it in the customary manner. With fine scissors the vein is then cut half across, and the needle and stilet are introduced. The record syringe is attached to the stopcock and the rubber tubing is connected to the flask of blood. The tap is adjusted and blood is drawn into the syringe. Then the tap is turned on and any air in the syringe is expelled through the tube. As soon as blood is dropping from the adapter in this tubing, the stilet is removed and the adapter is fitted into the needle in the vein. The small amount of air in the needle can be ignored. The blood is then gently forced into the vein, and by refilling the syringe and adjusting the stopcock each time the desired amount of blood can be given. When the transfusion is completed, the pieces of catgut surrounding the vein should be removed and a dressing applied. A horsehair suture is rarely required for the incision. The amount of blood and the rate at which it is given depend on the circumstances. Usually it is desirable to take from twenty to thirty minutes to give 90 cc. of blood to an infant weighing 2.7 Kg. (6 pounds). In larger infants it is more satisfactory to transfuse blood by the continuous drip method, but this is not always possible when the veins are small. The author states that the method described has been found so satisfactory for intravenous therapy that it is now used throughout his hospital for all blood transfusions and the intravenous administration of saline solution. A slightly larger needle is used for continuous transfusion.

Sinucarotid Enervation: Technic, Indications, Results. L. Léger.—p. 176.
*Surgical Treatment of Diabetes. J. Bréhant.—p. 195.

Surgical Treatment of Diabetes.—Bréhant says that the attempts at surgical cure of diabetic conditions are only in their beginnings. The medical treatment looks only to substition for the deficient pancreatic function by the application of endocrine therapy; the surgical treatment aims to modify the relation between the two neurohumoral systems, which regulate the sugar metabolism and assure glycemic equilibrium. These two systems are: (1) the apparatus aiming at hypoglycemia, which consists of the pancreatic islands, the secretion of which is dependent on the pneumogastric nerve, and accessorily of certain endocrines such as the salivary glands and the parathyroids; (2) the apparatus acting in the hyperglycemic direction, which consists of the adrenal medulla, the secretion of which is dependent on the splanchnic nerves, and secondarily of certain endocrine glands such as the hypophysis and the thyroid. The surgical attempts that have been carried out thus far have aimed either at the strengthening of the vagopancreatic apparatus or its connected glands or at the depression of the adrenosplanchnic apparatus and its connected glands. The attempts at activation of the pancreatic function so far have given deceptive clinical results. Pancreatic transplantation is not feasible in human subjects. Sympathectomy of the arteries of the pancreas so far has only formed a part of the experimental sphere. Moreover, the attempts at transformation of the pancreas into a gland that is only endocrine, by alteration of the external function, have not given reliable clinical results. Among the attempts aiming to modify the endocrine status of the accessory glands, the only ones which rest on approved physiologic bases are the attempts of hormonal activation of the salivary glands or of the inhibition of the hypophysial apparatus. The first ones have not given appreciable clinical results; those of the second group were more encouraging, but the seriousness of hypophysectomy prevents the practiced application of a surgical intervention on this gland. There remain the attempts at the suppression of the adrenal apparatus. Rather than to attack directly the adrenal gland, the attempts thus far tend to rely to a certain extent on the operations of glandular enervation and in particular on splanchnicectomy. These attempts are sufficiently encouraging to be considered worthy of a trial in grave forms of diabetes that are resistant to insulin.

*Accidents of Skiing: Their Genesis, Frequency and Distribution. J. Braine and C. Goury.—p. 153.
Faciocervicothoracobrachial Neuralgic Syndrome Probably of Sympathetic Etiology. J.-A. Chavany.—p. 156.

Accidents of Skiing.—Braine and Goury point out that the technic of this sport has been specified and improved during recent years. Regarding the accidents that occur in the course of skiing, they say that in view of the large number of persons who do use skis the frequency of the accidents is relatively slight, other snow sports, such as tobogganing and bobsleighing, being much more dangerous. Statistics which are difficult to establish are deceptive; the seriousness of the accidents differs greatly and many of the minor lesions (small muscular and ligamentous ruptures and mild sprains), which constitute the majority of accidents, escape medical control. Accordingly, the authors cite figures with certain reservations. The incidence of skiing accidents is 0.5 per thousand. In the region of Freiburg, with more than 2,000 skiing students every Sunday during the winter, fourteen fractures and 160 sprains have been counted during one season. In the region of Innsbruck, 157 accidents, of which eighty-seven were fractures, have been counted in one year. After citing figures on the percentages of the serious, moderate and mild accidents, the authors give their attention to the etiology, pointing out that it depends on the equipment, the skiing terrain, the physical condition of the skier and the type of skiing. In estimating the equipment, the authors describe and illustrate the boots, the sticks and

their correct and incorrect attachment to the hand, and the different types of bindings, that is the devices by which the skis are attached, and so on. They also illustrate how the sticks may eventually cause dislocation of the shoulder. Discussing the role of the skiing terrain in accidents, they say that the frequency and the type of accidents, as well as the localization and the character of the traumatic lesion, are largely determined by the condition of the snow. Its quality varies according to the season. Especially dangerous is the snow at the beginning of the season and in the spring. Moreover, the consistency of the snow varies from day to day. Recently fallen snow may obscure obstacles. The physical condition of the skier and his training are also important factors in the etiology of accidents, for traumas are most frequent at the beginning of the season. That the type of skiing plays a part in the causation of accidents is proved by their high frequency in going down slopes and in mountain skiing. In skiing on level ground accidents are comparatively rare. In the last part of this report the authors give figures on the characteristic lesions that occur in skiing. The therapy of these lesions they intend to discuss in a later report.

*Neuromuscular Impairment of the Young of Rats with E Hypovitaminosis and Their Treatment with Synthetic Vitamin E. V. Demole and H. Pfaltz.—p. 123.
*Calcium and Training of Athletes. P. Martin.—p. 125.

Neuromuscular Impairment of Young of Rats with E Hypovitaminosis.—Demole and Pfaltz show that the young of rats with E hypovitaminosis frequently develop neuromuscular lesions during the period of lactation. Symptoms of these lesions are laziness, awkwardness, paresis, paralysis and convulsions. The administration of synthetic *dl*-alpha-tocopherol as well as of its acetyl ester during the first half of the period of lactation (up to fifteen days after birth) either to the mother animal or to the young prevents the appearance of these disturbances. If the tocopherols are administered during the second half of the period of lactation, existing mild disturbances such as awkwardness and pareses are cured but complete paralysis is not influenced.

Calcium and Training of Athletes.—Martin reports his studies on the influence of calcium therapy during the training of athletes. The young athletes who were the subjects of the experiments were mostly city dwellers who lived in modest circumstances and whose food was frequently deficient in calcium salts. Moreover, working in offices during the day, they had little opportunity to benefit from fresh air and sunshine. Before describing his experiments the author reviews some aspects of the physiologic and biologic role of calcium. Following this he cites several authors who employed calcium in treating athletes. His own experiments aimed to answer the question whether the administration of calcium permits the progressive intensification of training without producing the signs of excessive training. The tests were made on young runners (400 meters). Of a group of twenty-seven athletes, fifteen underwent training without calcium therapy; the other twelve were subjected to intensive calcium therapy during the five months of training (December to April). They were given daily two tablets of calcium gluconate or an equivalent amount of calcium in some other form. The author gives tabular reports of the results of the tests at the onset and at the end of the period of training. Recapitulating the results he says that the amelioration of the coefficient of fatigability (difference between the pulse rate on arrival after the 400 meter run and the normal pulse rate) was 60 per cent higher in the athletes who had received calcium than in those who had not received it. The improvement of the coefficient of rapidity of recuperation to the normal state (difference between the pulse rate ten minutes after finishing the run and the normal pulse rate) was 33.7 per cent better in the athletes who had received calcium therapy. The athletes tolerated the administration of calcium well. There were no complaints about difficulties in the absorption of the medicament. On the contrary, they felt the beneficial effect on their general condition.

Decline Posture in Therapy of Pulmonary Tuberculosis. D. D'Arcangelo and T. Todoroff.—p. 7.
*Influence of Parapneumothoracic Pleurisy on Contralateral Tuberculosis. N. Cavarozzi.—p. 21.

Parapneumothoracic Pleurisy in Contralateral Tuberculosis.—Cavarozzi's work was meant to determine whether parapneumothoracic pleurisy has an influence on the evolution of contralateral tuberculosis and what the mechanism of action of that influence is. The author followed the behavior of the contralateral lung before development and after recovery or improvement of typical, abundant and noncomplicated parapneumothoracic pleurisy in fifty-seven adults. Before development of pleurisy the contralateral lung was normal in eight cases. In the remaining forty-nine the structure showed clinical symptoms and x-ray changes varying from conditions of adenopathies or tuberculous infiltrations to different forms of tuberculosis. Collapse of the pneumothoracized lung was clinically efficient in ten cases, including those in which the contralateral lung was normal. After parapneumothoracic pleurisy the clinical symptoms and the roentgenograms of the contralateral lung were unchanged in twenty-five cases, including those in which the structure was previously normal. There was regression of tuberculosis in sixteen cases and aggravation of the disease in sixteen cases. The author found that behavior of the contralateral lung parallels that of the pneumothoracized structure in all cases unless the pleuritic fluid is infectious. In the presence of clean pleuritic fluid (either spontaneous or from thoracentesis and lavages) the contralateral lung does not change in most of the cases or it shows regression of tuberculosis. In these cases pleurisy follows a favorable evolution, and prompt recovery of the patients results. Aggravation of contralateral tuberculosis after parapneumothoracic pleurisy is observed in cases in which the pleuritic fluid is purulent or suppurative. However, the evolution of the condition is modified if the fluid is transformed from purulent to clean by proper treatment. According to the author, parapneumothoracic pleurisy has a mechanical action on collapse and a toxic and infectious action on the general system with a consequent indirect action on the contralateral lung. The nature of the action is biologic and infectious as the changes of collapse interfere with the control or stimulation of tuberculosis of the pneumothoracized lung, and the acute infectious nature of the fluid disturbs directly the general trophism.

Subarachnoidal Hemorrhage During Childhood. E. Engelhardt.—p. 436.

Susceptibility to Serum Disease.—By the statistical analysis of a large material, Beer aimed to detect fluctuations in the susceptibility to serum disease. He determined the incidence of serum disease in the cases in which treatment with diphtheria horse serum was administered during the twenty years from 1916 to 1935. He observed an increase in the percentage of serum disease during the spring months, more exactly during May and June compared to March and April. This increase he regards as the result of the general alteration in reactivity to which the organism is subject at this time of the year. There was no definite evidence of changes in the susceptibility in connection with the different ages of the patients; to be sure, the figures seemed to indicate with some probability that there was a greater susceptibility to serum disease during the first three or four years of life. However, this evidence was not sufficiently convincing to justify the drawing of conclusions. The author gave attention also to the articular complications of serum dis-

ease and observed an indisputable augmentation of their incidence corresponding to the increasing ages of the patients; moreover, he noted that the reactions on the part of the joints became manifest earlier in the older children and that the late articular complications (later than sixteen days after the injection) became rare in children over the age of 7 years. The author considers that these fluctuations in the type of articular involvement are the result of the progressive development of the joints.

Rheumatic Disease of the Heart.—Valvular lesions of the heart of nonsyphilitic origin, according to Etinger, are associated as a rule with rheumatic infection regardless of history of previous attacks of inflammatory disease of the joints. The etiologic identity of the so-called arthritic valvular lesions of the heart, as well as of those not associated with involvement of the joints, has been established by anatomic and clinical studies. The clinical diagnosis of rheumatic endocarditis is possible only on the demonstration of functional valvular derangement, which is possible during the acute period in relatively few cases. The question of the myocardial or endocardial origin of a systolic murmur heard in the apex in the acute stage of rheumatism has not been solved. The author stresses the point that regardless of the mechanism determining this murmur it does not necessarily point to a later development of the valvular lesion. In his experience not less than 50 per cent of such murmurs disappeared in a later course. Diagnosis of the involvement of the bicuspid valve is possible only after the lesion has been established some time after the attack. The recognition of the aortic lesion is not infrequently possible during the acute period on the basis of the diastolic murmur. Definite diagnosis of a mitral lesion is possible not earlier than one year after an attack of rheumatic arthritis. Its determining clinical syndrome is the appearance of a presystolic murmur, which indicates the beginning stenosis of the mitral opening. The progressing sclerosis of the involved valvular apparatus is conditioned not so much by the rheumatic flare-ups as by overwork and functional strain. The incidence of cardiac lesions in connection with recurrent attacks of joint inflammation is about the same as that associated with the first attack; thus rheumatic patients who have suffered one, two and more arthritic attacks are not guaranteed from developing valvular lesions in subsequent attacks. The absolute number of lesions arising in connection with recurrences is relatively small when compared with lesions arising in the prearthritic period or in connection with the first arthritic attack, which is explainable on the basis of diminishing frequency of recurrences with each attack as well as with diminution of the percentage of rheumatics with intact valvular apparatus with each consecutive joint attack. The author stresses the high incidence of valvular lesions in the prearthritic period. In his series of 420 patients entering the hospital in the course of the first involvement of the joints eighty-one, or 19.3 per cent, presented an old valvular lesion. Analysis of the author's material indicates a small percentage of involvement of the mitral valve alone (from 3 to 4 per cent) as well as a relatively rare incidence of isolated lesions of the aortic valves. The incidence of combined valvular lesions amounted to 40 per cent. This rate increases with each new flare-up of the joints. The author stresses the regular development of myocarditis in association with rheumatism as well as the fact that the recurring specific myocarditis frequently is the determining factor in the fate of rheumatic patients by provoking or increasing the cardiac insufficiency.

Position of Fetus in Uterus. D. G. Wesselink.—p. 252.

Tetany and Pregnancy.—According to Verhage, tetany is comparatively rare during pregnancy; at any rate this is the case if the atypical forms, without spontaneous convulsions, are disregarded. He reports two cases of tetany in pregnant women. In the first woman the tetany developed following a strumectomy that was performed eight days after the birth of the woman's third child. After this the woman became entirely well. She had no symptoms of tetany until she became pregnant. These symptoms subsided after the pregnancy was terminated but recurred again three years later when the woman became pregnant once more. The second woman developed tetany during pregnancy although she had not undergone an operation. However, the anamnesis disclosed that she had had symptoms of tetany ten years before, about six months before the menarche. In both cases the authors succeeded in counteracting the symptoms and in increasing the calcium content by means of parathyroid extract. However, normal calcium values were not reached before delivery. When after delivery the same therapy was continued, the calcium content increased further. In both instances the calcium content of the blood was considerably higher in the child than in the mother. However, when the calcium content of the maternal blood was extremely low, that of the blood of the child was likewise below normal. The anemia which accompanied the tetany yielded to treatment with reduced iron and, as the anemia improved, the calcium content of the blood increased. In a general discussion of the problem of tetany in pregnancy the author takes up the symptomatology, pathogenesis, prognosis and therapy. He shows that tetany must be regarded as a serious complication during pregnancy and during the puerperal period, although, thanks to the new forms of treatment (parathyroid extract and dihydrotachysterol), its prognosis has greatly improved in recent years.

Intestinal Paralysis in Extra-Abdominal Traumatic Injury.—According to Lehmann, traumatic injury involving the abdomen directly, especially with injury to intra-abdominal organs or hemorrhage, may produce intestinal paralysis. It is more difficult, however, to explain how extra-abdominal traumatic injury which is limited to the back, chest or pelvis can give rise to typical ileus. Some cases of serious paralytic ileus in traumatic injury to the back, including one with fatal outcome, gave rise to the studies here presented. In order to get some idea of the frequency of this traumatic form of ileus, the author investigated a material of 497 cases of extra-abdominal traumatic injuries limited to the region of the back, chest, pelvis and kidney. In this number eleven were found to be associated with more or less pronounced paralytic ileus. One case terminated in death. On the basis of the postmortem observations in this case, of the localization of the trauma in other cases and of experimental studies, the author suggests that the intestinal paralysis is due to an inhibiting action on the intestinal musculature. This effect is exerted by the sympathetic, which in turn is impaired by the formation of a hematoma. In eight of the eleven reported cases the hematoma was localized in the region of the splanchnic nerves, more especially on their intrathoracic course.

THE EFFECT OF RADIATION THERAPY ON GASTRIC SECRETION

WALTER LINCOLN PALMER, M.D.
AND
FREDERIC TEMPLETON, M.D.
CHICAGO

In this article we wish to describe certain effects of radiation therapy on gastric secretion in man. The studies were made on patients with peptic ulcer and with the therapy of ulcer in mind. This report, however, deals primarily with the effect on gastric secretion, because other methods of ulcer treatment were used in conjunction with x-rays and because a reliable appraisal of the therapeutic procedure is as yet premature.

Bruegel [1] in 1917 reported the production with radiation therapy of a temporary achlorhydria as measured by means of the usual test meals in vogue at that time. Bensaude [2] in 1925 described a decrease in acidity in six of eleven patients. Viviani [3] studied the effect of radiation on histamine secretion in 1931, reporting a definite depression, variable both in extent and in duration. Emery [4] in 1932 noted a temporary achlorhydria in four cases. The amount of therapy employed by these workers and the technic used varied greatly. Experimentally, Miescher [5] in 1923 found a moderate but temporary reduction in secretion in a dog after each of two courses of therapy. Portis and Ahrens [6] in 1924 produced complete achlorhydria in one dog with a Pavlov pouch and almost complete achlorhydria in another. Ivy, McCarthy and Orndoff [7] in 1924, Case and Boldyreff [8] in 1928, Snell and Bollman [9] in 1934 and Visscher [10] in 1937 described a variable and temporary reduction in gastric secretion in the dog following irradiation.

There is an increasing amount of evidence that acid gastric juice plays a most important role in both the pathogenesis and the healing of peptic ulcer or, to use Dragstedt's [11] term, "acid ulcer." No attempt will be made at this time to present the evidence for this point of view, but it is of interest in this connection to note that Miescher [5] twice observed the healing of a cutaneous ulcer adjacent to the stoma of a Pavlov pouch when the secretion from the pouch decreased as the result of irradiation. The great problem of therapy seems to be that of achieving more complete, more constant and more permanent neutralization or inhibition of the acid secretion. The excessive, continued night secretion appears to play an especially important role in the failure of ulcers to heal. Any method of depressing gastric secretion, therefore, seems to us worthy of investigation.

The potential dangers of radiation therapy have been emphasized by several investigators and were well recognized by us. In 1919 Hall and Whipple [12] called attention to the sensitiveness of the mucosa of the small intestine to irradiation and described the epithelial injury and necrosis resulting therefrom. The observation was subsequently confirmed by Denis and Martin,[13] Martin and Rogers,[14] Ivy and his associates [7] and other workers. Wetzel [15] in 1921 described the case of a cachectic woman aged 68 with gastric carcinoma in whom, after two courses of radiation therapy, there was found at autopsy a defect in the anterior wall of the stomach, peritonitis and regional necrosis of the left lobe of the liver, even though there was no change microscopically or grossly in the overlying skin. Case and Warthin [16] found degenerative and necrotic hepatic lesions at autopsy in three cases of carcinoma of the stomach in which intensive radiation therapy had been given. In recent years, however, one of our associates, Dr. Alexander Brunschwig, has had a rather wide experience in the radiation treatment of malignant disease and has found that, on the whole, the abdominal viscera can tolerate fairly large doses quite well. We therefore decided to study the effect of a large but, in our experience, safe dose of radiation on gastric secretion in man.

PROCEDURE

Approximately 100 cases of peptic ulcer, including gastric, duodenal and jejunal lesions, were treated. In eighty-eight of these the effect on the gastric secretion was studied. The amount of radiation employed was considerably less than that used in the treatment of malignant disease and consisted of ten treatments given over a period of eleven or twelve days, five treatments

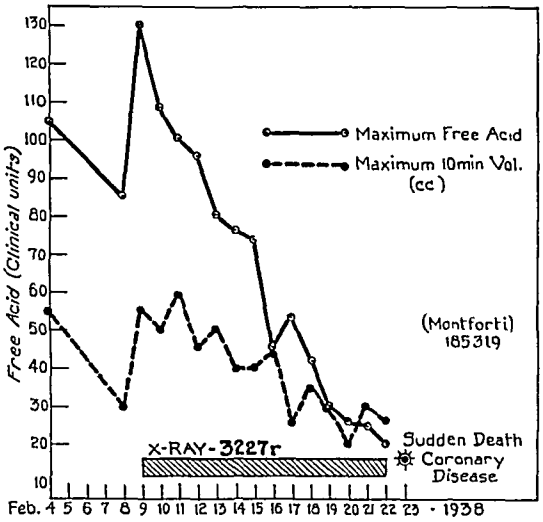

Chart 1.—Effect of radiation therapy on gastric secretion (histamine stimulation).

anteriorly and five posteriorly on alternate days through portals 15 cm. square. The portals were aimed at the upper part of the stomach. Occasionally the relationship of the portals to the stomach was checked fluoroscopically. The dose of radiation through each portal was approximately 1,500 roentgens, measured without back scatter, or a total of 3,000 roentgens. In a few instances a total dosage of 3,600 roentgens was given, and in a few others much smaller doses were used. The roentgen formula was 200 kilovolts, 25 milli-

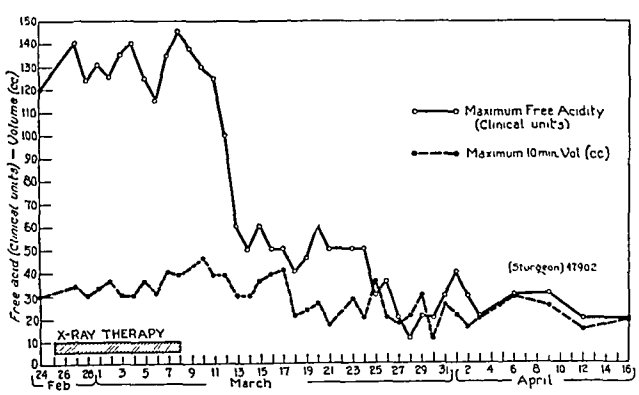

Chart 2.—Effect of radiation therapy (2,960 roentgens) on gastric secretion (histamine), showing marked reduction on daily tests.

amperes, with 1 mm. of copper plus 1 mm. of aluminum filtration, and a focal skin distance of 50 cm., from 32 to 38 roentgens being delivered per minute.

The gastric secretory response was measured by means of the standard histamine test of Bloomfield and Polland,[17] 0.01 mg. of histamine hydrochloride being used per kilogram of body weight. The maximum free acidity and the maximum ten minute volume were considered to indicate the maximum gastric response on a given day and were the points for comparison in constructing the curves. Histamine tests were made at variable intervals during and after therapy.

RESULTS

Some depression of gastric secretion was obtained in every case treated, but the extent and duration of this depression were quite variable. The results are best portrayed by a series of charts of illustrative cases. In one case, as shown in chart 1, the gastric secretory capacity, as judged by daily histamine tests, dropped rapidly during the period of treatment from a maximum free acidity of 130 to a maximum of 20, and the maximum ten minute volume likewise dropped from 60 cc. to 26 cc. In chart 2, on the other hand, no appreciable change occurred during the period of therapy, but a marked drop did occur a few days later—from an average free acidity of 130 to approximately 30 without much change in the volume of secretion. Chart 3 similarly shows very little change during the period of treatment and only a minimum depression later. The free acidity before treatment was 115. It dropped to

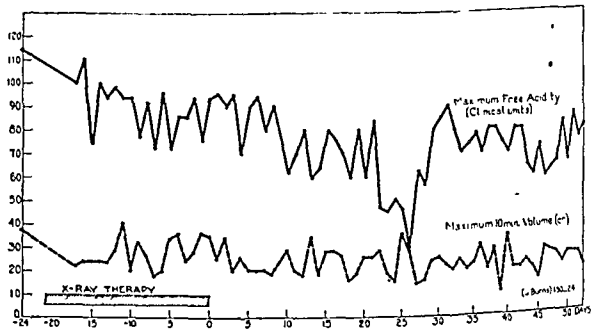

Chart 3.—Effect of radiation therapy (3,600 roentgens) on gastric secretion (histamine). Minimum depression in spite of large dose

30 on one occasion, twenty-six days after treatment, but the daily level ranged around 80, with no decrease in the volume of secretion. Of the eighty-eight cases studied, the depression of secretion observed in this case was less than in any of the others.

The more chronic effects are illustrated in the subsequent charts. In chart 4 it will be seen that a complete achlorhydria to histamine appeared on the twenty-second day and persisted through the ninety-seventh day after therapy. The volume of secretion was greatly reduced. The secretory response gradually returned but at the end of a year had not regained its original level. In chart 5, on the other hand, the period of achlorhydria was of only two weeks' duration and at the end of four months gastric secretion was again normal. An additional course of therapy (1,762 roentgens) had only a temporary effect in terms of free acidity, although the depression of the volume of secretion apparently was more prolonged. Chart 6 likewise shows a temporary initial period of achlorhydria followed by a return to a high secretory response. Charts 7 and 8, by contrast, show the production of a prolonged achlorhydria lasting in each instance six months or more and with profound depression of secretion still present nine months after treatment.

In two instances, marked and prolonged depressions were noted even with small doses of radiation, as may

17. Bloomfield, A. L., and Polland, W. S.: The Diagnostic Value of Studies of Gastric Secretion, J. A. M. A. 92: 1508 (May 4) 1929.

be seen in charts 9 and 10. In fact, as shown in chart 9, the smallest dose used in our series, 1,097 roentgens, was followed by a histamine achlorhydria of three weeks' duration and by a very low secretory response still in effect at the end of five months.

The most frequent complications encountered were those of the well known but poorly understood roentgen sickness. This usually accompanied the first two or three treatments and then disappeared. No correlation was observed between the severity of the sickness and the depression of secretion. Acute anemia was observed in one case. In this instance (chart 10) the treatment was given while the patient was recovering from a massive hemorrhage. Examination of the stools was negative for occult blood, but the blood picture had not returned to normal. After the fifth treatment the erythrocytes suddenly dropped from 3.8 to 2.86 million per cubic millimeter without evidence of hemorrhage. The treatments were therefore discontinued. No other anemia has been observed and no definite or marked anemia has appeared subsequent to therapy. In one case painless diarrhea appeared almost three months after the therapy and proved rather troublesome for two months. It then ceased and the patient has continued in good health. The only serious complication encountered in the series occurred in the patient whose

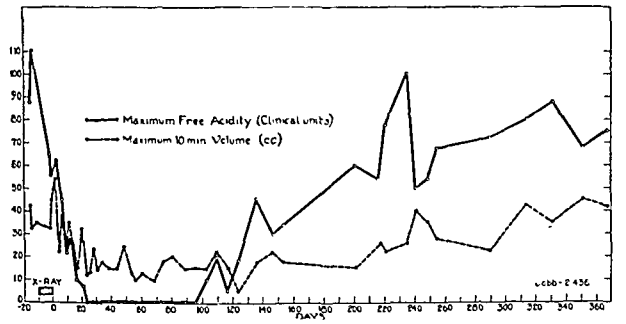

Chart 4.—Effect of radiation therapy (2,930 roentgens) on gastric secretion (histamine). Complete achlorhydria for seventy-two days; marked depression for 216 days; slight depression for 367 days.

course is shown graphically in chart 11. Three weeks after treatment acute pain and muscular rigidity appeared in the upper part of the abdomen suggesting the acute perforation of a viscus. At operation the ulcer appeared to be healed but there was a region of acute necrosis in the left lobe of the liver, presumably radiation necrosis. The overlying skin was normal. The abdominal wall was closed and the patient made an uneventful recovery. It is interesting to note in this case that, although sufficient radiation was delivered to produce local injury to the liver, the effect on gastric secretion was only moderate.

The maximum reduction in the free acidity obtained in the eighty-eight cases is summarized in chart 12, in which the maximum initial response to histamine is compared with the minimum subsequent response. It may be noted that no correlation is seen between the initial level of secretion and the amount of depression. Complete achlorhydria appeared in thirty-five of the eighty-eight cases, the known duration of achlorhydria varying from a few days to six months, as is shown in chart 13.

The susceptibility of the gastric secretory mechanism to irradiation was not related to the initial secretory response of the gastric glands nor was it related to sex or to age, as is shown in chart 14, for the age distribution of those in whom achlorhydria developed was essentially the same as that of the entire group. It likewise did not appear to depend on height or body weight or to be a direct function of depth dose, for of the two patients in whom achlorhydria developed and persisted for approximately six months one was quite thin and the other was very obese.

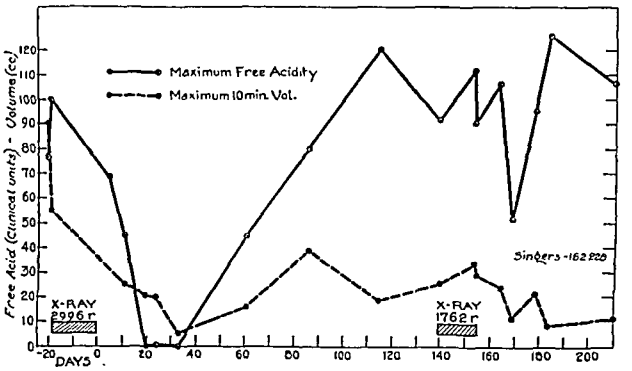

Chart 5.—Effect of radiation therapy on gastric secretion (histamine). Slight effect from second treatment.

MORPHOLOGIC CHANGES IN THE GASTRIC MUCOSA

Dawson[18] in 1925 made a detailed study of the microscopic changes in the gastric mucosa of the dog following irradiation, the observations being summarized as follows:

The reduction and eventual disappearance of acid from the gastric secretion is associated with definite injury to the gastric mucosa. The most striking injury occurs in the superficial portions. Mucous, neck, chief and parietal cells are damaged. The chief cells undergo cytolysis, while the parietal are not so readily broken down. Persisting parietal cells which show no histological evidence of injury are unable to produce acid . . . the necrotic tissue is apparently sloughed, regeneration occurring from below. In regenerated mucosa the thickness is markedly reduced but the structure is histologically normal. The parietal cells show marked variations in staining

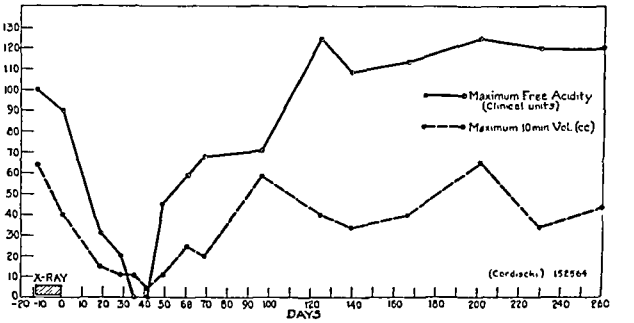

Chart 6.—Effect of radiation therapy (2,930 roentgens) on gastric secretion (histamine). Marked initial temporary depression.

and in nuclear structure. Some cells are pale with a pycnotic nucleus while others stain densely and their nuclei show a definite reticulum.

In two of the cases treated in our series, opportunity arose to study the mucosa in detail. In the first of these, described in connection with chart 1, death occurred of coronary occlusion the day after a course

18. Dawson, A. B.: Histological Changes in the Gastric Mucosa (Pawlow Pouch) of the Dog Following Irradiation, Am. J. Roentgenol. 13: 320 (April) 1925.

of treatment was completed totaling 3,227 roentgens in a period of thirteen days. In this case of penetrating duodenal ulcer with severe pain and with moderate diabetes mellitus, thyrotoxicosis and coronary sclerosis, death was definitely due to the rupture of an atheromatous plaque in the right coronary artery (autopsy). Extensive coronary sclerosis was present with multiple healed infarcts of the myocardium. There were no acute changes in the heart muscle and there was no

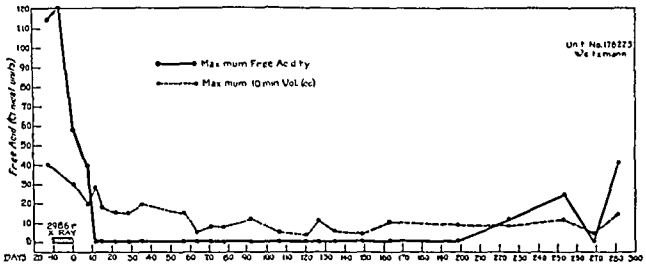

Chart 7.—Effect of radiation therapy on gastric secretion (histamine stimulation). Prolonged achlorhydria.

evidence clinically or pathologically to incriminate the roentgen therapy as a precipitating factor in the death. Dr. H. G. Wells and Dr. Eleanor Humphreys of the department of pathology studied the material and Dr. Humphreys has made the following report:

The gastric mucosa is everywhere profoundly altered, especially in the fundus. While it is impossible to exclude the effects of postmortem changes, mucous cells are absent from the depths of the gastric pits as well as from the surface. The most striking changes are seen at, and just below, the base of the necks of the glands. Here the glandular pattern is distorted, and sloughing, degenerating cells are mingled with living cells. The degenerating cells stain deeply, have distorted, dark nuclei and often appear fused into ribbons or clumps. A few cytoplasmic masses without nuclei are seen. Most of the surviving cells appear abnormal. They have pale cytoplasm and vesicular nuclei, often with large nucleoli. There is an unusual variability in the size of these cells and in the size and number of their nuclei and nucleoli. Some are huge, syncytial masses with from five to ten nuclei. Mitotic figures are few and are seen only in cells of normal size. Deeper in the glands there are minor degenerative changes (nuclear pyknosis, cytoplasmic vacuolization and the like) in both chief and parietal cells. Acute and chronic inflammatory changes are present—inter-

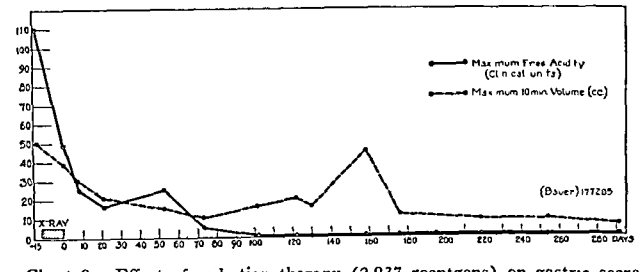

Chart 8.—Effect of radiation therapy (2,937 roentgens) on gastric secretion (histamine). Prolonged achlorhydria.

stitial foci of lymphocytes and plasma cells, in some cases with a few eosinophils and neutrophils—and accumulations of neutrophils within the lumens of some of the glands.

Comment.—It is interesting that this mixture of degenerative hyperplastic reaction is seen in the region which is the normal site of greatest cellular growth—at, and near, the necks of the glands. It is also interesting that the changes at the lower end of the esophagus, bordering the cardia (absent at a higher level), are qualitatively similar with an intermixture of cell degeneration and hyperplasia in the germinal basal layer, and with entirely similar large and multinucleate cells in the layers above. From other studies that I have made I think that the cell hypertrophy, giant-cell formation and the like of the type seen in these two regions represent an abnormal hyperplastic response to injury—a probably unsuccessful response. Transition forms seem to me to indicate that the injured cell increases in size, its nucleus enlarges and divides (amitotically), but no division of cells follows. The end stage is a huge cell—with multiple nuclei of varying sizes—which presumably degenerates.

The second patient received 2,937 roentgens from June 28 to July 9, 1937, and died Jan. 29, 1938, of malignant nephrosclerosis. The maximum free acidity (histamine) before treatment was 102. Complete achlorhydria (histamine) was present Aug. 23 and 30, Sept. 7, Oct. 2 and 30, Nov. 24 and Dec. 28, 1937. The histologic study made by Drs. Wells and Humphreys and reported by Dr. Humphreys follows:

Multiple sections show that there is a widespread, chronic gastritis, with focal thinning of the mucous membrane and both atrophy and focal hyperplasia of gastric glands. There is a general increase of fibrous tissue in the mucosa with a broad zone between the muscularis mucosae and, especially in the most thinned regions, increased amounts between the glands. This is heavily infiltrated with leukocytes—most of them plasma cells—but with a few neutrophils and occasional eosinophils. Even in the best preserved region—in the fundus near the greater curvature—glands are atrophic; many are lined by

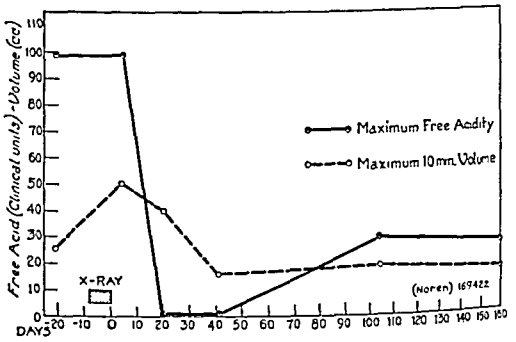

Chart 9.—Effect of radiation therapy (1,097 roentgens) on gastric secretion (histamine). Prolonged depression with rather small dose.

small, indeterminate cells and relatively large normal-appearing oxyphils. Chief cells are few. In several sections from greatly thinned regions—on or near the lesser curvature—the glands are very small, distorted and far apart and, structurally, look like atrophic tubules from the pyloric region. Fewer in number but scattered throughout the atrophic tubules are others which are much larger, lined by closely crowded, tall cells with dark basal nuclei. These look much more like intestinal crypts than gastric glands. The mucosa of the pylorus is not atrophic, its glands are hyperplastic and there is one focus of glands of the intestinal type which structurally resemble the glands of an adenoma. Mitotic figures are relatively numerous in most of the glands of the intestinal type. Changes in the surface epithelium could not be made out because of postmortem changes.

Comment.—I can find no changes here which could with certainty be attributed to irradiation or, conversely, which could not be accounted for by chronic, atrophic gastritis. It is the absence of significant chronic changes in the other case which makes it possible, with reasonable certainty, to attribute the alterations to the recent injury by x-rays.

In both cases the autopsies were unavoidably delayed, and the consequent postmortem changes interfered to a certain extent with the appraisal of the cellular alterations.

A third patient received 2,074 roentgens between Oct. 4 and 12, 1937. November 17 a posterior gastroenterostomy was undone. A piece of mucosa was

removed from the anterior wall of the fundus of the stomach for microscopic examination. Dr. Humphreys was unable to make out anything unusual. "There may be very slight mucosal atrophy (some of the glands seem small). The acid-secreting cells are certainly numerous. There are no significant inflammatory changes." A histamine test the day before the operation disclosed a maximum free acidity of 48 in the presence of a functioning gastro-enterostomy.

The gross appearance of the gastric mucosa in many of the patients in this series was studied gastroscopically from time to time by Dr. Rudolf Schindler, to whom we are greatly indebted. These observations will be reported in greater detail in a later communication. It may be noted at this time that the alterations were not entirely constant or consistent. Superficial gastritis of varying severity was frequently found. Definite necrosis of the mucosa was never observed. Hypertrophic gastritis frequently disappeared. In many instances the mucosa appeared normal even during the period of achlorhydria to histamine. The following gastroscopic protocols of the patient mentioned in connection with chart 8, who continues to have a histamine achlorhydria 322 days after the last radiation treatment, are illustrative. The patient received 2,937 roentgens between June 26 and July 8, 1937.

June 30, 1937: Circumscribed hypertrophic gastritis of the posterior wall of the stomach.

October 15: In the antrum and in the lower portions of the body, small amounts of adherent mucus were observed. The upper portions were entirely normal. Impression: Slight superficial gastritis.

December 3: The entire stomach was seen. The pylorus was round and open and did not contract during the examination. There was one mucosal hemorrhage, pinhead sized, in the greater curvature of the antrum, lying in normal mucous membrane. The mucosa of the lesser curvature and of the anterior wall of the body was covered by patches of gray, dirty, adherent mucus. In the lesser curvature a very small, shallow, elliptic, yellowish gray ulceration, sharply defined, was seen. Impression: (1) very small ulcer in the lesser curvature, (2) one mucosal hemorrhage in normal mucosa, (3) extensive superficial chronic gastritis of the body.

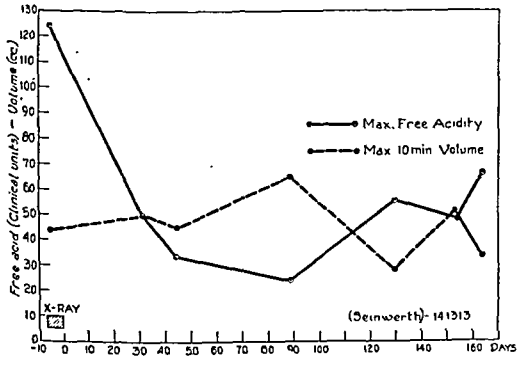

Chart 10.—Effect of radiation therapy (1,472 roentgens) on gastric secretion (histamine). Marked reduction with small dose.

Jan. 5, 1938: No ulcer was seen. The gastric mucosa of the antrum and the body was a little bit mottled and contained some patches of adherent mucus. Impression: (1) no ulcer visible, (2) very slight superficial gastritis.

April 1: The stomach was well seen. The mucosa looked normal today. Impression: Normal mucosa.

May 16: The entire mucosa of the antrum as well as of the body presented layers of adherent mucus which did not contain air bubbles: Impression: Extensive superficial gastritis of the entire stomach.

It may be added incidentally that the patient has been without symptoms and perfectly well clinically since his admission to the hospital June 5, 1937.

The status of the ulcer in each case was studied carefully but the observations are not included in this report because the patients were given the standard Sippy acid neutralization management in addition to the radiation therapy and also because insufficient time has elapsed for valid appraisal of the method. Various workers [19]

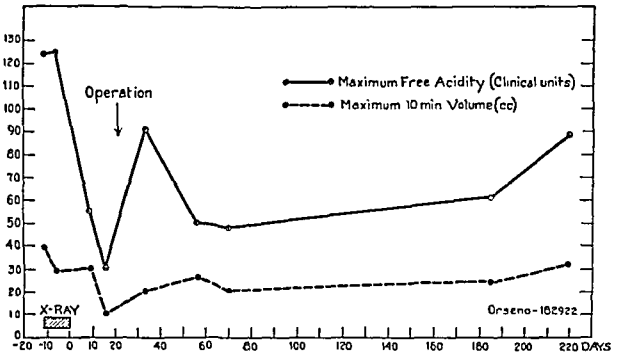

Chart 11.—Effect of radiation therapy (2,965 roentgens) on gastric secretion (histamine stimulation). Moderate reduction only in spite of injury to liver.

have used roentgen rays in the treatment of ulcer since the initial report by Wilms [20] in 1916. The results have been debatable, particularly if one recalls the demonstration by Sandweiss [21] that remissions in the symptomatology of peptic ulcer can be induced psychotherapeutically by the intravenous injection of distilled water. The largest series of cases described is that of Matoni,[22] who treated 140 patients with complete healing of the ulcer in 77.1 per cent, improvement in 13.6 per cent and no improvement in 9.3 per cent. The question arises as to whether the improvement resulted from the therapy or was independent of it. Great care must

be exercised in the evaluation of therapeutic "results" in the treatment of peptic ulcer. Our study of this group of patients is being continued in the hope that in time we may be able to evaluate more satisfactorily the role of radiation therapy in the management of

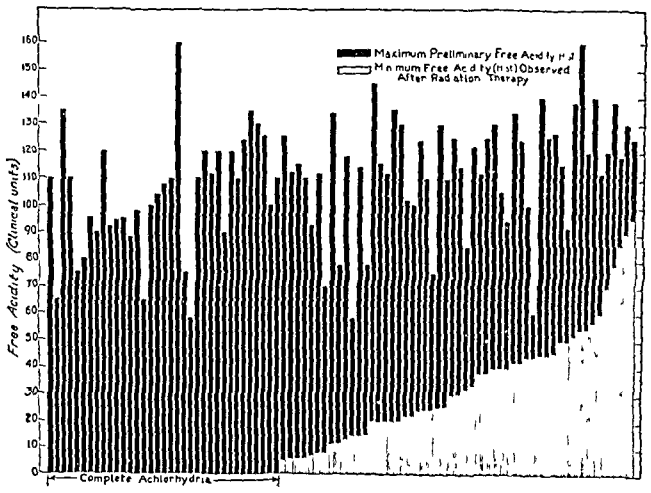

Chart 12.—Maximum reduction in free acidity (histamine) following radiation therapy: Summary of eighty-eight cases.

ulcer. It is perhaps significant that during the phase of achlorhydria relief of symptoms invariably occurred, accompanied in many cases by objective (roentgenologic or gastroscopic) evidence of progressive healing of the ulcer. In no instance did the symptoms recur or the ulcer increase in size during the period of achlorhydria. The final effect of irradiation, not only on the gastric

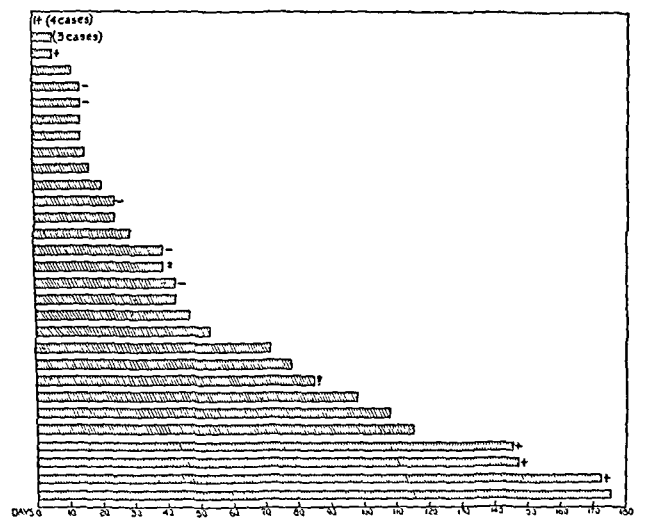

Chart 13.—Known duration of achlorhydria (histamine): thirty five cases.

secretion and the course of the ulcer but also on the normal tissue within the field of radiation, remains still to be determined.

SUMMARY AND CONCLUSIONS

1. Radiation therapy directed toward the upper two thirds of the stomach and applied in the manner that has been described in doses totaling from 1,100 to 3,600 roentgens definitely depresses gastric secretion in man.

2. The extent and duration of this depression are extremely variable and as yet unpredictable.

3. Development of a complete achlorhydria to histamine was demonstrated in thirty-five of the eighty-eight cases studied. The duration of the achlorhydria was shown to vary from a few days to more than nine months.

4. Susceptibility to irradiation does not depend on age, sex, body weight or initial glandular activity.

5. Morphologic evidence of cellular injury in the mucosa following irradiation consists in the demonstration (*a*) gastroscopically, of superficial gastritis variable in severity and inconstantly present, and (*b*) histologically, of alterations in cellular structure similar to those described by Dawson in the dog.

6. The potential dangers of radiation therapy used as described and in total doses of 3,000 roentgens or greater are those arising from injury to other organs, notably the intestine and the liver. Localized liver necrosis occurred in one case; in another a rather troublesome diarrhea appeared, presumably due to intestinal injury, and in a third a sudden but not serious drop in the red cell count was noted. No evidence of renal or pancreatic damage was observed in this series.

ADDENDUM

In the interval between completion of the paper and receipt of the proof, free acidity returned finally in the case illustrated in chart 8, in which the period of

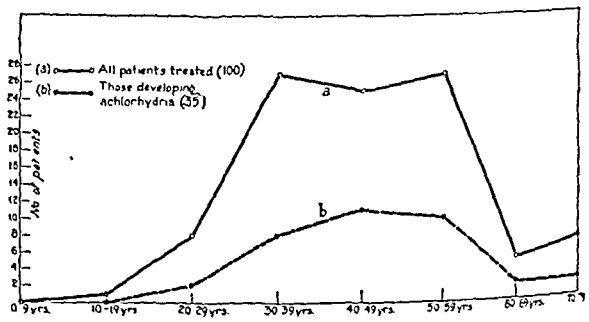

Chart 14.—Age distribution (decades).

achlorhydria was the longest that occurred in our series. The maximum free acidity (histamine) was 8 on the 405th day after therapy, 13, 15, 11 and 8 on the 444th, 472d, 499th and 530th days respectively. Repeated gastroscopic examinations have disclosed no evidence of recurrent ulcer but have revealed a persistent superficial gastritis. The patient, however, has continued in excellent clinical health without distress or symptoms of any kind since the institution of treatment twenty months ago.

Reference should also be made to the fact that, while the results of the combined radiation and Sippy management in the group mentioned have been satisfactory to us on the whole, there have been at least two notable exceptions—one gastric ulcer which did not heal and one recurrent gastric ulcer (cases 6 and 11 reported by Palmer, Schindler and Templeton). Achlorhydria was not produced by the radiation in either case.

An additional series of cases has been studied with a total radiation dosage of only 1,200 roentgens (three treatments of 200 roentgens each anteriorly and posteriorly), but the depression of secretion has been much less marked. A third series is now being undertaken with five treatments anteriorly and five posteriorly of 225 roentgens each, a total dosage of 2,250 roentgens, the formula being the same as in the initial series.

SULFAPYRIDINE IN THE TREATMENT OF PNEUMONIA IN INFANCY AND CHILDHOOD

The results of the use of 2-(para-aminobenzenesulfonamido) pyridine, officially known as sulfapyridine, in animal experiments and the favorable effects obtained with it in the treatment of pneumonic infections in human beings warrant a trial of this drug with infants and children under carefully controlled conditions. Furthermore, whenever possible the results of such a study should be subjected to statistical analysis. For this purpose we have employed the methods of Fisher [1] because they appeared to be the most appropriate for the analysis of a small series.[2] Both the value and the possible harmful effects of sulfapyridine must be determined as soon as possible so that physicians may know how widely it should be used. No attempt will be made to review the literature on this subject, since adequate reviews are available.[3]

In a study of any treatment of pneumonia in children the low case fatality rate makes it essential that conclusions be based on other considerations, such as the course and duration of the disease and the incidence of complications. Furthermore, since the severity, type and complications of pneumonia may vary from one year to another, it is important that the group treated with sulfapyridine and a control group be studied simultaneously.

PLAN OF THE STUDY

When a diagnosis of pneumonia was made or suspected on a patient's admission to the hospital, he was allocated to one of two groups designated respectively "control" and "sulfapyridine" in such a way as to have the two groups, when the study was completed, as comparable as possible as to age, the duration of the pneumonia and its severity at the time of admission. All patients except those suffering from empyema on admission were included in one or the other of the groups.

Experience with other forms of treatment of pneumonia indicates that the results are in general related to the day of the disease on which treatment is instituted. It was decided therefore not to delay medication until bacteriologic or roentgenologic confirmation was obtained. In the sulfapyridine group the administration of the drug was begun as soon as blood, and material from the throat, had been secured for culture. A number of children who received sulfapyridine but who later were found not to be suffering from pneumonia were excluded from the study.

Early in the study patients who were treated with sulfapyridine were administered aliquot doses every three hours, every four hours or, in a few instances, every six hours in such an amount that 1 grain (0.06 Gm.) per pound of body weight was received each twenty-four hours, a large initial dose of one-half the amount calculated for the twenty-four hours being administered on admission in order to obtain quickly a therapeutic level in the blood. In accordance with the procedure which is usually adopted with sulfanilamide medication, sodium bicarbonate was administered in doses equal to those of sulfapyridine. In most instances medication was continued until the patient had been afebrile for about five days. Later in the study 1½ grains (0.1 Gm.) of sulfapyridine was administered per pound of body weight each twenty-four hours in order that the effects of higher levels in the blood might be observed. With two patients who were not responding well it was found that the level of sulfapyridine in the blood was less than 2 mg. per hundred cubic centimeters, and larger doses were then administered until the level rose. The drug was powdered and suspended in a half ounce or so of water for oral administration, and, since sulfapyridine is a relatively insoluble compound, fluids were administered liberally after each dose to promote its absorption.

At the beginning of the study determinations of the levels of free sulfapyridine in the blood were made on oxylated venous blood, the method of Marshall and Litchfield [4] with sulfanilamide being employed as a standard and a correction factor for sulfapyridine being determined. Later a photoelectric colorimeter (Evelyn) was used so that determinations could be made on 0.1 cc. of capillary blood from finger or ear, thus making possible daily determinations in the case of even the smallest patients.[5] So far as practicable, transfusions, oxygen therapy and other nonspecific measures were used for the same indications in the two groups.

Since sputum is not available or is difficult to obtain from children, material for culture was secured by swabs introduced deep into the oropharynx, with the patient's head hyperextended and his tongue sharply depressed, the swab being held in the throat until coughing was elicited. Duplicate specimens were obtained in this manner on admission of the patient to the hospital. One of these was planted in neopeptone-dextrose broth, and the other was streaked onto a blood agar plate. After incubation of from twelve to twenty-four hours the broth cultures were typed for pneumococci by the Neufeld method and the blood agar plates were examined for predominating organisms. When a broth culture yielded no pneumococci, two mice were inoculated intraperitoneally and the peritoneal exudate was subsequently examined. Even when broth cultures yielded pneumococci, mice were employed at times in the attempt to find additional types which might have been missed on direct examination of the broth cultures. Duplicate specimens from the throat were obtained again within twenty-four to forty-eight hours after admission and subjected to the procedures described.

Merck & Co., furnished the sulfapyridine (dagenan) used.

5. For determinations with the photoelectric colorimeter the method of Marshall and Litchfield was modified by diluting 0.1 cc. of blood to 10 cc. with the saponin and acid solutions. The final concentration of trichloroacetic acid remained at 3 per cent (personal communication from Dr. Marshall).

Blood for culture was obtained from all patients on admission to the hospital, from 3 to 5 cc. being placed in tubes of neopeptone-dextrose broth and from 3 to 5 cc. in flasks of dried citrate so that colony counts on poured agar plates could be made.

When a myringotomy was performed the contaminated myringotomy knife was used for inoculation into a tube of the broth. In addition the material obtained from a swab was inoculated into broth and streaked on blood agar plates. When the patient's ears were draining on admission to the hospital the discharge was cultured in a similar manner. When bilateral suppurative otitis media was present the discharge from each ear was separately cultured.

Fluids obtained by thoracentesis were cultured and the organisms identified in the usual manner.

Special arrangements were made by which all material for cultural studies and for chemical analyses were sent to the laboratories without delay.

At the Children's Hospital roentgenograms were made at intervals of two or three days from the time of admission until there was complete resolution of the exudate; at the Cincinnati General Hospital they were made less frequently.

The diagnosis of pneumonia was made by physical examination and observation of the clinical course; roentgenograms confirmed the diagnosis in all but three cases, but in these the clinical diagnosis was sufficiently certain to justify their inclusion in the study. It appeared proper to analyze croupous pneumonia and bronchopneumonia together, without reporting them in two groups. The differentiation between these two types of pneumonia even with the assistance of roentgenograms is not easy, and, furthermore, the course

of the pneumonic symptoms, an important differential point, was so influenced by sulfapyridine therapy that it was no longer helpful. The diagnoses as made by us are, however, listed in table 1.

To facilitate the keeping of records and the final analysis of the cases, a special graphic chart was evolved on which to record the material contained in the accompanying table and chart, i. e. the temperature, pulse rate, respiratory rate, treatment and results of clinical and laboratory observation. The data were recorded and physical examinations performed, to insure uniformity, by two members of the group making the study, one observing closely the patients in the Children's Hospital and the other those in the Cincinnati General Hospital. Frequent conferences were held to correlate the observations. The bacteriologic examinations and the determinations of the sulfapyridine levels of the blood were all made in the Children's Hospital by the same group of workers. It may be stated therefore that the patients in the two hospitals were observed under sufficiently similar conditions to warrant their combination in the study.

ANALYSIS OF THE MATERIAL

The course of pneumonia was observed and analyzed in seventy of our patients, thirty-five of whom received sulfapyridine. It happened that twenty-two in each group were patients in the Children's Hospital and thirteen in each group patients at the Cincinnati General Hospital.

Table 1 demonstrates the similarity of the control group and the sulfapyridine group with respect to the age of the patient, the severity of the pneumonia, the estimated duration of the pneumonia when the patient was admitted to the hospital, and the type of pneumonia. This satisfactory similarity was achieved in a series of this small size by the deliberate distribution of the patients as previously described.

* This includes all pneumococci observed, whether alone or in combination with other types.

Tables 2 and 3 show the types of pneumococci observed in the cultures of material from the pharynx. The number of cases is too few to warrant analysis of the type of pneumococci in relation to severity or type of pneumonia or effect of therapy.

Of the seventy patients only one, who happened to belong in the sulfapyridine group and who later had empyema, had bacteremia, this being due to type VI pneumococci. This patient subsequently recovered.

In a later and more complete report there will be presented the results of the cultures of material from the ears and pleura.

Two patients who died within twenty-four hours of admission to the hospital were not included in this study. One was moribund on admission and received

his initial dose of sulfapyridine but died within four hours. The seventy patients included in the study all recovered from their pneumonia.

ANALYSIS OF THE RESULTS

1. *The Course of the Pneumonia.*—The course of the pneumonia in sixty-six cases could be observed closely from admission to the hospital until recovery in a manner satisfactory for statistical analysis. Symbols were placed on the charts marking the first day on which there was a significant fall in temperature, the first day of clinical improvement which was subse-

quently maintained, and the first day on which recovery could be considered from a clinical standpoint to have occurred, as demonstrated in the accompanying chart. There were thirty-three patients in the control group and thirty-three in the sulfapyridine group. The remaining four patients of the original seventy were not included in this particular part of the study because three of them acquired parapneumonic empyema, so that the termination of their pneumonia could not be accurately ascertained, and in the fourth an adequate concentration of sulfapyridine could not be maintained in the blood and the course of his disease was not therefore considered to be that of pneumonia affected by sulfapyridine.

In the control group, as demonstrated in table 4, the patients, on an average, manifested their first maintained clinical improvement late in the seventh day from the onset of their pneumonia, their temperature fell significantly early in the ninth day and they could be considered as having recovered early in the twelfth day. In the sulfapyridine group, on an average, the patients manifested their first maintained clinical improvement late in the fourth day from the onset of the pneumonia, their temperature fell significantly late in the fifth day, and they could be considered as having recovered by the middle of the eighth day. Thus, as estimated from the temperature curves and the clinical impressions of the time at which improvement and recovery occurred, patients not receiving sulfapyridine had, on an average, three or four more days of illness than patients treated with sulfapyridine.

When the data are analyzed from the point of view of the duration of the pneumonia after the beginning of hospital treatment, the patients in the control group, on an average, manifested their first maintained clinical improvement early in the fifth day, their temperatures fell significantly early in the sixth day and they could be considered as having recovered late in the ninth day.

TABLE 4.—*Clinical Results in Sixty-Six Cases of Pneumonia* *

	Control Group, 33	Sulfapyridine Group, 33	Difference in Days	p†
Mean day of pneumonia at				
Clinical improvement	7.0	4.0	3.0	<0.01
Significant fall in temperature	8.1	4.7	3.4	<0.01
Clinical recovery	11.2	7.5	3.7	<0.01
Mean day of treatment at				
Clinical improvement	4.4	1.9	2.5	<0.01
Significant fall in temperature	5.3	1.9	3.4	<0.01
Clinical recovery	8.9	4.7	4.2	<0.01

* The data in this table were analyzed by the comparison of two means (Fisher,[10] section 24.1, p. 123).

† p = percentage chance that a deviation as great as or greater than that observed would arise by chance alone, any value of p less than 0.05 being significant.

In the sulfapyridine group, on an average, the patients manifested their first maintained clinical improvement and their first significant fall in temperature late in the second hospital day and could be considered as having recovered late in the fifth day. Thus, while under observation in the hospital, patients not receiving sulfapyridine had, on an average, three and one-half more days of fever and four more days of illness than patients treated with sulfapyridine.

As seen from the values of "p" in the last column of table 4, there is a real significance in the difference between the duration of the disease in the sulfapyridine group and in the control group.

2. *The Incidence of Complications.*—The occurrence of suppurative complications in the two groups of patients is analyzed in table 5. Although complications considered as a whole were less frequent in the sulfapyridine group than in the control group, statistical analysis does not prove that this difference is significant ("p" is between 0.3 and 0.2). However, the difference in the occurrence of suppurative otitis media in the two groups suggests that for this complication the difference might be a real one ("p" is just over 0.05).

3. *Failures and Relapses.*—Two patients receiving sulfapyridine pursued the characteristic course of pneumonia without apparent effect from the drug, although adequate levels were maintained in the blood. The treatment of the third patient must be considered as a failure, since the course of his disease was apparently not shortened. In his case it was impossible to secure continuously a level of the drug in the blood above 2 mg. per hundred cubic centimeters, but it is worth while noting that when the level was high his temperature fell and temporary improvement occurred and that when the level was low his fever recurred and he appeared more acutely ill. This sequence of events was repeated three times before the pneumonia terminated in recovery.

TABLE 5.—*Complications Which Developed in the Hospital in Seventy Cases of Pneumonia*

	Control Group	Sulfapyridine Group
Catarrhal otitis media	3	5
Suppurative otitis media	12	5
Acute mastoiditis	2	0
Empyema	3	1

χ^2 = 4.1159 — n = 3 — p is between 0.3 and 0.2.

Three of the patients in the sulfapyridine group and one in the control group had relapses. The three patients treated with sulfapyridine had manifested satisfactory initial responses to the drug. One had four relapses but responded fairly well to each renewed administration of sulfapyridine.

4. *The Duration of Abnormal Roentgenographic Densities.*—When the time at which roentgenographic evidence of pneumonia disappeared in twelve patients in the sulfapyridine group was compared with the time at which it disappeared in eight patients in the control group, no statistically significant difference was found ("p" = 0.5).

5. *Concentration of Sulfapyridine in the Blood.*—Since we were not employing the micromethod at the beginning of the study, there is available for the thirty-five patients who received sulfapyridine a total of only 121 determinations of the level of the drug in the blood. The average level was 4.7 mg. per hundred cubic centimeters, the highest 23.4 mg. and the lowest a trace. When the levels of the several determinations per patient were averaged the range was from 1.7 to 15.0 mg. per hundred cubic centimeters.

In several cases the levels of sulfapyridine in the blood were obtained at intervals of two hours. Although the levels in these cases were different, in each one a level obtained within three hours after the large initial dose of sulfapyridine was administered was maintained rather constantly for twenty-four hours.

Eliminating two patients—one whose highest blood level was 23.4 mg. and whose average level was 15 mg.

per hundred cubic centimeters and another who showed only a trace of the drug on one determination and whose blood levels could not be averaged—the average level in the blood of twenty-five patients receiving 1 grain of sulfapyridine per pound of body weight each twenty-four hours was 3.8 mg. per hundred cubic centimeters; for eight patients receiving 1½ grains per pound it was 4.6 mg. The average levels for these patients according to age were as follows: under 11 months, 4.1 mg.; from 12 to 23 months, 4.1 mg.; from 2 to 4 years, 3.6 mg., and 5 years and over, 4.4 mg.

Twenty children who made a favorable response to the drug within twenty-four hours of the beginning of its administration had at the time of response a mean level of sulfapyridine in the blood of 4.51 ± 0.31 mg. per hundred cubic centimeters (standard deviation of 1.40 ± 0.22 mg. per hundred cubic centimeters). Children manifesting a delayed response, no response or relapse had approximately the same average levels.

The optimum dosage of sulfapyridine needs further study. The figures reported here suggest that a dosage which secures a level of the drug in the bood of approximately 4 mg. per hundred cubic centimeters brings about a satisfactory response.

6. *Toxic Effects of Sulfapyridine.*—Eleven of the patients in the control group manifested cyanosis when they were admitted to the hospital, this symptom disappearing as improvement or crisis occurred. In the sulfapyridine group sixteen children manifested cyanosis on admission and eight children did not have this symptom at that time but acquired it while receiving the drug. Seventeen of these twenty-four cyanotic patients in the sulfapyridine group continued to manifest cyanosis after their temperature fell to normal; but of these, sixteen lost their cyanosis before the end of a period of five days subsequent to the fall in temperature and while they were still receiving sulfapyridine. Since none of our patients had cyanosis to a degree to cause concern, we did not feel that it was necessary to determine the amount of methemoglobin in the blood. It is worth while noting that the cyanosis seen in our patients receiving sulfapyridine was much less than that present in patients receiving equal amounts of sulfanilamide.

In the sulfapyridine group fifteen patients manifested the symptom vomiting, but so did eleven patients in the control group. There was no definite time relationship of the vomiting to the administration of sulfapyridine. In none of the treated patients was vomiting so severe that it was necessary to discontinue the use of the drug, and in all cases vomiting soon ceased although administration of the drug was being continued.

Irritability was noted in sixteen patients in the sulfapyridine group, as compared with eleven in the control group.

In two of the patients in the sulfapyridine group generalized rubelliform maculopapular cutaneous eruptions developed, these eruptions disappearing when administration of the drug was discontinued.

Complications such as icterus, acute hemolytic anemia, granulocytopenia, acidosis, and fever which could unquestionably be attributed to sulfapyridine were not encountered.

In this study therefore the toxic effects of sulfapyridine were negligible or slight. This is at variance with certain other reports.

SUMMARY AND CONCLUSIONS

1. In a study to determine the value of sulfapyridine in the treatment of pneumonia in infants and children, no distinction was made between croupous pneumonia and bronchopneumonia. We believe that it is necessary to study a control group simultaneously with a "sulfapyridine group" and to compare such factors as age, severity of the pneumonia, and the time at which there is clinical improvement, a significant fall in the temperature and clinical recovery. An analysis of these factors is especially important in a study of pneumonia in early life, since the case fatality rate is so low that it cannot be employed as a criterion for comparison. For example, all the patients in both groups in this study recovered.

2. We observed seventy patients with pneumonia, half of whom received sulfapyridine. Analysis of the characteristics of the disease in the sulfapyridine group and in the control group demonstrated that the two groups were suitable for comparison.

3. The administration of sulfapyridine apparently shortened the course of the pneumonia by approximately three to four days. By statistical analysis it was demonstrated that the fall in temperature and the clinical recovery were significantly earlier in the sulfapyridine group than in the control group.

4. The series of cases was too small to allow evaluation of the effect of sulfapyridine in preventing complications of pneumonia.

5. Two of the patients in the sulfapyridine group manifested a course apparently uninfluenced by the drug; two other patients had a relapse, and one had a series of relapses whenever the use of the drug was discontinued. One patient in the control group had a relapse.

6. The optimum dosage of sulfapyridine needs further study. Our observations indicate that a dosage which secures a level of free sulfapyridine in the blood of approximately 4 mg. per hundred cubic centimeters is therapeutically adequate.

7. There were marked individual variations in the levels of sulfapyridine in the blood obtained with the doses we employed, namely from 1 to 1½ grains (0.06 to 0.1 Gm.) per pound of body weight each twenty-four hours. To be sure that an adequate dosage is being maintained it is necessary to examine the blood frequently; that is, at least daily. The use of a photoelectric colorimeter makes it possible to perform determinations on 0.1 cc. of capillary blood.

8. Vomiting and cyanosis were present in about half the patients receiving sulfapyridine. The cyanosis was not sufficient to cause concern in any instance. A number of patients in the control group also manifested cyanosis and vomiting during the acute stage of their pneumonia. Two patients receiving sulfapyridine had cutaneous eruptions. None of the severer drug reactions were encountered.

9. These preliminary observations on the effect of sulfapyridine on the pneumonias of infancy and childhood and the apparent low toxicity of the drug in the doses we employed are sufficiently encouraging to warrant further study. It is our intention to continue to use the drug and to observe its effect in cases in which there are complications and, if possible, to evaluate its optimum dosage.

SUCCESSFUL TREATMENT OF DIABETIC GIRLS WITH PROTAMINE ZINC INSULIN

PRISCILLA WHITE, M.D.
AND
LOVILLA WINTERBOTTOM, R.N
BOSTON

Criticism adverse to the successful use of protamine zinc insulin in the treatment of diabetes led Dr. Joslin to request a brief summary of our experience with 128 diabetic girls at the Clara Barton Homestead Camp during the summer of 1938. The campers included children of all age groups, durations of diabetes and social classes. Their ages ranged from 5 to 20 years and the duration of diabetes from a few months to seventeen years. Ninety-eight were patients previously treated at the George F. Baker Clinic; thirty were referred from other sources. Of the number, eighty-four paid nothing toward the maintenance of the camp, forty contributed something and four paid the full fee or more.

The rules governing the treatment of our own patients prior to camp had been calories per day prescribed for age, 1,000 in infancy and 100 calories added per year of age up to 2,200 for adolescent girls; for each 2 Gm. of carbohydrate, 0.9 Gm. of protein and 1 Gm. of fat had been administered in three meals and three small lunches. Protamine insulin had been used in nearly all cases. Similar diets were continued at camp. One child required no insulin, four who previously had been treated with protamine zinc insulin were treated with regular insulin at parental request, eleven were treated with protamine zinc insulin alone and 112 with regular insulin plus protamine zinc insulin. The results of previous treatment on the physical state of the child will be reported later in detail by White and Wagner but to cursory inspection and examination the average diabetic girl of this group, even after several years' duration of the disease, was taller than the Baldwin and Wood standard by 1.2 inches, weighed 3.6 pounds more than the average for height and age and was free from complications.

The reports unfavorable to protamine zinc insulin which we wish to refute here, claim that the disease is not well controlled, that fluctuations of glycosuria occur, that severe reactions are prevalent and that diets liberal in carbohydrate and calories cannot be employed. For purposes of this study we selected on the basis of an average two week period of observation data of the second, tenth and twelfth camp days and have summarized these in table 1. In the table the children are grouped by age and for each age the number of cases, the average duration of the disease, average weight and height, and average of all blood sugar values for fasting, 11 a. m. and 4 p. m. The diet in carbohydrate, protein and fat, regular insulin and protamine insulin with the corresponding total quantities of sugar excreted are recorded for the second, tenth and twelfth days. From this table we excluded the child who required no insulin and the four treated with regular insulin only.

Control of diabetes was measured by the amount of dextrose in grams excreted in the twenty-four hour specimen of urine and the level of the blood sugar examined fasting, at 11 o'clock in the morning and at 4 in the afternoon. All three analyses were usually made on the same day. Control of diabetes based on the amount of dextrose excreted in twenty-four hours was classified as perfect if the patient was aglycosuric, excellent if the output in grams was 10 per cent or less than the carbohydrate intake, good if from 10 to 20 per cent and poor if more than 20 per cent. Thus in table 2 we record that only 4 and 6 per cent of the cases showed poorly controlled diabetes on the twelfth and tenth days respectively, and by our own definition 96 and 94 per cent, though not perfectly controlled, in the majority of instances were well controlled. It was also gratifying to note among children largely of the underprivileged class and many of whom were in the adolescent age group, that only 29 per cent had poorly controlled diabetes when they arrived at camp. This should be emphasized because some of these girls traveled long distances from other states. In fact, the homes of the patients were as follows: Massachusetts seventy-six, New York fourteen, Rhode Island twelve, Connecticut five, New Jersey five, Maine three, New Hampshire three, Vermont three, New Brunswick two, and Mississippi, Virginia, Georgia, Nebraska, Philippines, one each.

From the George F. Baker Clinic of the New England Deaconess Hospital, Elliot P. Joslin, medical director.

The average blood sugar was studied for age groups from 5 to 20 years and it showed an even more favorable state of control because it was nearly normal, whether analyzed fasting, at 11 o'clock or at 4 o'clock.

Fluctuations in the degree of glycosuria did occur. Thus, five of our thirteen groups divided according to present age showed more sugar in the urine on the twelfth than on the tenth day with almost exactly equal average diets and doses of insulin. This amounted to an excess of 3, 6, 7, 17 and 19 Gm. for each age period.

Severe hypoglycemic reactions occurred in 15 per cent, but 85 per cent showed none or very mild ones. Reactions were classified as severe if the patient lost consciousness or had convulsive seizures, or nausea and vomiting. None required treatment with dextrose intravenously; carbohydrate was administered by mouth or epinephrine by subcutaneous injection. The carbohydrate of the diet in the two week interval exceeded 200 Gm. in 80 per cent of the cases. The lowest prescribed diet was 133 Gm. to a 6 year old, the highest 264 to an 11 year old child. Desugarization was accomplished in all without undernutrition, with a slight increase of average carbohydrate and an almost unchanged average dose of insulin. Accuracy of regimen, because of the lack of opportunity for dietary indiscretions, and timed exercise were great aids in therapy. A few children required supplementary doses of regular insulin at noon or in the late afternoon. This was occasionally administered to twenty-two children, or 14 per cent, in the second week.

The purpose of the camp as an adjunct to the treatment of juvenile diabetes is only partly recreational but designed largely to serve the child by permitting a period of adjustment and training in an environment normal for the age, to give relaxation for worried and tired parents and to reduce the cost of medical care. The Clara Barton Homestead Camp ran ten weeks. It could have provided 180 different campers a two weeks period of treatment, but special health, economic and behavior problems reduced the number to 128 and prolonged their stay. The cost was approximately $5,000, of which the Women's Missionary Association of the Universalist Church paid by far the greatest amount,

TABLE 2.—*Control of Diabetes in 123 Girl Campers on the Second, Tenth and Twelfth Camp Days, Measured by the Ratio of Dextrose Output to Carbohydrate Intake*

Day of Observation	Number of Girls	Perfect, per Cent	Excellent, per Cent	Good, per Cent	Poor, per Cent
Second	123	14	32	25	29
Tenth	110	25	49	20	6
Twelfth	107	32	47	17	4

approximately $2,500 in addition to providing the plant, which represents a valuation of perhaps $20,000, the Fund for the Study and Care of Diabetes from the George F. Baker Clinic $1,500, and the children $1,000. This camp unit is one of six where some 250 of our children received treatment with similar results during the summer of 1938. The medical staff includes a head nurse, an assistant nurse, a dietitian, a laboratory technician, play supervisors, a housemother, but no physician on the grounds. Diets are weighed, charts of the hospital type are kept, the amount of sugar excreted in twenty-four hours is determined daily by the Sheftel method, and capillary blood sugars are done by the Folin method.

We believe that protamine zinc insulin was successful in the treatment of these 123 diabetic girls, controlling hyperglycemia and glycosuria even when diets liberal in calories and carbohydrates were prescribed. Reactions of moderate severity occurred in 15 per cent. Minor fluctuations of glycosuria occurred. In most instances protamine zinc insulin was supplemented by a simultaneous and smaller dose of regular insulin always before breakfast. In our opinion, camps provide a routine life normal for children and are desirable and almost necessary for the medical management of young diabetic patients in moderate circumstances.

THE MALE CLIMACTERIC

AUGUST A. WERNER, M.D.
Assistant Professor of Internal Medicine, St. Louis University School of Medicine
ST. LOUIS

It seems reasonable to believe that many if not all men pass through a climacteric period somewhat similar to that of women, usually in a less severe but perhaps more prolonged form. The cessation of menstruation in the female at the so-called change of life has been tangible evidence for ages that the woman is having a decline in her sex function and is approaching the end of her child-bearing period. This cessation of menstruation in the female, usually called the menopause, is not the climacteric but represents only visible evidence that the woman is having endocrine imbalance. The endocrine dysfunction, plus the imbalance of equilibrium between the two divisions of the autonomic nervous system, with evidence at times of disturbance in the psychic centers, is the climacteric. The true climacteric is due primarily to decline of function of the sex glands. Decline of sex function is not limited to women but is also a heritage of all men. With the decline of gonadal function in the male there is a decrease of potency and libido. However, since libido has more of a mental and psychic basis and is to a great extent volitional, this factor may be affected to a less extent. In many instances the loss of potency and the persistence of libido causes many men to consult the physician.

The onset of decline of sex function in men is usually later than in women. The average age of onset for women is about 40.8 years and for men approximately 48 to 52 years. Probably a greater number of men than women pass through the climacteric without evident disturbance. Again, because of the prevalent belief that men do not have a climacteric period (which has been based on cessation of menstruation in women) the condition has probably been overlooked or ignored in men. Cessation of menstruation does not necessarily imply complete loss of libido in all women; neither does decrease of gonadal activity or the climacteric in men eventuate in total loss of potency, and certainly not of libido. That some few men are capable of fertilization (production of viable spermatozoa) to the advanced age of 80 years and beyond is an accepted fact, but this does not militate against the evidence that many men show beginning decline of potency at about 50 years of age, and during this period in life they have the typical climacteric syndrome which is mitigated by treatment with male sex hormones.

To refresh the memory, the symptoms complained of by 197 women (fifty-three castrates, ninety-six meno-

pause and forty-eight involutional melancholia patients) having deficiency or absence of the ovarian follicular hormone are presented in tabular form.

The climacteric symptoms in men may be classified as in women as nervous, circulatory and general in distribution. Among the more prominent symptoms may be mentioned intense subjective nervousness, definite emotional instability characterized by irritability, sudden changes in mood, decreased memory and ability for mental concentration, decreased interest in the usual activities, a desire to be left alone, and depression and crying. They may have hot flushes, which may be accompanied by profuse perspiration or be followed by a chilly sensation. There may be tachycardia and palpitation even while lying in bed and tachycardia, palpitation and dyspnea on moderate effort, vertigo

Order of Frequency of Symptoms Complained of in 197 Cases

Order of Frequency of Symptoms	Per Cent
1. Menstrual disturbances	99.2
2. Nervousness, subjective	97.6
3. Hot flushes	89.0
4. Excitability	85.7
5. Fatigability and lassitude	83.7
6. Depression and crying	77.4
7. Constipation	76.2
8. Irritability	75.1
9. Tachycardia, palpitation and dyspnea	68.8
10. Vertigo	67.4
11. Decreased memory and concentration	66.8
12. Sleep disturbed	66.1
13. Amenorrhea	57.6
14. Headache	56.4
15. Psychosis	52.2
16. Occipitocervical aching	50.6
17. Scotomas	49.4
18. Numbness and tingling	48.3
19. Cold hands and feet	35.3
20. Formication	25.4
21. Vague pains (recorded for involutional melancholia)	77.1

with or without change of position, scotomas, tinnitus, numbness and tingling of the extremities, fatigability and disturbed sleep.

The neurocirculatory symptoms such as hot flushes and suddenly increased perspiration, chilly sensations, vertigo, scotomas, tachycardia and palpitation, and numbness and tingling occur irregularly; they may be of frequent occurrence for a few days and then there may be a short period of relative freedom, only to recur.

The symptoms which are mental and psychic, such as irritability, changes in mood, decreased memory and concentration, loss of interest, restlessness and depression and crying, are usually more constant.

The climacteric disturbance may be so severe in some men that they become despondent and develop a psychosis with thoughts of self destruction. It is very probable that many men have committed suicide and no one could understand the reason for their having done so. That men have involutional melancholia can be confirmed by psychiatrists, for most institutions caring for mental cases have had these patients.

Recently Miller, Hubert and Hamilton [1] reported treatment of six male patients with testosterone propionate; two were adult castrates, two had hypogonadism and two apparently had psychic impotence. The doses varied from 20 mg. daily to three times weekly and were carefully controlled by injections of appropriate series of the oily solvent only. In addition to markedly diminished sexual libido and inadequate penile erections, these patients, prior to treatment with testosterone propionate were disturbed, anxious and broken in spirit. They ranged from moderate to severe states of mental depression. The four definitely organic cases displayed additional symptoms. These patients suffered from vasomotor disturbances (hot flushes), such as women may experience at the menopause, and manifested very definite emotional instability characterized by sudden uncontrollable shifts in mood, by tendencies to break down into tears, by periods of extreme irritability and sometimes by sullen anger. They also exhibited moderate to extreme degrees of both physical and mental fatigability. They complained of difficulties in concentration and of general apathy. Adequate treatment with testosterone propionate was causally associated with remarkable clinical improvement characterized by a marked increase in the erectile capacity and sensitivity of the penis, in the strength of the sex urge and in the capacity to respond with the proper emotions not only to intercourse but also to other acts such as kissing or embracing. During adequate treatment the two castrates appeared restored to normal in these respects. Also normal sex function and motivation were accompanied by great changes in the entire mental attitude of all patients. Their previous despondency gave way to definite elation, which in one psychogenic case (E) tended to wear off. All patients were less broken in spirit and were more spontaneous in their interests and activity. It is particularly interesting to note that additional changes occurred in the organic cases which were not observed in those without demonstrable hormonal abnormalities. The symptoms listed as peculiar to the organic cases were alleviated. They exhibited more rational aggressiveness and less irrational irritability and sullen brooding. Nervousness and emotional instability were replaced by greater stability and control. Abnormal physical and mental fatigability disappeared. Energy and stamina returned.

REPORT OF CASES

The following patient was in the male climacteric when he consulted me:

Case 1.—*History.*—W. K., aged 50, married, whose weight had been stationary at 160 pounds (73 Kg.) for five years, had always had good health and been successful, and his social contact had been normal. He had been subjectively nervous for several years, which condition had become worse during the last three or four years. For seven or eight years he had been aware of being excitable and irritable and lately he had been mentally depressed and had cried many times for no good reason. He had noticed hot flushes occasionally for about eight years; these occurred two or three times a month and might last one hour. During the past three years he had had a numbness and tingling of the extremities even while lying in bed, tachycardia, palpitation and dyspnea more than usual on moderate effort, easy fatigability, frequent scotomas and vertigo occasionally with occipitocervical aching and frontal headaches six or seven times a month, which might last from twenty-four to thirty-six hours. During the past two years he had had decreased memory and ability for mental concentration, and when this was accompanied by the occipitocervical aching his mind seemed hazy and fogged. He was fatigued most of the time and had lost interest in things. He slept poorly and lay awake from one to three hours each night.

He had measles and pertussis in childhood. In 1930 his appendix was removed but he stated that it was normal and that he did not get relief from the operation. A hydrocele was operated on two years before.

He had been married three times and had no children. The family history was negative as regards the patient.

1. Miller, N. E.; Hubert, Gilbert, and Hamilton, J. B.: Mental and Behavior Changes Following Male Hormone Treatment of Adult Castration, Hypogonadism and Psychic Impotence, Proc. Soc. Exper. Biol. & Med. **38**: 538-540 (May) 1938.

Examination.—His temperature was 98 F. at noon. His height was 67 inches (170 cm.) and his weight 153½ pounds (70 Kg.). His upper and lower measurements and one half span were equal at 36 inches. The genitals were normal. There were no abnormal physical signs. The pulse rate was 84 and the blood pressure 140 systolic, 100 diastolic.

The hemoglobin was 106 per cent (Sahli). The red cells numbered 5,380,000 and the white cells 8,700. There were no abnormal blood cells.

Urinalysis revealed neutral reaction, normal albumin and sugar tests and microscopically an occasional leukocyte but no casts.

The basal metabolic rate (two tests) was minus 2.5 per cent and minus 4.5 per cent.

The fluoroscopic examination of the chest, the heart, the stomach and the colon gave negative results.

The diagnosis was male climacteric.

Treatment and Results.—One cc. of testosterone propionate (perandren [2]) 10 mg. in oil was injected intramuscularly three times a week. After four weeks of treatment his subjective symptoms had markedly improved and he remarked that the depressed feeling was gone and he felt cheerful. He was treated for three months and his symptoms disappeared. After he had discontinued treatment for three months the symptoms began to return.

The following patient is a partial castrate with atrophy of the remaining testicle:

CASE 2.—*History.*—W. C. H., aged 42, married, stated that his sexual development was normal except for a left inguinal hernia, which was operated on in 1913. This was almost immediately followed by a hydrocele on that side. The hydrocele was then operated on and the left testicle atrophied. In 1927 a right herniotomy was done and the surgeon removed the left testicle because it was atrophied. The hernia on the right side recurred and he was again operated on for this. The day following the last operation the testicle was greatly swollen and painful, and since then he had lost the function of this gland.

For six weeks following the last operation he had decline of sexual potency to complete loss. He had sexual desire but had no erection for several months until he was treated, as will be described. With this loss of testicular function he became intensely nervous subjectively and had hot flushes almost every hour, which were accompanied by profuse perspiration. He was depressed and cried frequently for no reason. His memory and ability for mental concentration were decreased. He was restless and was ill at ease and worried. During the past three months he had had fatigability and a dull frontal headache each afternoon, which persisted until after he retired.

He was married and had a grown son and daughter.

Examination.—His height was 69 inches (175 cm.) and his weight 183 pounds (83 Kg.). His pulse rate was 76 per minute and the blood pressure was 130/80. The patient appeared to be ten years older than his age. There were no abnormal physical signs except the genital condition. The left testicle was absent; the right testicle was moderately decreased in size and its consistency was very hard. The epididymis was shrunken, hard and sclerosed.

The blood and urine were normal.

The diagnosis was castrate, left side; testicular atrophy, right side.

Treatment and Result.—The patient was given injections of testosterone propionate (perandren) 10 mg. in oil intramuscularly three times a week during the first month, twice a week the second month and once a week the third month. After the third injection he had an erection and coitus with an orgasm. He had not had an erection for nine months previous to this time. On a dosage of three injections a week during the first month he had three to four erections each week.

During the second month on a 10 mg. dose twice a week the erections occurred only once a week. During the third month on a 10 mg. dose once a week he had no more erections.

During the first month of treatment, on a dosage of 10 mg. three times a week, all his subjective symptoms disappeared. It requires three injections weekly to maintain him at normal. After the third month he discontinued treatment and quickly reverted to his original condition, both physically and subjectively.

2. Mr. Robert C. Mautner and the Ciba Company, Summit, N. J., supplied the testosterone propionate used.

COMMENT

Patient 1 had the symptoms complained of by women in the climacteric. These symptoms were relieved by injections of testosterone propionate and his interest in normal activities returned.

Patient 2 is a unilateral castrate with atrophy of the remaining testicle following a herniotomy. He had the same symptoms that are complained of by female castrates, with loss of sex function. His subjective symptoms were relieved, a cheerful attitude returned and the function of the erectile tissue of the genitals was restored as long as he received adequate doses of testosterone propionate.

CONCLUSIONS

1. It is evident that (some) men develop a typical climacteric syndrome at about the age of 50. It is reasonable to believe that with decline of gonadal function this should occur in men.

2. Testosterone propionate relieved the subjective symptoms in two male patients and restored the function of erectile tissue in the male sex organs of a castrate.

THE INFLUENCE OF MALARIAL INFECTIONS ON THE WASSERMANN AND KAHN REACTIONS

S. F. KITCHEN, M.D.
TALLAHASSEE, FLA.
E. L. WEBB
ATLANTA, GA.
AND
W. H. KUPPER, M.D.
CHATTAHOOCHEE, FLA.

Many contradictory opinions and results regarding the ability of malaria to provoke nonspecific, positive reactions with both the complement fixation and the flocculation test for syphilis have found their way into the literature. Lloyd and Mitra [1] summarized the reports on the question of falsely positive reactions which had been published up to the time they wrote, and they added data on eighty-five cases of their own. They believe that there is no evidence that malaria causes positive serologic reactions with modern technics. In a subsequent publication the senior author [2] of the former paper expressed the opinion that "the occurrence of positive reactions in malaria is partly a question of technic and partly a question of concomitant syphilis . . . *it is only with very sensitive technics* that a positive Wassermann will be obtained in malaria and even then the reaction is weak . . ." Kolmer [3]

Drs. Mark F. Boyd and T. B. Turner gave helpful suggestions and criticism during the prosecution of this study.

From the Station for Malaria Research, Tallahassee, Fla. (Dr. Kitchen); the laboratory of the Georgia State Department of Health, Atlanta, Ga. (E. L. Webb) and the Florida State Hospital, Chattahoochee, Fla. (Dr. Kupper).

The studies and observations on which this paper is based were conducted with the support and under the auspices of the International Health Division of the Rockefeller Foundation, in cooperation with the Florida State Board of Health and the Florida State Hospital.

stated that in his experience malaria, among other infections, had no influence per se on the Wassermann reaction, although the serums in acute febrile diseases might become somewhat more anticomplementary than usual. In a subsequent paper he [4] reported uniformly negative reactions in nonsyphilitic patients with tertian and estivo-autumnal malaria and stated "I am of the firm belief that the serums of nonsyphilitic malarial patients do not yield falsely positive reactions with my new method, even when the blood is drawn just before, during or after a paroxysm of chills and fever." Of interest in this connection are the results of an extensive study [5] conducted under the sponsorship of the United States Public Health Service. Specimens of serums

from nonsyphilitic persons with malaria or other diseases were distributed to a number of serologists who performed Wassermann or Kahn tests. Kolmer's laboratory reported positive Wassermann reactions for 19.4 per cent of the specimens obtained from patients with malaria. In the four laboratories in which these complement fixation tests were done the percentage of positive results for the malaria patients ranged from 8.6 to 20.6. Hazen and his associates [6] obtained positive results in 8 per cent of tests on 266 patients with malaria, presumably nonsyphilitic, and noted a higher proportion of positive reactions among females, particularly among those under the age of 10 years and from 60 to 69 years of age.

Other authors, namely Taussig and Orgel,[7] who cite the nonspecific results of a number of observers as varying from 4.9 to 80 per cent, Curth,[8] and Wilson and Levin,[9] who report one instance of a positive complement fixation on the cerebrospinal fluid in malaria, have also found various proportions of falsely positive reactions from malarial blood. On the other hand, Needles,[10] Menk,[11] Greer [12] and Heinemann [13] had the opposite experience. Saunders and Turner [14] also concluded that malaria does not cause fixation of complement with the method they used but that it might act as a provocative agent to raise a low titer reagin to the complement fixation threshold.

The present study was undertaken in an attempt to clarify this confusing situation by a new approach utilizing the opportunity presented by a decision to administer malaria therapy to a group of nonsyphilitic patients with functional psychoses. This permitted the systematic observations to be described and provided a restricted, although small, population.

The patients included in the study were divided into two series, in both of which there were persons who had malaria and nonmalarial controls. Table 1 presents pertinent data on all the patients. In all but two instances the histories of the patients, when obtainable, were negative for previous syphilitic infection. Two patients (270 and 1147) stated that they had had genital lesions that had not been treated. Physical examination failed to reveal evidence of syphilis in any of the patients. Moreover, routine serologic examination of the blood and spinal fluid made on all of them on admission to the hospital had given negative results.

FIRST SERIES

The first study group was composed of twenty persons. Nine of these were inoculated with Plasmodium vivax, two with Plasmodium falciparum and the remaining nine with the two species simultaneously. All inoculations were made with infected mosquitoes between May 5 and June 21, 1937. Specimens of serum to serve as controls were withdrawn from each patient prior to the first recognition of parasites in the peripheral blood; from two to four samples of serum were secured from each before inoculation. Subsequent specimens were taken at semiweekly intervals throughout the course of the malarial attack and until the results were negative. The Wassermann tests and some of the Kahn tests were performed by Mr. R. E. Morgan in the laboratory of the Florida State Hospital; the remaining Kahn tests were done in the branch laboratory of the State Board of Health at Tallahassee through the cooperation of Miss Estelle Bryan. The antigen used in this series of Wassermann tests was an

alcoholic extract of beef heart fortified with 0.4 per cent cholesterol as furnished by Mulford Colloid Laboratories. The complement was titrated prior to performance of the test. A preliminary incubation period of thirty minutes at 37 C. before the addition of the hemolytic system was followed by one hour's incubation at 37 C. In the case of the Kahn tests the standard antigen was employed. In the tests performed at the hospital the standard Kahn antigen used was that supplied by the Digestive Ferments Company. The central laboratory of the Florida State Board of Health prepares its own antigen, which is standardized in Kahn's laboratory.

SECOND SERIES

The second group comprised ten inoculated persons and one uninoculated control. In the control (case 285 of the first series), clinical malaria had failed to develop following inoculation. Five of these patients were inoculated with P. falciparum and five with P. vivax. Two of the vivax inoculations were unsuccessful. One of the patients inoculated with P. falciparum (313-1151) was reinoculated with P. vivax while convalescing from a falciparum infection. This patient's clinical experience, therefore, has been classified statistically as two separate attacks, one of falciparum and one of vivax, making a total of nine infections in series 2. As in the previous series, these patients were all inoculated with infected mosquitoes, the inoculations taking place between Nov. 19 and Nov. 23, 1937. The serologic tests in this group were carried out in the laboratories of the Georgia State Board of Health, Atlanta, through the collaboration of Dr. T. F. Sellers, director, and differed from the previous run in that the presumptive Kahn test was done in addition to the Wassermann and standard Kahn tests. The Kahn tests in this series were performed as outlined by Dr. Kahn, and the antigens used were standardized in his laboratory. The complement fixation technic employed was a three tube Kolmer modification in which 10 units of the latter's cholesterolized antigen was used. Two full units of guinea pig complement was used, and both amboceptor and complement were titrated prior to use. Primary incubation was carried out for from fourteen to eighteen hours at 6 to 8 C. followed by from ten to fifteen minutes at 37 C. The hemolytic system was then added, and incubation at 37 C. was continued until ten minutes after the negative controls showed complete hemolysis.

Prior to inoculation, from five to eleven specimens of serum were obtained from each patient in this series. Following inoculation, specimens were collected at semiweekly intervals until three completely negative results were reported for each patient.

In addition to these tests a duplicate specimen of serum from each of two patients (304 and 1147) in series 2 was frozen and stored at about —7 C. in a freezing chamber each time blood was taken from these persons for cufrent examination. The specimens were finally sent to the laboratory in the frozen state and tested simultaneously.

RESULTS

It will be noted in table 1 that double infections developed in only two (271-1126 and 277-1128) of the nine doubly inoculated patients in series 1. The nature of these infections has been described in another publication.[15] Three of the nine experienced vivax attacks

* W = Wassermann, K = Kahn, PK = Presumptive Kahn, SK = Standard Kahn.

alone, which together with the six other successful vivax inoculations in this series provided nine infections with that species. In the remaining four doubly inoculated persons the infections were predominantly falciparum, bringing the total of falciparum attacks up to five. In series 2, patient 313-1151 was inoculated successively with P. falciparum and P. vivax, and there were in addition three single vivax and four falciparum infections.

In four persons (285, 287, 288 and 1136) in the first series clinical malaria failed to develop, and no malarial parasites were observed in their blood at any time. Of these, one (288) showed four positive Wassermann reactions. Another (1136) exhibited two positive Wassermann reactions, one anticomplementary specimen and one positive Kahn reaction. In case 288, an elevation of the temperature to 38.3 C. (100.9 F.) was observed two days after the first positive serologic reaction. No possible explanation other than a hookworm infection was discoverable. The other person (1136) experienced no elevation of temperature, but a diagnosis of tubo-ovarian disease had been made. While these conditions may have had no significance, they were the only infections found in the two persons exhibiting positive serologic reactions.

Positive serologic reactions with each type of test.- Solid line, Wassermann; broken line, presumptive Kahn; dots and dashes, standard Kahn.

In the second series were two persons (305 and 307) in whom malaria did not develop, and one uninoculated person (285 of the first series) was included to serve as a negative control. None of these three patients showed positive reactions or malarial parasites at any time during the period of observation. April 19, 1938, however, patient 285 experienced a rigor. Smears prepared from his peripheral blood on April 22, when he first came to the attention of the malaria therapy service, proved to contain P. vivax. The clinical course was pure tertian. It seems likely that this patient's infection resulted from his inoculation of June 21, 1937. This would mean an incubation period of more than ten lunar months, which is new in our experience. Wassermann, presumptive Kahn and standard Kahn tests were performed on his serum April 22. The complement fixation test was doubtful, but both of the Kahn reactions were strongly positive. These positive serologic reactions obtained from a person in whom malaria developed and who had had so many negative control reactions previously serve to corroborate our other observations.

As may be further noted in table 1, the incubation periods (terminated by the first recognition of parasites in thick blood films) observed for the twenty-five malarial infections ranged from nine to sixteen days. In fifteen cases it was eleven days. In nine each of the vivax and falciparum cases it fell within the first twelve days. The initial fever was observed to occur on the tenth to the twentieth day after inoculation, with the greatest incidence on the twelfth day (eight cases).

In table 2 are presented the number of positive and negative serologic results observed in each case. These results are further classified according to the type of test and in relation to the stages of the malarial infection. The four divisions selected for the latter purpose are, as will be seen in the table, (1) before inoculation, (2) during the incubation period, (3) during the malarial attack (terminated by the final paroxysm or elevation of the temperature to at least 37.8 C. and (4) after the malarial attack. It should be remarked that the results in case 313-1151 in series 2 have been listed separately for each infection, namely those for the falciparum infection under case 1151 and those for the succeeding vivax attack under case 313. The second attack in this instance followed so closely on the first that it was not possible to present complete data for it in the table. The results obtained for the persons who were not inoculated or in whom malaria did not develop are placed for convenience under the column headings "before inoculation" or "during incubation period."

It will be observed that in each of the twenty-five attacks in both series positive serologic reactions were obtained on at least two occasions at some time during the course of the malarial infection.

It will also be noted that no specimen obtained prior to the time of inoculation yielded a positive result; thus the observations made on admission in all the cases were substantiated. During the incubation period, as table 2 further shows, each of two patients (278 and 1130) exhibited one positive reaction. In the former case the Kahn reaction was positive twelve days after inoculation, although it was not until four days later that parasites were first observed. Between the first and subsequent positive reactions, a period of fourteen days, three negative Wassermann and five negative Kahn reactions were obtained. In case 1130 the first positive Wassermann was noted five days after inoculation and five days prior to the first appearance of parasites. This result, however, was followed by five consecutive positive reactions to the complement fixation test. In addition to these two patients, one other (268) showed one doubtful Wassermann reaction ten days after inoculation and one day before the first detection of parasites. The four subsequent Wassermann reactions in this instance were positive.

It is apparent that considerable variation existed among these cases with reference to the incidence of positive reactions as well as in the distribution of the latter in relation to the stage of the malarial infection. In series 1 there were two patients (1127 and 277-1128) who at no time throughout the course of the infection gave a positive Kahn reaction. One of these (1127), however, did give 100 per cent positive Wassermann

reactions during the attack. There was no instance of 100 per cent negative Wassermann reactions in this series. In series 2 there were two persons (308 and 1149) who failed to exhibit a single positive Wassermann reaction but none showing totally negative Kahn reactions.

As may be seen in table 2, there were in all four persons (276, 277-1128, 304 and 1147) who failed to show positive serologic reactions prior to the conclusions of the malarial attack. In two of these (277-1128 and 304) it had been necessary to terminate the attack because of the development of an intercurrent infection. The clinical duration of the plasmodial infection in the other two had been relatively short (twelve days in case 276 and eight days in case 1147).

In nineteen of the twenty-five attacks studied, the first positive reactions were encountered some time during the febrile phase of the disease. The first positive reactions varied, however, in their time of appearance from the day of onset to seventeen days after the initiation of clinical activity. It may be determined from table 1 that in seventeen of the nineteen, or 68 per cent of all twenty-five infections, initial positive reactions were exhibited during the first two weeks of the paroxysmal stage.

Referring again to table 1, it is seen that there was considerable difference in the length of the interval between inoculation and the appearance of the first serologic reaction among the persons in the first series and less variation among those of the second series. Nevertheless the average duration of this "seronegative" period was twenty and 22.8 days, respectively, in the two groups. Seventy-two per cent of the positive reactions in the twenty-five persons experiencing attacks of malaria made their first appearance during the third and fourth weeks after inoculation. It is noticeable that our patients, having reached the "seropositive" state, marked by the appearance of the first positive test, showed a wide divergence in the duration of the interval from the first to the last positive serologic reaction. This period varied from eight to sixty-six days in duration, the average length being twenty-nine days. It was less than three weeks in 40 per cent of the attacks, more than three weeks in 60 per cent, more than four weeks in about half and more than five weeks in 32 per cent.

It may be remarked here that there was a considerable degree of irregularity in the serologic positivity among these infections during the "seropositive" period. In all, only fourteen persons showed consistently positive results from the first to the last positive reaction with one or more tests. Six patients of the first series exhibited consistency with the Wassermann reaction and one of these with the standard Kahn as well. In the second group, eight patients showed regularity in serologic positivity with the complement fixation (three cases), presumptive Kahn (six cases) and standard Kahn tests (four cases). The remaining patients of the two series presented doubtful and negative results interspersed among the positive reactions. In some of the latter cases the appearance of intervening negative or doubtful results appeared to be associated with a brief subsidence of the paroxysms, which frequently occurs in the course of the clinical attack, but in the majority of the serologic irregularities no such relationship was demonstrable. Alterations in the parasite density were considered as a potential factor, but here again the association was not constant. In many instances no possible cause, and certainly no constant factor, was apparent.

With further reference to the period from the first to the last positive serologic reaction there were observed during that time, in all, 320 positive and 307 negative reactions. These positive and negative reactions were considered in relation to the duration of clinical activity in the twenty-five cases, which was divided into that of twenty-eight days or less and that of more than twenty-eight days. In this way a four square table was constructed for each type of test. It was found that the positive results from the Wassermann test alone increased significantly (chi square, 9.9) with prolonged clinical activity.

In some instances the paroxysms terminated before the patient became seronegative, while in other instances the patients became seronegative before the termination of the paroxysms. These contradictory occurrences were divided about equally, although in a few cases the administration of quinine had apparently shortened the clinical course.

Table 3, which was prepared to supplement the data given in table 2, shows the total percentage of positive results obtained with each type of test during the different stages of the infection. The accompanying chart presents the same data in graphic form, combining the results obtained in the two groups. It is apparent that in both series the greatest proportion of positive reactions from each test occurred during the second two weeks of clinical activity. In the first series the second greatest proportion occurred during the first two weeks and in the second series during the third two weeks of

* W = Wassermann, PK = Presumptive Kahn, SK = Standard Kahn.

that stage of the infection. The increase in the percentage of positive reactions noted during the first two weeks following the active phase of the disease is no doubt due in part to the patients who did not exhibit positive serologic reactions until after the paroxysms ceased.

The chronologic relation of each positive serum reaction (all tests) to the nearest paroxysm has been determined and presented in table 5. Each serologic result was classified according to (1) the number of days by which it preceded the first paroxysm of the attack, (2) whether it occurred on the same day as a paroxysm or (3) the number of days by which it followed the immediately preceding paroxysm. The results of this classification were then divided into seven day intervals. The percentage of positive reactions for each group is recorded. It will be noted that during the week preceding the clinical onset the positive specimens formed only 5.1 per cent of those collected in that period, while in the case of the specimens obtained on the same day as a paroxysm the incidence of positive reactions rose to 35.5 per cent. During the days subsequent to the last previous paroxysm this proportion continued to rise until a maximum of 52 per cent positive specimens were collected during the third week. After the third week the positive results fell rather rapidly to the low point of 8.3 per cent, observed during the sixth and seventh weeks.

The proportion of positive serologic reactions in these persons was studied for possible correlation with the species of plasmodium involved and the sex and age of the patients; the results are shown in table 4. This revealed that during the attack the cases of vivax infections exhibited the greater percentage of positive reactions with the Wassermann and standard Kahn tests; but with the presumptive Kahn test the greater proportion of positive reactions was found in the falciparum cases. Following the malarial attack, the falciparum infections contributed the larger percentage of positive Wassermann reactions, whereas the positive reactions with the two Kahn tests were found in relatively greater numbers among the attacks due to P. vivax. Of all specimens obtained from persons with vivax infections, 28.1 per cent gave positive reactions, while such reactions were exhibited by 20.4 per cent of all specimens secured from falciparum-infected patients.

It will also be noted in table 4 that the males contributed the greater proportion of positive Wassermann reactions during the attack but that the females exhibited relatively more positive Kahn reactions as well as total positive reactions. Following cessation of the attack, the males showed a greater percentage of positive Wassermann reactions and of total positive reactions. Of all specimens of serum secured from males, 22.7 per cent gave positive reactions whereas of those from females 28.7 gave positive reactions. It is apparent that the lower age group (those up to 35 years) consistently exhibited proportionately more positive results both during and after the attack. The same group showed 26.8 per cent positive reactions among the total tests on their serums, as against 18.3 per cent of positive reactions for the group whose ages exceeded 35.

All positive serologic reactions obtained with each of the three tests were considered in relation to the duration of the clinical attack of malaria. For this purpose the latter were divided into two groups, namely those lasting twenty-eight days or less and those lasting more than twenty-eight days. It was found that only in the case of the Wassermann test did the incidence of positive reactions vary directly to a significant degree (chi square, 13) with the clinical duration of the attack.

The cerebrospinal fluid was examined in four cases during the active phase of the malarial attack. One of these (271-1126, on the fifteenth day of the disease) showed a strongly positive Wassermann reaction, a normal colloidal gold reaction and a leukocyte count of 28 per cubic millimeter. Prior to the induction of malarial therapy the serologic reaction of this patient's cerebrospinal fluid had been completely negative (5 leukocytes per cubic millimeter). Unfortunately a specimen was not obtained following recovery because of the patient's unexpectedly early parole from the institution.

In comparing the results obtained on the frozen duplicate serums simultaneously examined from patients 304 and 1147 with those on the unfrozen specimens currently examined, some differences were noted. In case 304 the unfrozen specimens showed positive presumptive Kahn reactions considerably longer than the frozen ones, but one of the latter provided the only positive Wassermann reaction obtained from that individual. The serum of the other patient (1147) yielded fewer positive presumptive Kahn reactions in the case of the frozen specimens, but otherwise the difference was not marked.

COMMENT

That malarial infections may influence, even profoundly, the reaction of the serologic tests for syphilis can scarcely be doubted. The systematic observations

on the Kahn and Wassermann tests as carried out on our series of nonsyphilitic patients showed that all in whom a clinical attack of malaria developed exhibited positive results at some time during the course of the infection. That such results ought to be attributed to coincident syphilis, as suggested by some authors, does not appear to be reasonable. The negative results obtained in our cases both prior and subsequent to the positive results, together with the absence of any clinical evidence of syphilis, would support our contention, and the range in sensitivity of the serologic reactions which obtained in this study appears to add weight to our positive results. It is realized that a positive reaction with the presumptive Kahn test does not necessarily mean the presence of a syphilitic infection; it is more sensitive than the standard test and serves as a check on the latter as well as to establish the absence of syphilis in the case of a negative result. Nevertheless it was felt that it would be of interest to include in this paper the results obtained with the presumptive test. One might have expected the Wassermann test as performed on specimens in series 2 to be more sensitive than as carried out in series 1. The results, however, did not indicate this.

In view of the results observed in the present study it seems quite probable that one factor contributing toward the conflicting results recorded in the literature may well be the stage of the infections at which the samples of serums were collected by various workers. Noteworthy in this connection is the irregularity in the time of appearance of the first positive serologic reaction observed in our cases and the interspersion of negative reactions among the positive.

It is possible that the maximum frequency of positive results noted during the third week following paroxysms (table 5) may have some significance with regard to the mechanism of falsely positive reactions. Similarly, the partial duplication of a paretic serologic reaction in a spinal fluid may have some significance in view of the therapeutic value of malaria in dementia paralytica. Our data do not offer any explanation of these obscure observations.

Perhaps the most important question brought out by these results is that of how much reliance to place on positive serologic reactions obtained in an endemically malarious area. In our opinion it is of greatest importance that malaria be ruled out before such positive results are accepted. Emphasis is lent to this by reason of the positive reactions observed for variable periods in a number of cases after the cessation of clinical activity. In all but one instance in which this occurred parasites were still detectable in the blood smears. In this one case an intercurrent nephritis had developed, and it cannot be determined from our data just how much influence this condition may have exerted even for some time after the termination of the malarial infection by means of quinine. It is not unlikely that a certain number of patients in malarious areas have been treated for syphilis on the basis of positive serologic reactions alone, when the latter were in fact due to malarial infection.

SUMMARY

A systematic study of the Wassermann and Kahn reactions was made before, during and after twenty-five naturally induced attacks of malaria in nonsyphilitic patients. Positive reactions were obtained in every case in which malaria developed clinically. Two cases showed no positive results from the complement fixation tests and two others showed no positive Kahn reactions.

There was an instance of malaria provoking positive serologic reactions and a considerably increased cell count in the cerebrospinal fluid.

Seventy-two per cent of the positive reactions made their first appearance during the third and fourth weeks following inoculation. The first positive reactions were observed both before and after the period of clinical activity in a few instances, but in 68 per cent of the attacks they occurred within the first two weeks of the febrile period. The duration of the "seropositive" period exceeded three weeks in 60 per cent of the cases and extended beyond four weeks in 48 per cent. During this time 320 positive and 307 negative serologic reactions were obtained.

When the results from all tests were totaled, there was observed a tendency for vivax infections to induce a greater proportion of positive serologic results than falciparum infections. Likewise the relative number of positive reactions was higher among females with malaria than among males, and among persons up to 35 years of age than among those over that age.

The percentage of positive reactions was highest during the period from fifteen to twenty-one days after the last previous paroxysm.

COMPLEMENT AND ASCORBIC ACID IN HUMAN SCURVY

AN EXPERIMENTAL STUDY

E. E. ECKER, PH.D.
LOUIS PILLEMER, PH.D.
WITH THE ASSISTANCE OF
J. J. GRIFFITTS, M.D.
AND
W. P. SCHWARTZ, M.D.
CLEVELAND

Ecker, Pillemer, Wertheimer and Gradis [1] showed that a correlation exists between the concentration of ascorbic acid in the blood serum of guinea pigs and the complementary activity of the serum. These authors further demonstrated that, in vivo, the relationship holds true until a definite level of ascorbic acid is reached at about 1 mg. per hundred cubic centimeters of serum. It was also found that serums treated in vitro with optimal quantities of ascorbic acid improved in their complementary powers and showed greater stability.

From these observations the suggestion was finally made that the complementing activity of the serums of scorbutic guinea pigs and of men may be used as a biologic index of vitamin C deficiency.

Since these studies have appeared, Chu and Chow [2] independently also noted that a qualitative relationship exists between vitamin C intake and complement titer in human plasma. The authors stated that an adequate explanation of the phenomenon is not clear at present.

Chu and Chow studied two groups of subjects. The first group consisted of two children and one woman.

From the Institute of Pathology, Western Reserve University and University Hospitals, and Cleveland City Hospital.

1. Ecker, E. E.; Pillemer, L.; Wertheimer, D., and Gradis, H.: J. Immunol. 34: 19 (Jan.) 1938.

2. Chu, Fu-T'ang, and Chow, B. F.: Proc. Soc. Exper. Biol. & Med. 38: 679, 1938.

In this group simultaneous determinations of reduced vitamin C and complement were made over extended periods in which the vitamin C intake was raised or lowered by the addition of ascorbic acid to, or its withdrawal from, a constant basal diet. They noticed in all three cases that the use of ascorbic acid or of vegetables led to an increase of complementary function, while a withdrawal induced a decrease. In their second series, thirty-eight patients of different ages were studied. The patients suffered from a variety of diseases. The vitamin values were divided into three groups: deficiency, presaturation and saturation. A low vitamin C content was in the majority of cases accompanied by a low complement titer, while a high vitamin C value was associated with a high complement titer.

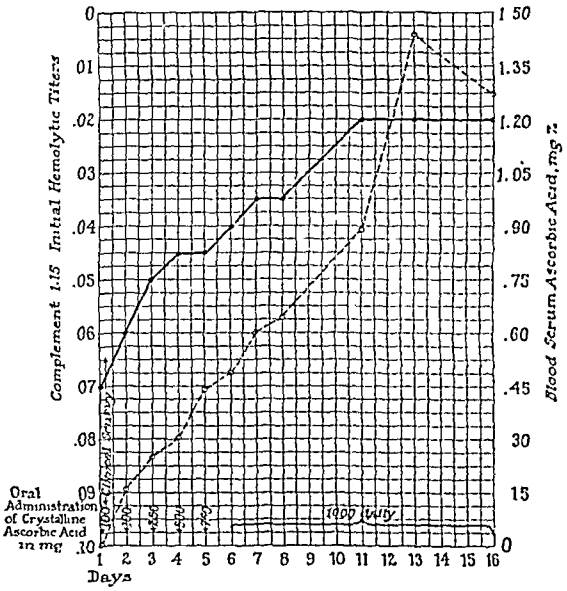

Chart 1.—*Demonstrating the correlation existing between ascorbic acid content of the serum of patient 1 and initial complement titers. In the charts the solid line indicates complement 1:15 serum dilution; broken line, blood ascorbic acid, mg. per hundred cubic centimeters.*

These observations substantiate the experimental studies of Ecker, Pillemer, Wertheimer and Gradis and establish a new relationship between these factors, which is obviously of clinical as well as of theoretical importance.

The present report is an experimental study of two cases of typical human scurvy. These cases corroborate the results obtained by us in cases of scurvy in guinea pigs and introduce a new biologic method for the determination of the point of saturation of vitamin C.

REPORT OF CASES AND ACCOMPANYING EXPERIMENTAL WORK

CASE 1.—*History.*—I. B., a white woman aged 36, admitted to Lakeside Hospital June 25, 1938, complained of a brownish vaginal discharge of about two weeks' duration. The patient had had one miscarriage and no further pregnancies. She had the usual childhood diseases without sequelae. Tonsillectomy was performed eleven years before. She stated that she had had a severe gingivitis eight or nine years before the present illness which responded to local therapy.

The patient was of the thin and nervous type and was subnormal mentally. For about twelve years she had suffered from pains in her back, hands and shoulders. She had frequent attacks of dysmenorrhea during that time and chronic constipation. Five years before admission she had diarrhea often initiated by emotional factors. Two years later constipation became so marked that she had no bowel movement without an enema. A year later a barium sulfate enema showed no abnormality of the colon, but even then the gums were dirty and of foul odor. Amenorrhea began a year later and continued until two months before admission. For the last seven months she had placed herself on a diet totally deficient in vegetables and fresh fruits. She noted that her gums were swollen and that they bled easily. One month before admission she noted a brownish vaginal discharge and red spots on her legs. About one week prior to her admission she had muscular soreness in the left thigh.

Examination.—The temperature was 37.4 C. (99.3 F.), pulse rate 100, respiratory rate 20 and blood pressure 102 systolic, 80 diastolic. The patient was thin, pale, underdeveloped and poorly nourished. There were no abnormalities of the eyes, ears, nose or throat. Her breath was foul and her gums were swollen, hanging down over the molars like thick curtains. They were a deep purplish red and bled readily on pressure. The chest was clear and the heart was normal as to size and rhythm. No murmurs were heard. There was some tenderness over the fourth, fifth and sixth ribs on the left. The abdomen was normal, as were the rectal and pelvic areas, except for a small amount of blood-stained discharge from the vagina. Over the anterior portion of the legs there were many small pinhead sized red lesions (macular), each of which appeared to be grouped about the hair follicles. The reflexes were normal. There was no evidence of subperiosteal hemorrhages.

Laboratory Results: Red blood cells numbered 3.85 million, hemoglobin content 74 per cent; white blood cells 8,000; the differential count was normal. Kline's exclusion test gave negative results. Blood urea nitrogen was 8.3 mg. per hundred cubic centimeters; nonprotein nitrogen 25.7 mg., creatinine 1

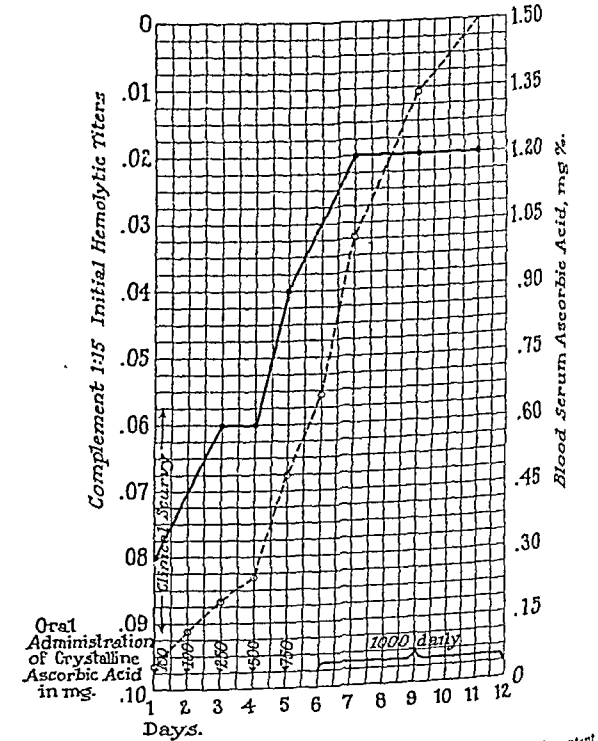

Chart 2.—*Demonstrating the correlation between ascorbic acid content of the serum of patient 2 and the initial complement titers.*

mg. Examination of the stool was negative. Bleeding time was 2.5 minutes, clotting time 2.5 minutes. Clot retraction was normal. The Rumpel-Leede test produced many petechiae after the cuff was applied for five minutes at a pressure of 90 mg. of mercury. Serum ascorbic acid was absent. There was no ascorbic acid in the urine. The electrocardiogram was normal and the circulation time was normal.

Course.—The patient was placed on a vitamin C-deficient diet and on her sixth day in the hospital she received 100 mg.

of crystalline ascorbic acid by mouth. The same dose was given on the second day. On the following four days she received respectively 250, 500, 750 and 1,000 mg. for a period of one week. Three days after the therapy was initiated the Rumpel-Leede test became negative. On the fifth day of the regimen her gums began to shrink and there was no bleeding on pressure. The vaginal discharge disappeared and the patient continued to improve.

During her hospital course the blood was examined daily. The ascorbic acid content of her serum was

* Solutions employed: 0 5 cc of 0 002 normal solution of potassium cyanide in 7.2 buffer solution M/15; 0 5 cc of hydrogen sulfide water (saturated) 20 per cent in buffer solution M/15; 0.15 mg. ascorbic acid in 0.5 cc. of 7.2 phosphate buffer M/15, and the same of glutathione SH.

immediately titrated with dichlor-phenolindophenol. At the same time the initial complement titer of the serum was estimated. On admission her initial complement titer was 0.07 cc. of a 1:15 dilution, a rather low figure. The strength of human complement is about one half of that of the guinea pig. The patient's weakened complement was also daily reactivated with ascorbic acid, glutathione SH, hydrogen sulfide and potassium cyanide. The method described by Ecker, Pillemer, Martiensen and Wertheimer [3] was followed. It has been shown by these workers that the weakened complement obtained from scorbutic guinea pigs can be reactivated by various reductants, such as hydrogen sulfide, ascorbic acid and sodium hydrosulfite. Normal complement was also reversibly inactivated by a variety of oxidizing agents, provided the inactivation was strictly controlled. The oxidizing agents employed were iodine, hydrogen peroxide, quinone and oxygen. The same also held true for cuprous oxide and phenylmercuric chloride. Complement inactivated by these agents was regenerated by the various reductants mentioned and by heat-inactivated complement and by complement lacking the third or the fourth component.

Chart 1 shows the results obtained following the gradual administration of crystalline ascorbic acid.

The curves clearly demonstrate the parallel rise of ascorbic acid and of complement. This rise continued until a concentration of about 1 mg. of ascorbic acid per hundred cubic centimeters of serum was reached. At this point the complement titer reached its maximum, while the concentration of ascorbic acid increased to a maximum of 1.44 mg. per hundred cubic centimeters. This finding corresponds to the phenomenon observed by Ecker and his associates in the case of the guinea pig.

Table 1 shows the figures obtained after the daily reactivations.

3. Ecker, E. E.; Pillemer, L.; Martiensen, E. W., and Wertheimer, D.: J. Biol. Chem. **123**: 351 (March) 1938.

This table shows conclusively that the weakened complement can be reactivated and that ascorbic acid showed the best reactivating qualities. However, glutathione SH, potassium cyanide and hydrogen sulfide all brought about reactivations. As the titer of the complement improved under the treatment with ascorbic acid, the reactivations became less marked until no further reactivation was possible.

These observations clearly indicate that the complement of the guinea pig and of man is controlled by oxidation and reduction and that the complement in cases of vitamin C deficiency occurs in a greatly oxidized state.

CASE 2.—*History.*—J. G., a man aged 59, a Hungarian, was well until July 5, 1938, one week before admission to the City Hospital, at which time he noticed swelling and bluish discoloration of his feet, ankles and legs. His diet had consisted chiefly of black coffee and cookies and an occasional "hamburger" during the past four months. The patient suffered from muscular tenderness and found walking painful.

Examination.—Physical examination showed emaciation, dryness of the skin and ill defined, confluent patches of subcutaneous hemorrhages over the dorsum of both feet, legs and lower thighs (posteriorly). Numerous perifollicular hemorrhages were observed on the lower part of the thighs and legs. There was definite tenderness of the muscles and tendons. About the nine carious teeth the gums appeared to be spongy and bled readily. No pus appeared about the margins of the gums. The patient did not complain of tenderness of the bones and joints. The Rumpel-Leede test gave a negative reaction, as well as the cupping test.

Laboratory Results: Bleeding time was 1.5 minutes and clotting time 6 minutes. Clot retraction occurred in thirteen hours. There was increased fragility of the erythrocytes. Red blood cells numbered 3.2 millions and the white blood cell count was normal. Examination of the urine was negative for blood but the stools gave a positive reaction.

Course.—The patient was placed on a vitamin C deficient diet and after two control bleedings were made he was given crystalline vitamin C by mouth. The doses given were the same as in the first case. The patient was bled daily and his serum ascorbic acid content and complement titer were determined. On July 19 his general condition was definitely

* The amounts of the reductants, etc., were given in the first table.

improved. July 21 he showed no muscular tenderness and his gait was practically normal. July 26 the hemorrhages on his lower extremities showed great improvement. The gums were still edematous but less red and bled only after considerable manipulation. The patient continued to improve.

The parallelism between his serum ascorbic acid content and complementary titers is given on chart 2. His initial complement titer on admission was 0.08 cc. of a 1:15 serum dilution and his ascorbic acid content about 0.06 mg. per hundred cubic centimeters. Following the oral administration of the vitamin a gradual rise of both factors occurred. When the ascorbic acid content reached a concentration of about 1 mg. per

hundred cubic centimeters of serum the initial complement titer reached its maximum at about 0.02 cc. of a 1:15 serum dilution. A further increase of the ascorbic acid content to 1.9 mg. per hundred cubic centimeters of serum did not increase the complementing power.

The curves in both cases are fundamentally identical except that in the second case the curves are steeper, indicating a more rapid response to the treatment.

Again, the serums secured from the daily bleedings were reactivated by the reductants already mentioned (table 2).

Ascorbic acid and glutathione SH showed the most marked reactivating effects.

COMMENT

These two cases conclusively demonstrate the relationship between complementary activity and the ascorbic acid content of the serums of scorbutic persons during the course of treatments.

Since the complementary activity can be carefully determined, it is proposed that this factor be studied in all cases of suspected vitamin C deficiencies, including the infections.

A low complementary titer will probably lower the general immunity of the patient. Experimentally, Moore [4] has shown this to be the case in a strain of complement-deficient guinea pigs. These animals were more highly susceptible to infections than comparable animals with a normal complement titer.

In the case of vitamin C deficiency, complementary activity has been conclusively shown to be important. Complement titration, therefore, becomes of value in all cases of clinical or subclinical scurvy and will also indicate the point of saturation in the course of treatments. According to Wright and Lilienfeld,[5] Harris and Ray [6] and Archer and Graham,[7] subclinical scurvy is very common. In a recent report Sloan [8] stated that the assay of a single sample of urine is a rough and frequently false measure of vitamin saturation. The Rumpel-Leede test is also not too reliable. This test was negative in the second case described in this paper. So far, the most dependable method is the determination of the rate of absorption of a dose of the vitamin injected into the blood stream. The determination of the complementary activity of the blood furnishes a biologic index of the amount of ascorbic acid present. It may well replace the quantitative chemical estimation of the ascorbic acid in those instances in which both methods cannot be utilized.

SUMMARY

Two patients with typical human scurvy were kept on a vitamin C free diet and treated orally with graded doses of crystalline vitamin C. The initial complement titers as well as the ascorbic acid content of the blood serums of the patients were determined daily. The original complement titers were very low, namely 0.07 and 0.08 cc. of a 1:15 serum dilution. The ascorbic acid contents of the serums were practically nontitrable. After the daily oral administration of crystalline vitamin C in graded doses the curves of vitamin C concentrations and complementary titers ran a practically parallel course until the weakened complement was completely restored by the ascorbic acid at a concentration of a little over 1 mg. per hundred cubic centimeters of serum. Additional doses of the ascorbic acid failed to raise the final initial complement titers, namely 0.02 cc. of a 1:15 serum dilution.

These observations conclusively confirm the original observations made by Ecker, Pillemer, Wertheimer and Gradis [1] in the guinea pig and the later observations of Chu and Chow [2] in man.

END RESULT OF A TUBERCULOSIS CASE FINDING PROJECT

J. B. NOVAK, M.D.
AND
J. S. KRUGLICK, M.D.
CHICAGO

To call this paper or any other paper the end result of a case finding project is really a mistake. The nature of the disease tuberculosis is such that no end result can be determined within the space of five, ten or even fifteen years. Hence our presentation, which is a three to five year follow-up, can hardly be termed an end result. There are, however, certain important facts that have been determined by this work and these we wish to present.

Prior to the advent of the x-ray and tuberculin test, physicians depended on contact history, subjective symptoms and physical examination for the diagnosis of tuberculosis. The objection to these methods was that the cases uncovered were almost invariably in an advanced stage and treatment was either prolonged or unsuccessful. With the perfection of the x-rays, suspected cases could be checked. This led to earlier diagnosis but it was still not conducive to group work. With the tuberculin test and increased knowledge of tuberculosis, physicians turned to group testing. The true purpose of this work is to discover disease in the incipient stage, when treatment is more successful.

In any case finding project, one can determine (using two or three tests) almost 100 per cent of those infected with tuberculosis. Large scale testing can be done at a relatively low cost. The positive reactors could be roentgenographed and tuberculous disease determined long before the patient shows subjective signs.

Lay education has progressed apace. Each year larger numbers accept these examinations. People are more and more beginning to understand the "apparent outward" significance of a positive reaction and the value of early diagnosis.

There is no question that these improved methods of case finding and progressing education have lowered the infection rate in tuberculosis and certainly the death rate has shown a steady drop. However, in our zeal to uncover new cases of this disease is it possible we have neglected those already discovered? This question is born of an investigation conducted by the Tuberculosis Institute of Chicago and Cook County.

From 1933 to 1936 we discovered some sixty-five cases of tuberculosis in the high school students of Chicago and its suburbs. Forty-five of these were diagnosed either suspected or incipient disease, nineteen as moderately advanced and one as far advanced. Each case

From the Tuberculosis Institute of Chicago and Cook County.

was reported and referred for treatment. Late in 1937 and early in 1938 a follow-up study was conducted to learn the status of these individuals. To say that the results were disappointing would be a gross understatement. They were astonishing. It was difficult to believe that for all our success in early diagnosis, improved methods and facilities for treatment, and progressive education the death rate and morbidity were so high, our control of these cases so poor, and the number of deaths greater in the incipient than in the advanced group.

Of the sixty-five patients seven had died (10.85 per cent) within three to five years. What is so paradoxically striking is that of the twenty patients with advanced tuberculosis one (5 per cent) has died, while of the forty-five patients in an early stage six (13.33 per cent) have died. Further, the remaining nineteen patients with advanced tuberculosis are holding their own but of the incipient group eight are now in an advanced stage, a total mortality or morbidity increase of fourteen cases, almost 33 per cent (table 1).

In the search for the reason for these disproportionate observations let us consider table 2.

Let us analyze these figures. Of the forty-five patients with the disease in the incipient stage twenty-two (49.11 per cent) had active treatment. The other twenty-three were put under observation. In the twenty advanced cases active treatment was given in nineteen (95 per cent). In the type of treatment it will be noted that in the incipient group the largest percentage of the twenty-two actively treated fall into the bed rest class, twelve or 54.54 per cent, and seven (31.81 per cent) into the pneumothorax class, while only three (13.63 per cent) had both. In the advanced group almost the opposite is noted; eight (42.10 per cent) fall into the class who had both bed rest and pneumothorax, six (31.57 per cent) had pneumothorax alone and four 21.05 per cent) had only bed rest. Complete bed rest was employed in the one phrenic case. We are not presenting these figures as an index of the relative values of different treatment but merely to show the more active measures used in the advanced cases.

Let us review briefly the seven deaths. One was a case diagnosed far advanced tuberculosis. Of the six in the incipient group one patient was in the pneumothorax class but was very irregular in attendance. The other five were in the observation group. Of the eight cases which had increased disease in the incipient group, all were in the observation class.

TABLE 1.—*Mortality*

	Number	Deaths	Increased Involvement
Incipient tuberculosis.....	45	6 (13.33%)	8 (17.77%)
Advanced tuberculosis.....	20	1 (5%)	0

It would seem then that the chief reasons for the discrepancy in our results was either lack of active treatment for the early cases, inadequate observation or both.

A review of the literature was disappointing. While there were many follow-ups on positive reactors which disclosed numerous cases of tuberculosis and numerous articles showing results of various types of treatment and occasional reports on rechecks of arrested cases, no reports such as ours could be found. For some time we have wondered whether these poor results are peculiar to this region. We feel that a thorough follow-up of tuberculosis observation cases in any group would disclose similar results. At the St. Louis meeting of the Mississippi Valley Conference in 1938 Dr. Chadwick in a striking paper showed that over a ten year period of follow-up in Massachusetts the death rate from these early cases in school children was up to 73 per cent. These figures demonstrate quite well the inadequacy of treatment and follow-up.

For all this we, the physicians, must accept the blame, for if the patient is negligent it is because we have failed to teach and impress him. What usually obtains

TABLE 2.—*Treatment*

		Observation 23		12

is as follows (table 2): In the twenty-two incipient cases actively treated the results are good, as in the advanced cases actively treated. Most of our grief comes from the observation group. It would seem then that the latter group should be abolished. This would no doubt solve our problem. This, however, is often impossible. The story of those in this observation class is usually as follows:

A patient outwardly in good health and ofttimes obese will be found to have a suggestive or minimal lesion. Attempts at confining such a person to bed or using pneumothorax are often rebelled against. His knowledge of tuberculosis is at best rudimentary. His appetite is good, he has lost no weight, he is not tired, he has no cough and no fever. Suddenly he is told by a physician that he has tuberculosis or a suspicious case of tuberculosis. He is advised bed rest but refuses to submit. In this he is often unwittingly aided by his physician. The doctor, well meaning but not versed in tuberculosis, failed to read a minimal lesion into the x-ray examination. So as a compromise the patient is advised to lead a normal life, avoid fatigue, take a high caloric, high vitamin diet, and avail himself of fresh air and sunshine and return for observation. Let us say he does this; he is seen every month or two by the tuberculosis clinic, where he is not given any additional treatment or advice but told to keep coming back. Soon he falls into disbelief and fails to return and resumes a strenuous life. The next time he is seen he may have an advanced case.

Also the tendency is to minimize the observations. This is done because we do not wish to frighten the patient and because often we, as physicians, cannot reconcile tuberculosis to a minimal, seeming harmless lesion on the roentgenogram in a robust physical specimen. Again, two seemingly identical patients may be treated alike, both put on observation and controlled work, and one will get along well while the other breaks down. There is no method of determining which of these lesions will progress to far advanced tuberculosis.

The answer lies probably in active treatment more frequently and in closer surveillance of the observa-

tion cases so any tendency to increased involvement may be noted and treated with active measures.

There is yet another group of patients who are being neglected. This group is made up of patients who have a positive tuberculin test with a negative chest roentgenogram. The tendency is to say that they are healthy and that no special care is needed.

In our work we have many such cases; just recently we have had two fatalities in this group. Both of these students had a positive tuberculin reaction and were diagnosed as having healthy chests. They were dead of tuberculosis within two and one-half years.

Not only must the medical profession continue its progress in this disease against known cases but must extend its efforts to include routine roentgenograms of all positive reactors and annual retesting for all negative reactors. Then and only then shall we be completely successful in our campaign against tuberculosis.

360 North Michigan Avenue

A CEREBELLAR SIGN

ROBERT WARTENBERG, M.D.
SAN FRANCISCO

The pendular movement of the arm in walking is frequently found to be reduced or absent in patients with pyramidal or extrapyramidal disease. My purpose in this article is to point out that unilateral decrease or cessation of the arm-swinging movement in walking may be due also to disease of the cerebellum. This finding may constitute a fine and early sign of the involvement of the homolateral cerebellar hemisphere. When in 1930 I reported this clinical observation to my former teacher, the late Dr. Kinnier Wilson, he said that he considered it of great interest and worthy of further study. In the same year I read a short paper [1] on this cerebellar sign at the Congress of the German Neurologists in Dresden. In an article in 1931 Mann [2] concluded from his own experience that this sign deserves "marked attention." Marburg [3] referred to my first observation as extremely interesting and as standing alone in the literature and stated in his monograph on the cerebellum [4] that these changes of the swinging movement of the arm in walking "appear to be an extraordinarily important sign of an affection of the lateral lobes of the cerebellum." Bing [5] gave the same opinion.

These comments, together with later confirmatory observations, warrant a short review of the subject.

My attention was drawn to this sign during observation, some years ago, of a girl aged 12 who complained of headache and vomiting of three months' duration. Examination showed the following signs: pressure pulse; choked disks; nystagmus, of larger amplitude to the right, a very slight adiadokokinesis of the right hand, a fine intention tremor of the right arm and a slight uncertainty in walking in the position of a rope dancer, with a tendency to deviate more to the right. However, the most striking sign the patient presented was a complete loss of the pendular movement of the right arm in walking. The arm, hanging down, was completely flaccid. This was still more conspicuous because this arm did not show any pyramidal or extrapyramidal sign and only slight cerebellar signs. It was remarkable that the patient was not particularly handicapped in the use of her right hand and arm. The clinical diagnosis was "tumor of the posterior fossa, in all probability within the right cerebellar hemisphere and more likely in the upper than in the lower part." At the operation performed by Dr. Sauerbruch in Berlin a sharply defined tumor (a fibrosarcoma the size of a hazelnut) was removed from the middle of the right cerebellar hemisphere.

Four months afterward the child had no complaints. The disks were not choked but there were slight nystagmus, questionable adiadokokinesis of the right hand and a trace of intention tremor of the right arm. The pendular movements of the right arm in walking had become normal.

The condition had progressed thus far at the time of my first communication in 1930. Annual examinations were made during the following three years and the results remained the same. In the fourth year the child complained of dizziness and double vision. Neurologic and ophthalmic examinations did not reveal any new sign except that the pendular movements of the right arm had again become distinctly diminished. A month later the patient was admitted to the surgical clinic of Dr. Sauerbruch in Berlin complaining of dizziness, double vision and strabismus. The clinic reported to me that the patient had palsy of the right rectus lateralis and rectus superior muscles and nystagmus to the right. A diagnosis was made of cyst or recurrence of tumor. Incision was made over the formerly treated area; a cyst in the right cerebellar hemisphere was punctured, and under this cyst a solid tumor the size of a hen's egg was found and extirpated. One branch of the tumor extended into the depths as far as the worm and projected into the fourth ventricle. When discharged from the clinic, the patient had fully recovered.

These operations had to some extent the value of a crucial experiment on the problem of the influence of the cerebellum on the swinging movement of the arm in walking. First, after removal of a tumor from the right cerebellar hemisphere the lost pendular movement of the right arm reappeared. Second, the renewed loss of the pendular movement of the homolateral arm was the first sign that indicated recurrence of the lesion.

Because of the observations made in this case, swinging of the arm in walking was studied in other cases of cerebellar disease. This movement was found to be definitely decreased or even lost in unilateral cerebellar diseases, such as tumor of the cerebellum or of the cerebellopontile angle, and in other conditions difficult to classify involving one cerebellar hemisphere. Particularly remarkable among the cases observed was one in which [6] the syndrome indicated the presence of a tumor on the lower surface of the right cerebellar hemisphere. In this instance the pendular movement in walking was markedly reduced on the right side. After large doses of iodine had been given and roentgen

treatment had been applied, all the signs of the tumor subsided markedly and the pendular movement of the right arm became nearly normal. The condition may have been arachnoiditis serosa cystica of the posterior fossa. In most cases of unilateral acoustic tumor with cerebellar involvement the loss of the arm-swinging movement on the homolateral side was found to be complete; this sign appeared early and constituted a conspicuous part of the clinical picture. At the beginning of involvement of the cerebellum during the development of a tumor at the cerebellopontile angle, sometimes only two signs of this involvement were detectable. These were a slight deviation to the affected side in walking and decrease of pendular movement of the arm on the same side.

In two cases of olivopontocerebellar atrophy a diminution of the arm-swinging movement was found, more pronounced on the predominantly affected side. In some neurologic cases difficult to diagnose, special attention to this sign was helpful and led finally to the correct diagnosis.

A remarkable syndrome was found in cases of injury to the brain that affected chiefly one side of the posterior fossa. This consisted of the following unilateral signs: (1) palsy or weakness of the conjugate movement of the eyes in one direction, (2) loss of the vestibular reactions on the side affected, and (3) loss or decrease of pendular movement of the arm on the same side. A similar syndrome has been described by Mann.[2] He found in cases of concussion and of contusion of the brain the following signs, all of which appeared unilaterally on the side affected: (1) impairment of movement of the eye to one side; (2) a positive Romberg sign; (3) past pointing in Bárány's test; (4) loss of the swinging movement of the arm in walking (called by Mann the "Wartenberg sign") and (5) diminution of the corneal reflex. The unilateral loss of the pendular movement of the arm was in these cases part of a syndrome which pointed definitely to a unilateral disease of the posterior fossa. Mann assumed that this syndrome indicated a unilateral traumatic involvement of the corpus restiforme or neighboring structures.

In cerebellar disease, chiefly disturbance of synergy in the legs is seen, because, generally speaking, in man the arms are subject in a lesser degree to the coordinating influence of the cerebellum than are the legs. In the cases just described a disturbance of synergy in an arm resulted in a loss or decrease of its pendular movement in walking, and in our cases this sign has been found in combination with other signs and symptoms that point definitely to disorders of the cerebellum or at least of the posterior fossa.

My justification for relating this disorder of the pendular movement of the arm to involvement of the cerebellum lies in the fact that this sign was found in strictly unilateral injuries of the cerebellum. In 1918 Thomas[7] described the gait of two of his patients (Ghi. and Hy) who had unilateral injuries of the cerebellum, stating that in the first week of their stay in the hospital the arm on the affected side swung in walking, but "later on the arm appeared to become immobilized intentionally and constantly in the same position, as if to avoid swinging." In another work[8] the same author, describing signs of impairment of function of the cerebellum, wrote "The upper extremity swings or else it is held motionless and no longer accompanies the movements of the lower extremity." In describing the clinical signs of unilateral cerebellar injury, Holmes[9] stated: "Another example of asynergia is furnished by the fact as the patient walks the affected arm hangs inertly by his side and does not swing synchronously with the movements of the opposite leg." In his Croonian lectures on the clinical symptoms of cerebellar disease,[10] the same author described the gait of a patient with a unilateral cerebellar lesion as follows: "In walking, the homolateral arm usually hangs inertly by his side and is not swung actively forward as he advances the opposite foot; sometimes, however, it is held against the thorax or abducted from it with the elbow partially flexed." Babonneix and Sigwald[11] noted the loss of pendular movement of one arm in a case of cerebellar tumor, and Folly[12] reported the same finding in a case of meningeal hemorrhage over one cerebellar hemisphere. Dusser de Barenne[13] mentioned that in cerebellar lesions "the normal pendular movement of the arm as a movement coordinated with the heterolateral leg is disturbed." Henner[14] said the same thing. Marburg,[4] who observed this phenomenon years ago, mentioned in his monograph on the cerebellum a case of strictly unilateral involvement of the cerebellum in which the pendular movements of the arm were absent on the affected side.

In the light of my own experience and from data gathered from the literature, there is little doubt that the unilateral decrease or loss of the pendular movement of the arm constitutes a sign which can be produced by a lesion of the cerebellar hemisphere. However, it should be pointed out that, aside from the references I have cited, there is little mention of this subject in the literature. Alteration of the pendular movement of the arm in unilateral cerebellar disease is mentioned in hardly any textbook of neurology in English, German or French. Numerous personal communications indicate that this sign is but little known. It is not, for example, even referred to in the Proceedings of the Association for Research in Nervous and Mental Diseases of 1926 devoted to discussion of the cerebellum, in the report of the Symposium on the Cerebellum held at the combined meeting of the Section of Neurology of the Royal Society of Medicine and the American Neurological Association in London in 1927 or in the review of cerebellar symptoms and signs by Mills and Weisenburg.[15] It is not mentioned in Cushing's monograph on "Tumors of the Nervus Acusticus,"[16] a disease in which I have found this sign pronounced and of diagnostic importance.

From the physiologic standpoint this disturbance of the normal swinging movement of the arm in walking in a disease of the cerebellar hemisphere is easily understandable. The fundamental sign of a cerebellar lesion is asynergia, which has been defined by Babinski as "the inability to accomplish simultaneously the various

movements that constitute an act." The normal coordination of the various contracting muscles is disturbed. This may be noted, for instance, in the dissociation of the ordinarily synergic movements of finger and wrist and in the failure of synchronism in the movements of the head and eyes in looking toward one side. The loss of synergic movement in walking—i. e. the simultaneous bringing forward of one arm and the contralateral leg—belongs in the same group of disturbances. Here the synergic movement of the trunk with that of the muscles of the extremity is disturbed.

Thus it is certainly justifiable from both a clinical and a physiologic standpoint to attribute the unilateral reduction or cessation of pendular movement of the arm in walking to an involvement of the homolateral cerebellar hemisphere.

This sign may be produced by extrapyramidal and pyramidal disease, but it is my object in this article simply to point out that it may also be a sign of exclusively cerebellar disease. It is my definite impression that a cerebellar disease influences the pendular movement earlier and more pronouncedly than does a cerebral disorder.

The clinical importance of this sign lies in the fact that it is easily detectable, can hardly be simulated and constitutes an early sign of cerebellar involvement, as is shown especially in the first case described in this paper. In 1930 Holmes [17] stated "Only today I saw what I believe is an early tumour of the right side of the cerebellum, and in this case the only signs were a little nystagmus to the right and absence of the normal swinging movements in the right arm."

The whole problem of the clinical significance of the pendular movement of the arm deserves more attention and study. It raises intricate problems which still await solution. I have observed a few cases with signs of increased intracranial pressure, in which no explanation could be found for the unilateral loss of swinging movement of the arm in walking. Also puzzling was a case reported by Fischer and Pötzl [18] in which resection of one cerebellar hemisphere had been followed by return of the pendular movements to normal. Concerning the question of exact localization of this sign, it may be of interest that in a case of tumor of the cerebellar worm, verified post mortem, the swinging movement of both arms had been normal. This has also been true in cases of multiple sclerosis with marked cerebellar gait.

In the light of knowledge of the relation of the cerebrum to the cerebellum, and especially in view of recent experiments by Aring and Fulton,[19] it would be of interest to study the swinging movement of the arm in unilateral frontal disease.

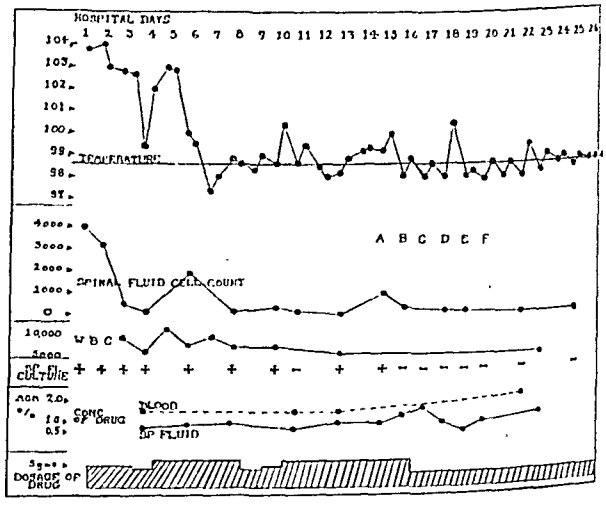
Fertility.—Among all those producing children in the United States in 1934 there were forty-four women past their forty-seventh birthday, and therefore practically at the end of their fecund life, who brought forth in that year their first and only live births. In the same year there were two women of an extremely different order of proven breeding capacity. Each one of them, apparently quite in her stride, produced her twenty-seventh child.—Pearl, Raymond: The Natural History of Population, New York, Oxford University Press, 1939.



Clinical Notes, Suggestions and New Instruments

PNEUMOCOCCIC MENINGITIS SUCCESSFULLY TREATED WITH SULFAPYRIDINE

MORGAN CUTTS, M.D.; K. K. GREGORY, M.D., AND EDWARD J. WEST, M.D., PROVIDENCE, R. I.

Two reports [1] of the successful treatment of pneumococcic meningitis with 2-(*p*-aminobenzenesulfonamido) pyridine (sulfapyridine) have recently appeared from England. In view of the rarity of recovery from this disease and the apparent effectiveness of this new drug [2] in the condition, the following case is presented:

B. A., a white girl aged 14 years, admitted to the Charles V. Chapin Hospital Nov. 16, 1938, had had a nonproductive cough for two weeks but did not feel sick until three days before admission. At this time headache, projectile vomiting, increasing restlessness and a rise in temperature suddenly developed. She was delirious on admission. The temperature was 103.6 F., the pulse 104, the respiratory rate 26. The blood pressure was 98 systolic, 62 diastolic. Her neck was stiff and the Kernig sign

Course of treatment in the case of pneumococcic meningitis here presented. *A* indicates the intraspinal injection of 10 cc. of complement; *B*, 6 cc. of complement and 6 cc. of type XX rabbit serum; *C*, 5 cc. of type XX rabbit serum; *D*, 10 cc. of complement and 10 cc. of type XX rabbit serum; *E*, 9 cc. of complement and 9 cc. of type XX rabbit serum; *F*, 6 cc. of complement and 6 cc. of type XX rabbit serum.

was present. Physical examination showed no other abnormalities. In particular the lungs were clear, and no origin of the infection was found in the ears, nose or throat. A lumbar puncture revealed cloudy fluid, under increased pressure, which on culture yielded pneumococcus type XX. Two blood cultures yielded negative results.

The day after admission the oral administration of the drug was begun. The daily dose was approximately that recommended by Evans and Gaisford.[3] The clinical improvement, as shown in the accompanying chart, was prompt and striking. One week after admission her temperature had returned to normal, the spinal fluid had cleared markedly and she was alert and asymptomatic. Cultures of the spinal fluid, however, continued to yield positive results, so intraspinal treatment with complement (from the patient's own serum) and specific anti-pneumococcus rabbit serum was begun on the fifteenth hospital day. Following this the cultures became negative and remained

From the Charles V. Chapin Hospital.
The drug used in this case was supplied by Merck & Co., Rahway, N. J., under the trade name of "Dagenan." The type XX antipneumococcus rabbit serum was supplied by Lederle, New York.

so. The patient was discharged well six weeks after admission and ten days after all treatment was discontinued.

No toxic symptoms of any importance were noted that could be ascribed to the drug. There was some headache and nausea early in the treatment, but these may well have been due to the infection. The carbon dioxide combining power of the blood remained normal and there was only a slight drop in the hemoglobin content to 79 per cent. Sugar determinations of the spinal fluid showed a lowering to 28 mg. per hundred cubic centimeters and a return toward normal that lagged somewhat behind the other laboratory observations.

The concentrations of the drug as shown on the chart seem remarkably low, never exceeding 2.2 mg. per hundred cubic centimeters in the blood and 1.7 mg. in the spinal fluid. This can be only partly explained by the method used, that of Schmidt,[4] which, as shown by parallel determinations by us, gives results for this drug about 25 per cent lower than that of Marshall.[5]

Capsular degeneration of pneumococci and their failure to type after exposure to this drug was first mentioned by Whitby.[6] In this case capsule stains were inconclusive, but the organisms showed capsular swelling in specific typing serums as long as they were obtained from the spinal fluid. No significant change in their high virulence for mice was noted during the course of treatment. At no time were agglutinins for this organism present in the patient's serum.

Apparently in this case drug therapy, while producing marked clinical improvement, was not alone effective in eradicating the meningeal infection. The final cure was brought about by a combination of drug and serum therapy.

203 Thayer Street.

DERMATITIS FROM ORTHODICHLOROBENZENE

JOHN G. DOWNING, M.D., BOSTON

Orthodichlorobenzene has become industrially important in the past few years. In addition to its other uses it serves as an effective solvent in lacquers, varnishes and waxes. It is used extensively for the preservation of wood because of its destructive effect on termites. Orthochlorophenol is also used as a wood preserver.

Orthodichlorobenzene consists of benzene with two of its hydrogen atoms replaced by chlorine; the prefix "ortho" means that the two chlorine atoms are on adjacent carbon atoms. Orthochlorophenol consists of phenol in which the hydrogen atom on one of the carbon atoms has been replaced by chlorine.

The toxicity of these materials will bear observation. Little is known of the chlorobenzenes or chlorophenols, but of the chloronaphthalenes, which are related products, some are apparently nontoxic to the liver when inhaled while those that are toxic when inhaled are severe irritants of the skin. It is therefore considered of value to report the following case:

S. B., a glazier aged 47, examined Oct. 5, 1937, had been handling window sashes which had been dipped in a mixture containing various chemicals. He inserted window glass in the sash with a putty which he himself had prepared with linseed oil. Near the end of July he noticed an itchy eruption, consisting of water blisters, on his face, hands and arms. He was treated at three local hospitals without relief; he used various local applications which enabled him to continue work, although on three occasions he had to stop for several days. While he was away from work his eruption was relieved, only to break out again when he returned.

Physical examination October 5 showed an eczematoid dermatitis of the hands, arms and face. The patient was to be tested with the various substances with which he came in contact at his work, but while preparing them I applied a small amount of the window sash solution to the skin and within a few minutes there was a marked positive reaction. Later I tested the patient by dropping on the skin the various ingredients contained in the dipping solution, namely mineral spirits, chlorortho phenylphenol and orthodichlorobenzene. The tests were negative except for that with orthodichlorobenzene. Two minutes after this was dropped on one arm intense erythema and edema developed at the site of the application and for one-half inch surrounding it. Later a large bullous lesion formed in the center of this area.

This case demonstrates the irritative properties of orthodichlorobenzene and shows that chemicals of unknown property should not be applied to the skin in the usual patch test manner, namely in an occlusive dressing, but should be dropped or painted on the skin and observed carefully for at least an hour.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

"VITAMIN K," A PRINCIPLE USEFUL IN CERTAIN HEMORRHAGIC CONDITIONS

THE COOPERATIVE COMMITTEE ON VITAMINS, REPRESENTING A COMBINED COMMITTEE OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND THE COUNCIL ON FOODS, CONSIDERED THE EVIDENCE FOR A PRINCIPLE CALLED "VITAMIN K," REPORTED TO BE USEFUL IN THE TREATMENT OF CERTAIN HEMORRHAGIC CONDITIONS. THE COMMITTEE RECOMMENDED THAT A PRELIMINARY REPORT BE ISSUED ON THIS PRINCIPLE AND THE RECOMMENDATION WAS ADOPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY. DR. SNELL OF THE MAYO FOUNDATION, WHO HAS BEEN WORKING WITH THIS PRINCIPLE, PREPARED THE APPENDED REPORT WHICH HAS BEEN ADOPTED BY THE COUNCIL FOR PUBLICATION AS A PRELIMINARY REPORT. THE COUNCIL AGREES WITH THE AUTHOR THAT THE PRINCIPLE KNOWN AS VITAMIN K APPEARS TO HAVE THERAPEUTIC USEFULNESS IN THE HEMORRHAGIC MANIFESTATIONS OF HEPATIC AND BILIARY DISEASE. THE COUNCIL HAS AUTHORIZED ITS COMMITTEE ON NOMENCLATURE TO STUDY THE QUESTION OF A SUITABLE NONPROPRIETARY NAME WHICH SHALL NOT BE THERAPEUTICALLY SUGGESTIVE. THE COUNCIL VOTED ALSO TO CONSIDER WITH VIEW OF ACCEPTANCE BRANDS OF "VITAMIN K" UNDER STRICTLY LIMITED CLAIMS FOR USEFULNESS IN THE HEMORRHAGIC DIATHESIS OF HEPATIC AND BILIARY DISEASE; THE COUNCIL AUTHORIZED PUBLICATION OF THE APPENDED REPORT.

PAUL NICHOLAS LEECH, Secretary.

VITAMIN K: ITS PROPERTIES, DISTRIBUTION AND CLINICAL IMPORTANCE

A PRELIMINARY REPORT

ALBERT M. SNELL, M.D.
ROCHESTER, MINN.

In 1935 Dam [1] of Copenhagen observed that newly hatched chicks maintained on a diet which was deficient in certain fat-soluble materials, but otherwise adequate in respect to protein, minerals and all known vitamins, suffered from a fatal hemorrhagic diathesis characterized by bleeding from the pinfeathers, hemorrhages into the subcutaneous tissues and muscles and gizzard erosions. The hemorrhagic tendency in these chicks was associated with, and apparently due to, a fall in the concentration of prothrombin in the blood. The condition could be controlled or prevented by administration of the nonsaponifiable, nonsterol fraction of hog liver fat or by feeding alfalfa.[2] The protective, antihemorrhagic factor present in these last mentioned materials was tentatively named by Dam the "koagulations vitamin," or vitamin K.

DISTRIBUTION, PHYSICAL AND CHEMICAL PROPERTIES

Vitamin K, or at least substances possessing similar biologic properties, are widely distributed in nature. In the plant kingdom the distribution appears to be con-

1. Dam, Henrik: The Antihaemorrhagic Vitamin of the Chick, Biochem. J. **29**: 1273-1285 (June) 1935.
2. Almquist, H. J., and Stokstad, E. L. R.: Dietary Hemorrhagic Disease in Chicks, Nature **136**: 31 (July 6) 1935.

fined almost entirely to the photosynthetic portion of the plant, considerable amounts having been found in alfalfa, kale, spinach, dried carrot tops, chestnut leaves, tomatoes and oat sprouts. In addition, vitamin K is found in soy bean oil and some other vegetable oils but is not present in significant amounts in fish liver oils.

The vitamin can also be prepared from fish meal, rice bran or casein after the extracted material has been allowed to putrefy, bacteria apparently effecting the synthesis of the vitamin under such conditions. Almquist and his associates [3] have isolated a "fish meal organism" which closely resembles Bacillus cereus and which contains, and is capable of producing in fish meal, considerable amounts of vitamin K. The vitamin is also present in dried Escherichia coli, Bacillus subtilis, Staphylococcus aureus and many other micro-organisms, presumably being contained in the lipoid fraction of these bacteria. Vitamin K may also be produced by bacterial activity in the intestinal tract and is present in the droppings of chicks and in both normal and acholic feces of man.

The physical and chemical properties of the vitamin are now being investigated, but little exact information is available at present. Almquist [4] has prepared a colorless, crystalline, fat-soluble material which is heat stable but which is rapidly destroyed by alkalis or sunlight. This substance is probably a complex, unsaturated hydrocarbon of high molecular weight; [5] it contains a small amount of nitrogen but no sulfur or phosphorus. Thayer, Doisy and their collaborators [6] also have isolated a crystalline compound of high potency from alfalfa leaves. The crystals have a melting point of 69 C. and appear as small, transparent plates. These investigators pointed out that the vitamin may be adsorbed on these crystals and that there is evidence of more than one substance with antihemorrhagic activity in their extracts. Almquist [7] has shown that the factor preventing gizzard erosions in chicks is not identical with vitamin K, and Lichtman and Chambers [8] have recently prepared a sterol, an alkali stable material with vitamin K activity, from liver fat. Possibly several closely related substances having some antihemorrhagic properties are present in crude extracts of alfalfa or putrefied fish meal. Present methods of assay are hardly sufficiently specific to identify such compounds, depending as they do on biologic methods alone. The antihemorrhagic properties of any given material can be determined only by its activity on K-avitaminous chicks. Some attempts have been made to establish a unit of measurement for the vitamin on this basis. Dann [9] has defined a unit as the least amount per gram of a chick's body weight daily which is necessary to prevent prolongation of clotting time beyond normal limits. Dam's unit is defined as the amount of antihemorrhagic material contained in 1 Gm. of dried spinach. Until more information is available with regard to the chemical and biologic properties of the vitamin, any attempts to establish a "unit" are necessarily somewhat arbitrary and of limited value.

CLINICAL USE OF VITAMIN K

The use of the antihemorrhagic vitamin in clinical medicine depends on the following facts: (1) that in obstructive jaundice and in disease of the parenchyma of the liver there is a deficiency of prothrombin in the plasma, and (2) that this deficiency represents one manifestation of K-avitaminosis, although the stools of such patients can be shown to contain the vitamin. The deficient formation of prothrombin in such patients depends in part on a failure of absorption of fat soluble substances when bile is excluded from the intestinal tract, or when the secretion of bile salts by the liver is reduced. There is also another and perhaps a more important factor, namely the ability of the liver to utilize vitamin K in the formation of prothrombin. To discuss all the clinical and experimental data bearing on this subject is beyond the scope of this report, but certain studies may be cited.

Quick [10] was apparently the first to call attention to a deficiency of prothrombin in the blood of jaundiced patients; he established this point by the method of adding optimal amounts of thromboplastin to recalcified plasma, leaving prothrombin as the only variable and then recording the coagulation time of this mixture. Smith and his associates [11] have amply confirmed this observation by a quantitative study of prothrombin in cases of jaundice. Hawkins and Brinkhous [12] have demonstrated by the last-mentioned method a similar deficiency of prothrombin in dogs with complete biliary fistula and have shown that the feeding of bile to these animals will produce a rise in the concentration of prothrombin and cessation of bleeding, if present. Bile feeding has been shown to produce a comparable effect in cases of obstructive jaundice. The role of hepatic injury in the synthesis of prothrombin has been studied by Smith, Warner and Brinkhous,[13] who found that in experimental chloroform intoxication a marked deficiency in prothrombin could be produced. An earlier observation bearing on this point was made by Roderick,[14] who noted a deficiency of prothrombin in cattle with toxic sweet clover disease, a condition which is associated with necrosis of the liver.

Reports on the treatment of the hemorrhagic diathesis in obstructive jaundice have recently appeared from the University of Iowa [15] and from the Mayo Clinic.[16]

Butt, Snell and Osterberg.[19]

These studies, which were made independently, show that a definite reduction in the prothrombin clotting time (Quick), an increase in the quantitative level of prothrombin in the blood, and even control of actual hemorrhagic states can be accomplished by the oral administration of extracts of alfalfa or of putrefied fish meal, together with bile or bile salts. It has been emphasized that adequate preoperative treatment with these materials will greatly reduce the hemorrhagic tendency commonly observed in cases of jaundice. However, such treatment may not ensure normal blood coagulation in the postoperative state, since a marked fall in the concentration of prothrombin may occur in many cases following operation. The large excess of prothrombin in mammalian blood may be sufficient to protect such patients, but in others serious bleeding may take place. Even in patients presenting marked depletion of prothrombin the control of the hemorrhagic state is possible by the use of large doses of vitamin K concentrates and bile salts. Rapid correction of the coagulation defect has been observed even in the presence of complete biliary obstruction and hepatic injury; the rate of prothrombin formation seems to follow the chemical laws of mass action.

In view of the fact that standard methods of determining the coagulation time of blood give little warning of the possibilities of hemorrhage in cases of jaundice, it is advisable either to use vitamin K concentrates and bile salts as a routine part of preoperative and postoperative treatment or to be guided by some of the various indirect methods now in use for the detection of a deficiency in prothrombin. Of these the Quick prothrombin time is perhaps the most satisfactory for general use; the quantitative determination of prothrombin by the method of Smith and his collaborators [11] is technically difficult but very reliable. Dam and his associates [17] in their investigations have used a modification of the Fisher method for determining the clotting time of avian blood. The earlier one is able to detect by laboratory means the first signs of impending prothrombin deficiency, the less vitamin concentrate is required for its control and the less the danger of serious loss of blood.

The amounts of material required for prophylactic or curative treatment are still under investigation. For the former, the daily use of from 400 to 800 mg. of an alfalfa concentrate (2,000 to 4,000 Dann units) with 1 to 2 Gm. of bile salts has been advised; for the latter from 1 to 3 Gm. (5,000 to 15,000 Dann units) plus fistula bile, lyophilized bile or from 2 to 4 Gm. of animal bile salts may be administered by duodenal tube at appropriate intervals. One or two such doses are usually sufficient to raise the concentration of prothrombin to a safe level. Dam and Glavind [18] have advocated the parenteral use of vitamin K concentrate in oil and have shown a gradual reduction in clotting time following such treatment. The Mayo Clinic investigators,[19] however, have found that doses of 1 Gm. or more of the material, administered parenterally, are decidedly less effective and much more slowly utilized by the body than are similar amounts given directly into the intestinal tract.

Up to the present, little is known of the effect of vitamin K in other hemorrhagic diseases. In the light of present knowledge there is no reason to expect a favorable effect if the prothrombin content of blood is normal. In cases of sprue and in cases of extensive regional ileitis, deficiency in prothrombin because of an insufficient intestinal absorption of vitamin K has been noted, and in such circumstances there are theoretical reasons for administration of the vitamin. Purpuric states, hemophilia and essential hematuria are not affected by vitamin K therapy; on the other hand, recurrent hemorrhagic retinitis and certain forms of functional menorrhagia are said to have shown some response.

Indiscriminate use of vitamin K in hemorrhagic diseases of all types should be discouraged, although to date there has been no evidence of any toxic effects even with very large doses. Work is in progress at present on the chemical structure of the vitamin and related compounds, on the relation of the vitamin to prothrombin and on the metabolism of the latter substance in other diseases. Until these studies are completed, therapeutic efforts with vitamin K are best confined to the hemorrhagic diathesis of hepatic and biliary disease, in which the results appear to be almost specific.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

CINCHOPHEN (See New and Nonofficial Remedies, 1938, p. 177).

CINCHOPHEN-THE UPJOHN COMPANY.—A brand of cinchophen-N. F.

Manufactured by The Upjohn Company, Kalamazoo, Mich.
Tablets Cinchophen-The Upjohn Co., 5 grains.
Tablets Cinchophen-The Upjohn Co., 7½ grains.

EPHEDRINE SULFATE (See New and Nonofficial Remedies, 1939, p. 228).

EPHEDRINE SULFATE-MERRELL.—A brand of ephedrine sulfate-U. S. P.

Manufactured by Wm. S. Merrell Co., Cincinnati, Ohio. No U. S. patent or trademark.
Ampule Solution Ephedrine Sulfate-Merrell, 0.05 Gm. (¾ grain), 1 cc.

MERCURIC SUCCINIMIDE (See New and Nonofficial Remedies, 1938, p. 299).

Ampule Solution Mercury Succinimide-Merrell, 0.01 Gm. (⅙ grain), 1 cc.
Prepared by the Wm. S. Merrell Co., Cincinnati, Ohio. No U. S. patent or trademark.

NICOTINIC ACID (See THE JOURNAL, July 2, 1938, p. 27, and the Revised Supplement to N. N. R., 1938, p. 22).

Nicotinic Acid-Merck.—A brand of nicotinic acid-N. N. R.

Manufactured by Merck & Co., Rahway, New Jersey. No U. S. patent or trademark.

SODIUM THIOSULFATE (See New and Nonofficial Remedies, 1938, p. 450).

Ampuls Solution Sodium Thiosulfate-Maltbie, 1 Gm. (15½ grains), 10 cc.
Prepared by The Maltbie Chemical Company, Newark, N. J.

CANINE ABORTION AND HUMAN PARATYPHOID

Veterinarians have long suggested that dogs are susceptible to human paratyphoid B infections and that under certain conditions they may be the sole source of transmission of this disease to man. Two years ago a local epidemic of paratyphoid was noted in an isolated Swedish village. Two weeks before the beginning of the epidemic a pregnant setter of the village had suffered a severe gastro-enteritis and had aborted. After the development of the epidemic the local physician [1] took samples of stools, urine and blood from the convalescent dog. The blood sample gave a positive Widal reaction with a standard laboratory strain of Salmonella paratyphi B (schottmülleri). Both convalescent urine and stools, however, were negative at the time of the examination.

A year later a second local paratyphoid epidemic was noted in another isolated Swedish village. This epidemic also was accompanied with one or more cases of canine abortion. An atypical paratyphoid bacillus was isolated in the human cases. The dogs were not examined. As a precautionary measure, however, a valuable pregnant dog was sent from this village to an isolated farm about 4 kilometers distant. Two days after arrival the dog became desperately ill with enteritis and aborted. Following this abortion, four members of the rural family caring for the dog became ill with typical paratyphoid infection. Blood and stools were collected by the attending physician [2] from the four patients and from the dog and sent to the National Laboratory at Stockholm for bacteriologic examination. An atypical paratyphoid strain was isolated from each of the five stools. All five blood samples gave positive agglutinin reactions with this strain, the canine serum agglutinating it in a dilution of 1:250.

Fractional antigens were isolated from this bacillus and compared with similar fractions from standard laboratory strains. At least four heterophile antigenic factors were demonstrated or deduced from cross agglutination tests, together with one fairly specific factor, which was tentatively assumed to be diagnostic of the canine bacillus. The name Salmonella abortus canis was suggested for this canine paratyphoid B bacillus.

Theoretically the new micro-organism may be pictured as a relatively primitive, less highly specialized type of the paratyphoid bacillus, a possible ancestor of more highly specialized strains isolated in strictly human cases. The cultural stability of this canine variant has not yet been tested.

BAKER AND KOCH "CANCER CURES" TRY NEW ZEALAND

According to a report in the *British Medical Journal* the American "cancer cures" promoted by William F. Koch and Norman Baker have been investigated by a committee of qualified medical experts in New Zealand.[1] On Aug. 31, 1938, fifteen patients who had been treated by the Koch and Baker fluids were carefully examined by members of the committee. It was decided that six of the patients had cancer and six were probably cancerous, while three definitely did not have cancer. The examiners were especially interested in four cases of cancer of the breast which had been treated with local injections of the Baker [2] fluid around the periphery of the breast ten days prior to examination and also with intravenous injection of Koch's [3] fluid the day before. In each case the whole of the breast and a varying but extensive surrounding area were completely gangrenous, black and malodorous.

Dr. Williams, who administered the treatments, gave the committee the impression that Baker's fluid destroyed all cancerous tissue exclusively and selectively and that the Koch fluid searched out all cancerous cells throughout the body, wherever they might be, and destroyed them.

The patients were seen again on September 14, and two of them were decidedly worse. In all cases the cancerous breast had sloughed away, together with surrounding tissue extending in one instance from the center of the breast bone to the posterior margin of the armpit. With one exception there had been no signs of healing, and it was noted that it would require a long time for healing of such large areas to occur. There was a great amount of mutilation.

1. The committee which investigated these remedies consisted of Sir James Elliott, M.D., chairman, Mr. H. Hardwick-Smith, F.R.C.S., Dr. J. O. Mercer and Dr. T. R. Ritchie. Sir James Elliott is president of the New Zealand Branch of the British Empire Cancer Campaign, Dr. Mercer is a recognized pathologist (M.R.C.P.), and Dr. Ritchie is director of the Division of Public Hygiene of the Department of Health. This committee was acceptable to a Dr. Williams, who apparently is the one who requested the test.

2. Previous references to Norman Baker and his treatment of cancer appeared in THE JOURNAL **94**: 1146, 1241, 1340 (April 12, 19 and 26) 1930; **95**: 285 (July 26) 1930; **96**: 43, 1167, 2042 (Jan. 3, April 4 and June 13) 1931; **98**: 890, 1012 (March 12 and 19) 1932; **99**: 1355 (Oct. 15) 1932; **104**: 929 (March 16) 1935; **105**: 375 (Aug. 3) 1935; **109**: 375, 616, 798 (July 31, Aug. 21 and Sept. 4) 1937; **110**: 749 (March 5) 1938; **111**: 566 (Aug. 6) 1938; **112**: 435 (Feb. 4) 1939.

3. Previous references to William F. Koch and his treatment of cancer appeared in THE JOURNAL **76**: 466 and 537 (Feb. 12 and 19) 1921; **82**: 2054 (June 21) 1924; **86**: 1469 (May 8) 1926; **88**: 928 (March 19) 1927; **103**: 116 (July 14) 1934; **106**: 929 and 2189 (March 14 and June 20) 1936; **107**: 519 (Aug. 15) 1936.

About this time the investigations were ordered ceased by Dr. Williams, apparently for the reason outlined in a letter in which he said:

"Since both Baker and Koch have written to me in the strongest terms, declining to submit their products to test in their absence, I have no alternative to breaking up negotiations with your committee."

The committee, although thwarted in carrying its investigations to their indicated conclusion, stated:

"We have no doubt that Baker's fluid is a powerful sclerotic agent and can cause great local destruction. Compared with surgical treatment, destruction by a sclerosing or caustic fluid seems like a reversal to the treatment of the Middle Ages, causing unnecessary mental distress, delayed healing, and increased risk of septic infection. We have had no evidence whatever to show that Baker's fluid has any selective powers in the destruction of cancer cells. There is no real difficulty in removing the breast surgically or by crude destruction, but this is very far from a cure of the breast cancer and may delude the public mind. . . . From our general knowledge [4] and from the observations we were permitted to make in investigating the cases at Wanganui, we have no reason whatever to suppose that Koch's fluid has any effect in curing a generalized cancer. . . . This claim that a cure has been found for cancer should never be made and promulgated until prolonged tests have shown that the claim is a reasonable one. . . .

"Your committee considers that it is in the public interest that a statement should be made that our hope of finding anything useful in the treatment recommended by Dr. Williams and his colleagues has proved illusory."

The story speaks for itself. Nevertheless, it should be emphasized that the use of these treatments was permitted without any evidence in the scientific literature to support the use of either fluid. The committee's reference to the dark ages is particularly apt. In a day when medical science progresses on the basis of established fact, as determined by careful experimentation and even more careful clinical trial, with frequent reports in the literature covering the various steps, there is absolutely no excuse for the employment of methods of treatment completely devoid of scientific support.

4. The committee stated that it was influenced by investigations made of both the Baker and the Koch treatment in the United States of America under more favorable conditions, which had been uniformly condemnatory.

THE NUTRITIVE VALUE OF WHEAT FLOUR AND BREAD

Bread, throughout the ages, has been the symbol for food. The annual per capita consumption of wheat bread alone in the United States is over 80 pounds, and the yearly consumption of all types of bread is almost 90 pounds. Bread is a concentrated food and is one of the cheapest sources of energy. During the past three decades a large number of investigations have thrown light on the nutritive quality of bread. A recent report of Copping [1] reviews the present status of our knowledge of the problem.

Although bread is an important food, it is by no means a complete foodstuff. It consists essentially of flour and water, charged with carbon dioxide as a result of action of leavening agents, and baked. Its nutritive value depends principally on the flour used in its preparation. There is considerable variation in the nutritive value of flour. The process of milling wheat does not seriously affect the protein or the carbohydrate content of the flour, but it does appreciably reduce the amount of fat and ash present. Only about 70 per cent of the screened wheat is recovered in the preparation of standard grade white flour. By further milling finer flours are obtained and in these cases the extraction is even less.

The question of the extent to which various degrees of milling affect the nutritive value of the flour obtained from wheat is of particular importance. Although the preparation of flour from wheat by milling does not greatly alter the proportion of protein, experience indicates that the nutritive value of the protein of whole wheat is superior to that of the protein of various flours milled from it. In other words, in the modern process of milling the biologic value of wheat protein is lowered for nitrogen repair as well as for growth of the animal organism. The process of milling seriously affects the ash content of flour. The removal of wheat bran and wheat germ in the preparation of white flour effects a reduction in mineral content to about one half for calcium, one fourth for potassium, one fifth for phosphorus and one fifth for iron. The loss of calcium and phosphorus is probably not of great importance, as wheat, like most other cereals, shows an ill proportioned ratio of calcium to phosphorus. In this connection it has long been suspected that in the absence of vitamin D many cereals exert an anticalcifying effect and, as a consequence, an anticalcifying factor was alleged to be present in cereals. Recently, however, Mottram and Palmer [2] have shown that the rachitogenic effect of a pure cereal diet can be counteracted by merely adding sufficient calcium to produce a favorable calcium: phosphorus ratio. The loss of iron in the process of milling wheat is, however, of importance, since Rose and her co-workers [3] have shown that iron present in whole wheat meal is well absorbed and is efficiently used in the regeneration of hemoglobin.

Although wheat flour is practically devoid of vitamin D and vitamin C and ordinarily possesses but an insignificant amount of provitamin A, its content of the B group of water-soluble vitamins is not inconsiderable. An examination of white wheat bread, however, reveals that it contains only about one fourth to one sixth as much thiamin (vitamin B_1) as whole wheat bread. Investigation has also shown that bread prepared from whole wheat flour contains a larger percentage of the vitamin B complex than that prepared from white flour. Whole wheat grain contains an appreciable amount of provitamin A, carotene, but since this constituent imparts to the flour a yellow color which is considered undesirable, bleaching agents are often

3. Rose, Mary S.; Vahlteich, Ella M., and Bloomfield, Emily L.: Proc. Soc. Exper. Biol. & Med. **26**: 322 (Jan.) 1929.

used which destroy the color as well as a large percentage of the carotene. The germ of wheat has important nutritive properties. Rejection of wheat germ in the process of milling involves loss of an important source of these factors. Although little is known of the human requirement for these accessory food factors found in wheat germ, it seems probable, in the light of animal experimentation, that they are important for the nutrition of man.

Although it seems unfortunate that so much of the nutritive value of wheat grain is sacrificed by the modern process of milling, the predominant position of the cereals in the dietary justifies the position occupied by bread. By suitable supplementation with other foods, the essential economy of bread can be enjoyed without sacrificing the nutritional excellence of the dietary as a whole.

Current Comment

AMERICAN OPHTHALMOLOGICAL SOCIETY

In June of this year the American Ophthalmological Society will celebrate its seventy-fifth anniversary. On June 7, 1864, this society, the first in the United States devoted exclusively to ophthalmology, was formed. That first meeting was held at the New York Eye Infirmary with eighteen in attendance from New York, Boston, Philadelphia and Poughkeepsie. The society has always stood for the highest ideals in practice of medicine. Its imminent anniversary celebration serves to emphasize the increasing maturity of American scientific medicine.

EFFECTS OF VITAMIN B COMPLEX ON EXPERIMENTAL HYPERTHYROIDISM

The effect of crystalline thiamin chloride (vitamin B_1 hydrochloride) and the vitamin B complex (yeast) on experimental hyperthyroidism was studied by Drill and Sherwood [1] on rats fed various diets. The study was designed (1) to feed rats a synthetic diet containing sufficient amounts of yeast for growth, (2) to feed thyroid gland to rats receiving the same diet and produce a loss of weight, and (3) to administer crystalline thiamin chloride and additional yeast to the hyperthyroid rats while they were still receiving thyroid gland, in an effort to enable them to regain their lost weight. As a result of their carefully balanced and controlled experiments on rats, these investigators found that thiamin chloride and yeast will enable hyperthyroid rats which have lost weight to regain their lost weight while still receiving thyroid gland. One important factor in this result is the fact that thiamin chloride and yeast concentrate greatly stimulated the food intake of hyperthyroid rats. It is not, however, the only factor; although thiamin chloride will stimulate the food intake, the rats will not gain weight under the conditions employed until a rich source of the vitamin B complex is added to the diet. Furthermore, hyperthyroid rats limited to 13 Gm. of food will not stop losing weight even when thiamin chloride and yeast are administered, nor will thiamin chloride and yeast enable hyperthyroid rats that are entering into the diestrum to maintain a normal estrous cycle. In fact, the estrual cycle of normal rats is not influenced by the daily injection of 500 micrograms of thiamin chloride for as long as forty-four days. These interesting experiments shed additional light on the function of these vitamin complexes in relation to the action of the thyroid gland, at least in the experimental animal used.

SYNERGIC ALLERGY IN TUBERCULOSIS

The demonstration by Sabin and Joyner [1] of the Rockefeller Institute that a mixture of tuberculoproteins and phosphatides causes a degree of sensitivity in laboratory animals comparable to that occurring in natural infections is important as a contribution to the newer theories of synergic immunity. The result renews hope of the ultimate development of a nonviable tuberculosis vaccine. Earlier work with antigenic fraction from the tubercle bacillus has been uniformly disappointing. Forty years of intensive research with these antigens led to the generally accepted conclusion that a nonviable tuberculosis vaccine cannot be clinically effective. While this conclusion has been recently challenged by Opie, it is still the accepted belief of most immunologists. The studies by Sabin and her co-workers seemed to confirm this belief. Different chemical fractions of tubercle bacilli were found to produce widely different local and humoral reactions in experimental animals, none of which could be regarded as a complete immunity. Following Burky's [2] demonstration of synergic effects with mixed antigens, the Rockefeller Institute immunologists began a study of the possibility of sensitizing or immunizing animals with mixtures of two or more of their earlier antigenic fractions. Their initial success is from a mixture of ordinary tuberculoproteins and tuberculophosphatides. Confirming the work of other investigators they found that guinea pigs can be sensitized by repeated intradermal injections with tuberculoprotein but that animals so sensitized will not react to the routine tuberculin test. Guinea pigs sensitized by multiple intradermal injections with tuberculophosphatide also show atypical sensitivity, since they do not exhibit the Koch phenomenon. The phosphatide and tuberculoproteins, however, apparently supplement each other in antituberculosis immunity. Following intradermal injections with a mixture of these two antigenic factions, routine diagnostic reactions are given by the sensitized guinea pigs that are qualitatively and quantitatively identical with those of tuberculous animals. Whether or not this synergic sensitivity is accompanied by an equally effective synergic immunity has not yet been determined. Even though a full immunity is not obtained with the present antigenic mixture, this work represents a distinct advance in the basic theory of immunity in tuberculosis.

ORGANIZATION SECTION

THE ST. LOUIS SESSION

AMERICAN MEDICAL ASSOCIATION, NINETIETH ANNUAL SESSION
ST. LOUIS, MO., MAY 15-19, 1939

OFFICIAL CALL

TO THE OFFICERS, FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The ninetieth annual session of the American Medical Association will be held in St. Louis, May 15-19, 1939.

The House of Delegates will convene at 10 a. m., Monday, May 15. In the House the representation of the various constituent associations for 1938, 1939 and 1940 is as follows:

Alabama	2	New Hampshire	1
Arizona	1	New Jersey	4
Arkansas	2	New Mexico	1
California	7	New York	19
Colorado	2	North Carolina	2
Connecticut	2	North Dakota	1
Delaware	1	Ohio	7
District of Columbia	1	Oklahoma	2
Florida	2	Oregon	1
Georgia	3	Pennsylvania	11
Idaho	1	Rhode Island	1
Illinois	9	South Carolina	2
Indiana	4	South Dakota	1
Iowa	3	Tennessee	3
Kansas	2	Texas	6
Kentucky	3	Utah	1

The fifteen scientific sections of the American Medical Association, the Medical Corps of the Army, the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each.

The Scientific Assembly of the Association will open with the general meeting, to be held at 8 p. m., Tuesday, May 16. The sections will meet Wednesday, Thursday and Friday, May 17, 18 and 19, as follows:

CONVENING AT 9 A. M., THE SECTIONS ON

- Practice of Medicine.
- Obstetrics and Gynecology.
- Laryngology, Otology and Rhinology.
- Pathology and Physiology.
- Preventive and Industrial Medicine and Public Health.
- Urology.
- Orthopedic Surgery.
- Miscellaneous Topics: Session on Anesthesia.

CONVENING AT 2 P. M., THE SECTIONS ON

- Surgery, General and Abdominal.
- Ophthalmology.
- Pediatrics.
- Pharmacology and Therapeutics.
- Nervous and Mental Diseases.
- Dermatology and Syphilology.
- Gastro-Enterology and Proctology.
- Radiology.

The Registration Department will be open from 8:30 a. m. until 5:30 p. m., Monday, Tuesday, Wednesday and Thursday, May 15, 16, 17 and 18, and from 8:30 a. m. to 12 noon, Friday, May 19.

IRVIN ABELL, President.
H. H. SHOULDERS, Speaker, House of Delegates.
OLIN WEST, Secretary.

MEMBERS OF THE HOUSE OF DELEGATES

A Preliminary Roster of the Legislative Body of the American Medical Association

The list of members of the House of Delegates for the session is incomplete, as a number of the state associations are yet to hold their meetings at which delegates will be elected. The following is a list of the holdover members of the House of Delegates and of the newly elected members who have been reported to the Secretary in time to be included:

STATE DELEGATES

ALABAMA
J. N. Baker, Montgomery.
A. A. Walker, Birmingham.

ARIZONA

ARKANSAS
Edward E. Barlow, Dermott.
William R. Brooksher, Fort Smith.

CALIFORNIA
Elbridge J. Best, San Francisco.
Lyell C. Kinney, San Diego.
J. P. Nuttall, Santa Monica.
Edward M. Pallette, Los Angeles.
George G. Reinle, Oakland.
Robert A. Peers, Colfax.
William R. Molony Sr., Los Angeles.

COLORADO
John Andrew, Longmont.
Walter W. King, Denver.

CONNECTICUT
George Blumer, New Haven.
Walter R. Steiner, Hartford.

DELAWARE
William H. Speer, Wilmington.

DISTRICT OF COLUMBIA
Henry Cook Macatee, Washington.

FLORIDA
Herbert L. Bryans, Pensacola.

GEORGIA
Olin H. Weaver, Macon.
William H. Myers, Savannah.
Charles W. Roberts, Atlanta.

IDAHO
E. N. Roberts, Pocatello.

ILLINOIS
G. Henry Mundt, Chicago.
R. K. Packard, Chicago.
Charles J. Whalen, Chicago.
John J. Pflock, Chicago.
E. S. Hamilton, Kankakee.

INDIANA
Don F. Cameron, Fort Wayne.
F. S. Crockett, LaFayette.
George R. Dillinger, French Lick.
H. G. Hamer, Indianapolis.

IOWA
Thomas F. Thornton, Waterloo.
V. L. Treynor, Council Bluffs.

KANSAS
Howard L. Snyder, Winfield.

KENTUCKY
Virgil E. Simpson, Louisville.
Elmer L. Henderson, Louisville.
Arthur T. McCormack, Louisville.

LOUISIANA
James O. Graves, Monroe.
A. A. Herold, Shreveport.

MAINE
William A. Ellingwood, Rockland.

MARYLAND
Alfred T. Gundry, Catonsville.
Harvey B. Stone, Baltimore.

MASSACHUSETTS
David D. Scannell, Boston.
Dwight O'Hara, Waltham.
Charles E. Mongan, Somerville.
Walter G. Phippen, Salem.
Richard H. Miller, Boston.
Edmond F. Cody, New Bedford.
John M. Birnie, Springfield.

MICHIGAN
L. G. Christian, Lansing.
Henry A. Luce, Detroit.
T. K. Gruber, Eloise.
Frank E. Reeder, Flint.
Claude R. Keyport, Grayling.

MINNESOTA
E. A. Meyerding, St. Paul.
W. F. Braasch, Rochester.
W. A. Coventry, Duluth.

MISSISSIPPI
Harvey F. Garrison, Jackson.
Felix J. Underwood, Jackson.

MISSOURI
A. R. McComas, Sturgeon.
H. L. Kerr, Crane.

MONTANA
James H. Irwin, Great Falls.

NEBRASKA
Roy W. Fouts, Omaha.
Karl S. J. Hohlen, Lincoln.

NEVADA
Horace J. Brown, Reno.

NEW HAMPSHIRE
Deering G. Smith, Nashua.

NEW JERSEY
Andrew F. McBride, Paterson.
Wells P. Eagleton, Newark.
Hilton S. Read, Ventnor.

NEW MEXICO
H. A. Miller, Clovis.

NEW YORK
Samuel J. Kopetzky, New York.
Frederic E. Sondern, New York.
James M. Flynn, Rochester.
Thomas A. McGoldrick, Brooklyn.
Charles H. Goodrich, Brooklyn.
George M. Fisher, Utica.
Peter Irving, New York.
Adolph G. DeSanctis, New York.

NORTH CAROLINA
M. L. Stevens, Asheville.

NORTH DAKOTA
A. P. Nachtwey, Dickinson.

OHIO
Charles W. Stone, Cleveland.
Ben R. McClellan, Xenia.
Carl R. Steinke, Akron.
E. R. Brush, Zanesville.

OKLAHOMA
W. Albert Cook, Tulsa.

OREGON
John H. Fitzgibbon, Portland.

PENNSYLVANIA
Howard C. Frontz, Huntingdon.
J. Newton Hunsberger, Norristown.
Herbert B. Gibby, Wilkes-Barre.
Frank P. Lytle, Birdsboro.
Curtis C. Mechling, Pittsburgh.
Charles G. Strickland, Erie.
Francis F. Borzell, Philadelphia.
Charles A. E. Codman, Philadelphia.
Walter F. Donaldson, Pittsburgh.
Charles Falkowsky Jr., Scranton.
Samuel P. Mengel, Wilkes-Barre.

RHODE ISLAND
Guy W. Wells, Providence.

SOUTH CAROLINA
Joseph H. Cannon, Charleston.

SOUTH DAKOTA
John R. Westaby, Madison.

TENNESSEE
H. B. Everett, Memphis.
H. H. Shoulders, Nashville.

TEXAS
J. W. Burns, Cuero.
A. A. Ross, Lockhart.
E. H. Cary, Dallas.
Holman Taylor, Fort Worth.
Felix P. Miller, El Paso.
S. E. Thompson, Kerrville.

UTAH
John Z. Brown, Salt Lake City.

VERMONT
Benjamin F. Cook, Rutland.

VIRGINIA
Walter B. Martin, Norfolk.
Carrington Williams, Richmond.
Wright Clarkson, Petersburg.

WASHINGTON
J. H. O'Shea, Spokane.
Raymond L. Zech, Seattle.

WEST VIRGINIA
Ivan Fawcett, Wheeling.
Walter E. Vest, Huntington.

WISCONSIN
Joseph F. Smith, Wausau.
Stephen E. Gavin, Fond du Lac.
James C. Sargent, Milwaukee.

WYOMING
George P. Johnston, Cheyenne.

ALASKA

HAWAII
Forrest J. Pinkerton, Honolulu.

ISTHMIAN CANAL ZONE
Lewis B. Bates, Ancon.

PHILIPPINE ISLANDS

PUERTO RICO
J. H. Font, San Juan.

DELEGATES FROM THE SECTIONS AND GOVERNMENT SERVICES

PRACTICE OF MEDICINE
J. E. Paullin, Atlanta, Ga.

SURGERY, GENERAL AND ABDOMINAL
Fred W. Rankin, Lexington, Ky.

OBSTETRICS AND GYNECOLOGY
George Gray Ward, New York.

OPHTHALMOLOGY
Arthur J. Bedell, Albany, N. Y.

LARYNGOLOGY, OTOLOGY AND RHINOLOGY
Burt R. Shurly, Detroit.

PEDIATRICS
William Weston, Columbia, S. C.

PHARMACOLOGY AND THERAPEUTICS
Cary Eggleston, New York.

PATHOLOGY AND PHYSIOLOGY
L. W. Larson, Bismarck, N. D.

NERVOUS AND MENTAL DISEASES
T. B. Throckmorton, Des Moines, Iowa.

DERMATOLOGY AND SYPHILOLOGY
Clyde L. Cummer, Cleveland.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH
Stanley H. Osborn, Hartford, Conn.

UROLOGY
H. C. Bumpus, Pasadena, Calif.

ORTHOPEDIC SURGERY
Willis C. Campbell, Memphis, Tenn.

GASTRO-ENTEROLOGY AND PROCTOLOGY
Curtice Rosser, Dallas, Texas.

RADIOLOGY
E. H. Skinner, Kansas City, Mo.

UNITED STATES ARMY
George C. Dunham, Washington, D. C.

UNITED STATES NAVY
Henry L. Dollard, Great Lakes, Ill.

UNITED STATES PUBLIC HEALTH SERVICE
Warren F. Draper, Washington, D. C.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION, 1938-1939

PRESIDENT—Irvin Abell, Louisville, Ky.

PRESIDENT-ELECT—Rock Sleyster, Wauwatosa, Wis.

VICE PRESIDENT—Howard Morrow, San Francisco.

SECRETARY AND GENERAL MANAGER—Olin West, Chicago.

TREASURER—Herman L. Kretschmer, Chicago.

SPEAKER, HOUSE OF DELEGATES—H. H. Shoulders, Nashville, Tenn.

VICE SPEAKER, HOUSE OF DELEGATES—R. W. Fouts, Omaha.

EDITOR—Morris Fishbein, Chicago.

BUSINESS MANAGER—Will C. Braun, Chicago.

BOARD OF TRUSTEES—Roger I. Lee, Boston, 1939; Allen H. Bunce, Atlanta, Ga., 1939; Ralph A. Fenton, Portland, Ore., 1940; James R. Bloss, Huntington, W. Va., 1940; Thomas S. Cullen, Baltimore, 1941; Arthur W. Booth, Chairman, Elmira, N. Y., *1942*; R. L. Sensenich, South Bend, Ind., 1942; Austin A. Hayden, Secretary, Chicago, 1943; Charles B. Wright, Minneapolis, 1943.

JUDICIAL COUNCIL—Edward R. Cunniffe, New York, 1939; G. E. Follansbee, Chairman, Cleveland, 1940; Walter F. Donaldson, Pittsburgh, 1941; John W. Burns, Cuero, Texas, 1942; John H. O'Shea, Spokane, Wash., 1943; Olin West, Secretary, ex officio, Chicago.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS—R. L. Wilbur, Chairman, Stanford University, Calif., 1939; John H. Musser, *New Orleans, 1940*; *Fred Moore, Des Moines,* Iowa, 1941; Reginald Fitz, Boston, 1942; Fred W. Rankin, Lexington, Ky., 1943; *Charles Gordon Heyd, New York, 1944*; Frank H. Lahey, Boston, 1945; W. D. Cutter, Secretary, Chicago.

COUNCIL ON SCIENTIFIC ASSEMBLY—J. Gurney Taylor, Milwaukee, Wis., 1939; A. A. Walker, Birmingham, Ala., 1940; J. C. Flippin,* Charlottesville, Va., 1941; Clyde L. Cummer, Cleveland, 1942; James E. Paullin, Chairman, Atlanta, Ga., 1943, and ex officio, the President-Elect, the Editor and the Secretary of the Association.

* Deceased.

COUNCIL ON PHARMACY AND CHEMISTRY (Standing Committee of Board of Trustees)—Morris Fishbein, Chicago, 1940; G. W. McCoy, Washington, D. C., 1940; Perrin H. Long, Baltimore, 1940; Elmer M. Nelson, Washington, D. C., 1940; Torald Sollmann, Chairman, Cleveland, 1941; W. C. Rose, Urbana, Ill., 1941; E. L. Sevringhaus, Madison, Wis., 1941; E. M. K. Geiling, Chicago, 1942; W. W. Palmer, New York, 1942; S. W. Clausen, Rochester, N. Y., 1942; R. A. Hatcher, New York, 1943; E. E. Irons, Chicago, 1943; H. N. Cole, Cleveland, 1943; Stuart Mudd, Philadelphia, 1943; J. Howard Brown, Baltimore, 1944; C. W. Edmunds, Ann Arbor, Mich., 1944; David P. Barr, St. Louis, 1944; Paul Nicholas Leech, Secretary, Chicago.

COUNCIL ON PHYSICAL THERAPY (Standing Committee of Board of Trustees)—Howard T. Karsner, Cleveland, 1940; Frank R. Ober, Boston, 1940; Frank D. Dickson, Kansas City, Mo., 1940; A. U. Desjardins, Rochester, Minn., 1941; H. B. Williams, New York, 1941; Frank H. Krusen, Rochester, Minn., 1941; Ralph Pemberton, Philadelphia, 1942; Harry E. Mock, Chairman, Chicago, 1942; Anthony C. Cipollaro, New York, 1942; W. E. Garrey, Nashville, Tenn., 1943; W. W. Coblentz, Washington, D. C., 1943; John S. Coulter, Chicago, 1943; Olin West, ex officio, Chicago; Morris Fishbein, ex officio, Chicago; Howard A. Carter, Secretary, Chicago.

COUNCIL ON FOODS (Standing Committee of Board of [illegible] neapolis, Chicago, Minn., 1941; Howard B. Lewis, Ann Arbor, Mich., 1941; J. S. McLester, Birmingham, Ala., 1941; Philip C. Jeans, Iowa City, 1942; Lydia Mary Swartz Rose, New York, 1942; J. Roberts, Chicago, 1943; George R. Cowgill, New Haven, Conn., 1943; C. S. Ladd, Bismarck, N. D., 1944; Tom D. Spies, Cincinnati, 1944; Franklin C. Bing, Secretary, Chicago.

COUNCIL ON INDUSTRIAL HEALTH (Standing Committee of Board of Trustees)—Stanley J. Seeger, Chairman, Milwaukee, Wis.; Harvey Bartle, Philadelphia; L. D. Bristol, New York; Warren F. Draper, Washington, D. C.; Leroy U. Gardner, Saranac Lake, N. Y.; H. H. Kessler, Newark, N. J.; A. J. Lanza, New York; A. D. *Lazenby*, Baltimore; Earl D. Osborne, Buffalo; C. W. Roberts, Atlanta, Ga.; C. D. Selby, Detroit; C. M. Peterson, Secretary, Chicago.

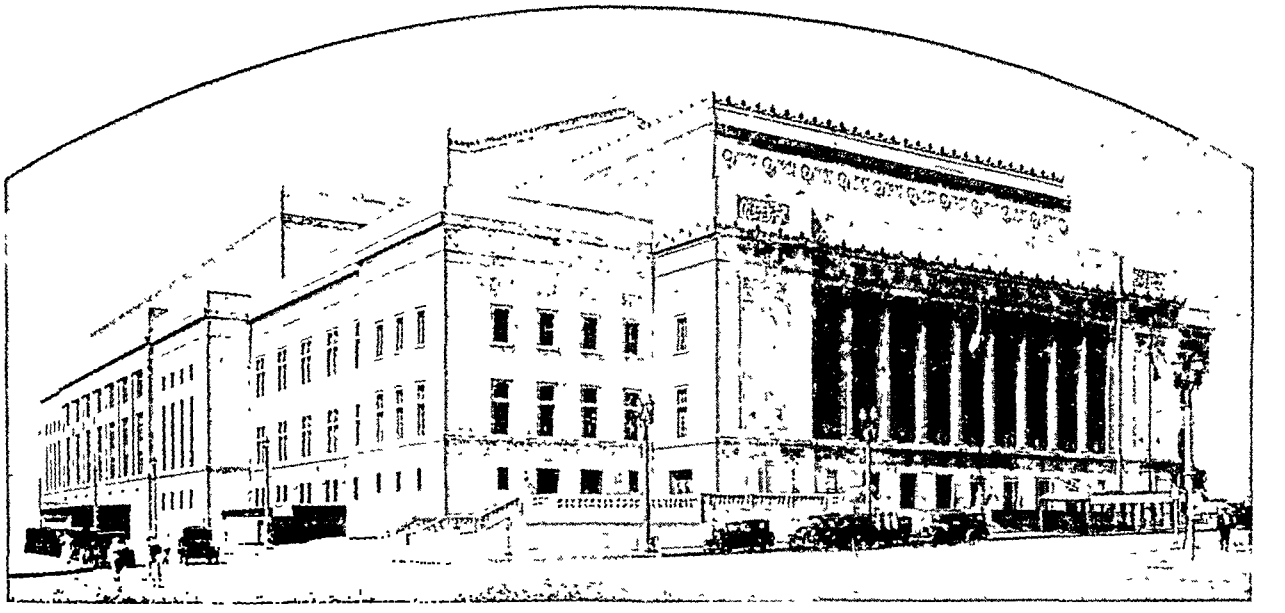
COMMITTEE ON SCIENTIFIC EXHIBIT—Allen H. Bunce, Chiarman, *Atlanta*, Ga.; Roger I. Lee, Boston; Thomas S. Cullen, Baltimore; Thomas G. Hull, Director, Chicago. Advisory Committee—D. Chester Brown, Danbury, Conn.; George Blumer, New Haven, Conn.; Paul J. Hanzlik, San Francisco; Ludvig Hektoen, Chicago; Urban Maes, New Orleans; Eben J. Carey, Milwaukee; James P. Leake, Washington, D. C.

BUREAU OF LEGAL MEDICINE AND LEGISLATION—W. C. Woodward, Director, Chicago.

BUREAU OF HEALTH EDUCATION—W. W. Bauer, Director, Chicago.

BUREAU OF INVESTIGATION—Paul C. Barton, Director, Chicago.

BUREAU OF MEDICAL ECONOMICS—R. G. Leland, Director, Chicago.



CHEMICAL LABORATORY—Paul Nicholas Leech, Director, Chicago.

LIBRARY—Marjorie *Hutchins* Moore, Librarian, Chicago.

ST. LOUIS, THE HUB OF THE NATION, WELCOMES YOU!

Famous for its magnificent buildings, parks and boulevards, St. Louis has steadily advanced into metropolitan areas since the French pioneers landed in 1764, at what is now the foot of Walnut Street. Like the landing of the Pilgrim Fathers, the coming of the "First Thirty," as this band became known, marked the beginning of a great empire. On the morning of February 16, August Chouteau led his men to the plateau overlooking the river. The blows of axes sounded through the woods and the building of St. Louis began.

Within three years the colonists had established fur trading monopolies with the twenty-eight principal Indian nations. Each year saw the city's influence widen. St. Louis became the starting point of expeditions in all directions, some military, to establish forts; some scientific, to explore, and others to establish communities to open commercial avenues. One of these was the Lewis and Clark expedition in 1804, opening the Northwest

MUNICIPAL AUDITORIUM WHERE THE ANNUAL SESSION WILL BE HELD

The Frenchmen of St. Louis also paved the way for the American occupation of Louisiana. A branch of the Chouteau family founded Kansas City. Robidoux of St. Louis established St. Joseph. One of the Menards founded Galveston.

Fully a hundred western cities and towns owe their beginning to St. Louisans.

The year 1811 marked the appearance of the Mississippi steamboat. Five years later the first steamboat came up the river, and for fifty years river trade grew by leaps and bounds.

St. Louis today is one of the most modern cities in America. Geographically it meets you half way, and in hospitality it goes the whole way. Visitors will enjoy seeing the Art Museum, the Cahokia Mounds, Chain of Rocks Park, the Confederate Memorial, the Dent House, Eads Bridge, Forest Park, Grant's Log Cabin, Jefferson Memorial, the Lindbergh Trophies, the Old Court House, "Ol' Man River," Shaw's Garden, the St. Louis Municipal Airport, the Zoological Gardens and many other attractions.

THE PLAZA

Some of the principal public buildings in St. Louis are grouped about a fine plaza, developed after long term planning and made possible by bond issues exceeding $100,000,000. This most unusual group of new buildings comprises the Municipal Auditorium, the Civil Courts Building, the federal court and custom house, and the $1,000,000 Soldier Memorial Building; facing the Plaza also are the City Hall and Municipal Courts Building, while nearby are the Public Library, the new post office and the new police headquarters. St. Louis has become architecturally renowned also through its thirty-one story telephone building, the huge railway exchange building, the majestic new cathedral and the Scottish Rite Cathedral. It was among the first large American cities to adopt city planning and has not only its plaza but widened boulevards, sunken gardens and other examples of serene beauty in the downtown section.

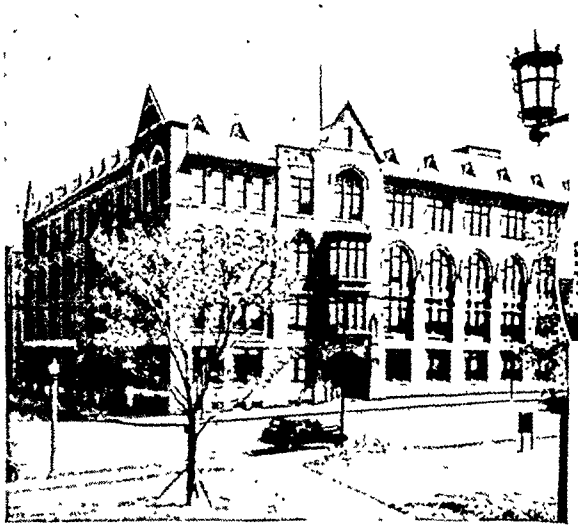
THE MUNICIPAL AUDITORIUM

The new $6,000,000 St. Louis auditorium, where the sessions will be held, makes an impression of massive dignity and power as one approaches across the expansive plaza of this great temple dedicated to the people. Within its walls softly padded avenues lead into three large assembly units: the great opera house, the stupendous arena and the expansive exposition hall. Here is the most complete convention building in the world. From the opera house stage, a loud speaker system casts even the weakest voice throughout the building. When the 30 ton fireproof steel curtain between the opera house and the arena is raised, the two enormous areas become one large amphitheater, seating 16,000 people.

No necessary detail for the large assembly was overlooked in the planning of this auditorium. Conveniently woven into the larger pattern are smaller assembly halls with stages, committee rooms, offices, a cafeteria, a refreshment bar, a ticket lobby and a foyer. The entire building is air conditioned. A million cubic feet of fresh air a minute comes into fourteen fan rooms and is conveyed to every part of the building at the rate of 30 cubic feet a minute per person. The opera house seats are richly upholstered over box springs. Audiences and speakers alike enjoy the restfulness that pure air, diffused lighting and dignified furnishings provide.

The Municipal Auditorium is on Market Street between Twelfth Boulevard and Eighteenth Street, three blocks from the Union Depot and within walking distance of many of the best hotels. Ample parking facilities are adjacent. The entrance itself is spacious, with its ticket windows and space for registration booths. A broad stairway leads from both ends to the Grand Lobby, as elegant as a king's palace, with marble columns, gilded ceiling, opal flashed chandeliers, velvet drapes and deep carpets, a restful place indeed to visit with old friends. Four

doors open from the Grand Lobby into a balcony which affords a view of the enormous combined assembly halls.



Two of the four smaller assembly rooms are on the third flour, each with a capacity for 800 people. Stairways, elevators and ramps make it easy to reach any of the four flours and the numerous halls and committee rooms. On the ground floor below the convention hall is the Exposition Hall, a spacious area adaptable to almost any type of exhibit.

THE ZOO

Internationally famous is the St. Louis Zoo. Experts come to St. Louis from elsewhere in this country and from abroad to study the unusual arrangements by which animal dens have been transformed into near-to-nature haunts.

Within the zoo's 77 acres in Forest Park are more than 1,964 mammals, birds, fish, reptiles and amphibians. Here are the "cageless" bear pits, the new monkey house, the largest steel-enclosed bird cage in the world, the swan lakes, which also serve as a sanctuary for wild ducks and geese on their migrations, the new reptile house, and Peacock Valley, with its chain of thirteen lakes teeming with aquatic life.

Steel and concrete structures house lions, tigers, leopards, elephants, hippopotamuses and other creatures.

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE

WASHINGTON UNIVERSITY SCHOOL OF MEDICINE

THE BOTANICAL GARDEN

The Missouri Botanical Garden (Shaw's Garden), which ranks second only to the famous Kew Gardens of England, contains the largest collection of plant life in the Western Hemisphere. It comprises a city garden of about 75 acres, an out of town extension of more than 1,600 acres, and a tropical extension at Balboa, Panama. More than 11,000 species of plants from all parts of the globe may be seen there.

One of the best botanical libraries in the country, one of the largest herbariums in the United States, laboratories for scientific work and a school for gardening combine the features of a pleasure ground with the facilities of an institution of research. The garden was established by the will of Henry Shaw and is maintained entirely by his endowment. The orchid collection is said to be the finest on the American continent. The garden is open daily to the public, and admission is free.

ST. LOUIS AS A MEDICAL CENTER

While attaining success in industry, St. Louis at the same time has developed into one of the medical centers of the United States, having unusual facilities for the care of the sick, for medical research and for the instruction of medical students at two great medical schools.

WASHINGTON UNIVERSITY SCHOOL OF MEDICINE

By the union in 1899 of two medical schools, Washington University School of Medicine was founded. Fifteen years later it moved from Eighteenth and Locust streets to new buildings at Euclid Avenue and Kingshighway Boulevard, facing Forest Park. Affiliated with it are the Barnes Hospital, St. Louis Children's Hospital, McMillan Eye, Ear, Nose and Throat Hospital, and Oscar Johnson Institute. Further teaching facilities are afforded by the St. Louis City Hospital, including the City Isolation Hospital and the City Sanitarium. The Washington University Dispensary serves as an outpatient clinic. Washington University School of Medicine has also museums in the various departments. Recently a collection of anatomic specimens prepared with unusual skill was purchased. Adjoining the main reading room of the excellent library is the famous Beaumont collection of manuscripts, letters and other material of the pioneer American physiologist, presented by his granddaughter, the late Lilly Beaumont Irwin.

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE

Established in 1837 in a small hospital on Washington Avenue, the St. Louis University School of Medicine ten years later moved to its own building at Seventh and Clark avenues. Eight years later the affiliation between the medical school and the university was severed. The medical school, then independent, was known as the St. Louis Medical College. Beaumont Medical College, organized in 1886, and the Marion Sims School of Medicine, organized in 1890, combined in 1901 into the Marion Sims-Beaumont Medical College. These medical schools merged in 1901, and in 1903 St. Louis University assumed control of them. The reorganization provided not only full time department heads for the fundamental departments but in 1927 the present group of medical buildings on Compton Hill, at Grand Boulevard and Caroline Street. Here the University Hospital embraces the Firmin Desloge Hospital, St. Mary's Hospital and Mount St. Rose Sanitarium. The educational and medical activities of the Sisters of St. Mary have been placed under the control of the university. Teaching facilities are furnished also by the Alexian Brothers', St. Anthony's and St. John's hospitals, the staffs of which are appointed by the university; associated also are St. Ann's Maternity Hospital, St. Ann's Foundling Society and the St. Louis Obstetric Dispensary. Additional teaching facilities are afforded by the St. Louis City Hospital.

OTHER ST. LOUIS HOSPITALS

In addition to the hospitals connected with the two medical schools, there are the Bethesda General Hospital, Barnard Free Skin and Cancer Hospital, Christian Hospital, De Paul Hospital, Jewish Hospital, Lutheran Hospital, Missouri Baptist Hospital, Missouri Pacific Hospital, St. Louis City Hospital No. 1, St. Luke's Hospital, St. Ann's Maternity Hospital, Evangelical Deaconess Home and Hospital, Frisco Employees' Hospital, Shriners' Hospital for Crippled Children and the United States Marine Hospital.

THE ST. LOUIS MEDICAL SOCIETY

The St. Louis Medical Society, founded in 1836, now occupies a new, beautiful $400,000 home at 3839 Lindell Boulevard, constructed especially for the society after months of ceaseless effort by committees and other members to obtain the funds. Here a large lounge offers relaxation from the cares of practice and a congenial spirit for informal conferences. On the walls are tablets for Bernard Farrar, the first president of the society, William Beaumont, president in 1841, and John T. Hodgen, president in 1876. The Bartscher room, a memorial to Dr. Hugh Bartscher from his mother, who left $41,000 for this purpose, contains historical collections, rare books, medals and art exhibits. The Glasgow reading room is named in honor of Drs. William C. Glasgow and Frank A. Glasgow, whose sister, Mrs. Newton R. Wilson, gave $50,000 to the building fund. About 300 persons visit this reading room each month. Two librarians are in constant attendance. The library on the second floor contains more than 30,000 volumes and receives 325 current journals. A collection of about 800 rare medical books and pictures, given by the late James M. Ball, is on exhibit. The auditorium will accommodate 700 persons, and there are smaller meeting rooms, a large dining room and rooms for entertainment. The St. Louis Medical Society has 1,000 active members. It publishes a weekly bulletin and has numerous committees studying problems of public welfare and public health as well as economic and scientific problems. It sponsors weekly broadcasts on public health on time allotted through the courtesy of a local broadcasting station.

FOREST PARK

In Forest Park St. Louis has one of the largest fully developed parks in the United States, comprising nearly 1,381 acres, so spacious that natural features may be combined with formal landscaping, artificial lagoons and lakes, fountains and aquatic plants. In addition to the features already briefly described there are three golf courses, twenty-five baseball diamonds, thirty-eight tennis courts and soccer fields, 200 Japanese cherry trees and the city art museum, which was a feature of the Louisiana Purchase Exposition in 1904, at the close of which the $1,000,000 building was presented to the city.

The Jewel Box, operated in conjunction with the eighteen greenhouses maintained by the park department, is internationally famous for its exhibits of plants and flowers and reproductions of foreign gardens. Last year three new rosariums were created, one in front of the Jewel Box, which when lighted at night shows the splendor of thousands of roses.

The general offices of the Division of Parks and Recreation are in room 330, Municipal Courts Building, Fourteenth and Market streets.

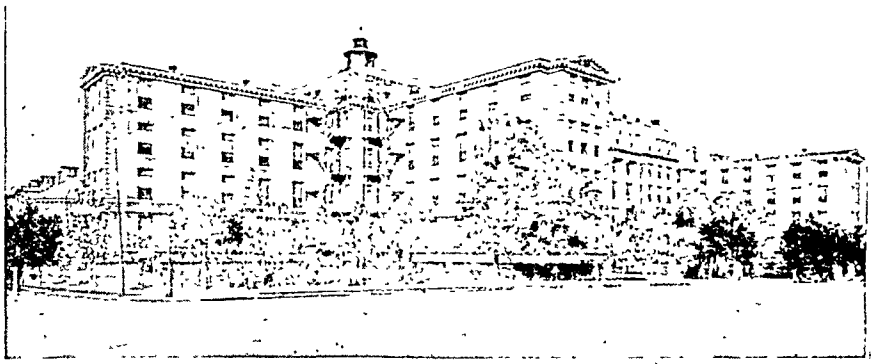
SUMMER OPERA OUTDOORS

St. Louis is known the world over for its summer opera, conducted by the Municipal Theater Association in an open air amphitheater in Forest Park a short distance from the municipal auditorium. This summer will see the twenty-first season. Since 1919 nearly 10,000,000 people have enjoyed 1,374 performances, including five world premiers and four American premiers. Ten thousand seats are available at reasonable prices and there are 1,700 free seats. About 30,000 reserved seats are distributed annually to the underprivileged through more than 100 welfare agencies.

The stage is flanked by two oak trees 70 feet high, beside which are illuminated towers. Almost 1,000 guarantors have invested a total of $100,000 to insure each season against loss, but never has a guarantor lost a penny. This opera is fully divorced from the old idea that opera must be supported by gifts from the rich or from the state; it is a triumph of democratic ideals. Nature designed the open auditorium and man arranged it so that every one has an unobstructed view. There is parking space for 5,000 automobiles within two minutes' walking distance of the entrance.

JEFFERSON MEMORIAL

Erected as a memorial to Thomas Jefferson by the federal government, the city and the Louisiana Purchase Exposition and standing on the site of the main entrance to the exposition,



HOME OF ST. LOUIS MEDICAL SOCIETY BUILDING ON LINDELL NEAR VANDEVENTER

Jefferson Memorial is a combination of a museum, library, statue, archway and community center and thus is a fitting monument to one of the most democratic citizens in American history. Of supreme interest is the famous Lindbergh collection. Colonel Lindbergh chose the Jefferson Memorial, with the Missouri Historical Society as custodian, as the permanent resting place of the trophies and mementos which came to him in connection with his flight in the *Spirit of St. Louis* across the Atlantic and his tour of Mexico, Central America and South America. In the memorial also are relics of the Mound Builders, curios of Indian tribes, original manuscripts of the French and Spanish days in Missouri, relics of the pioneers and of the Revolutionary, Mexican, Spanish-American and World wars, ancient records of Missouri courts, the third largest collection of Jefferson manuscripts in the country, a large portion of the manuscripts of the Hamilton-Burr controversy, and records of the Lewis and Clark Expedition.

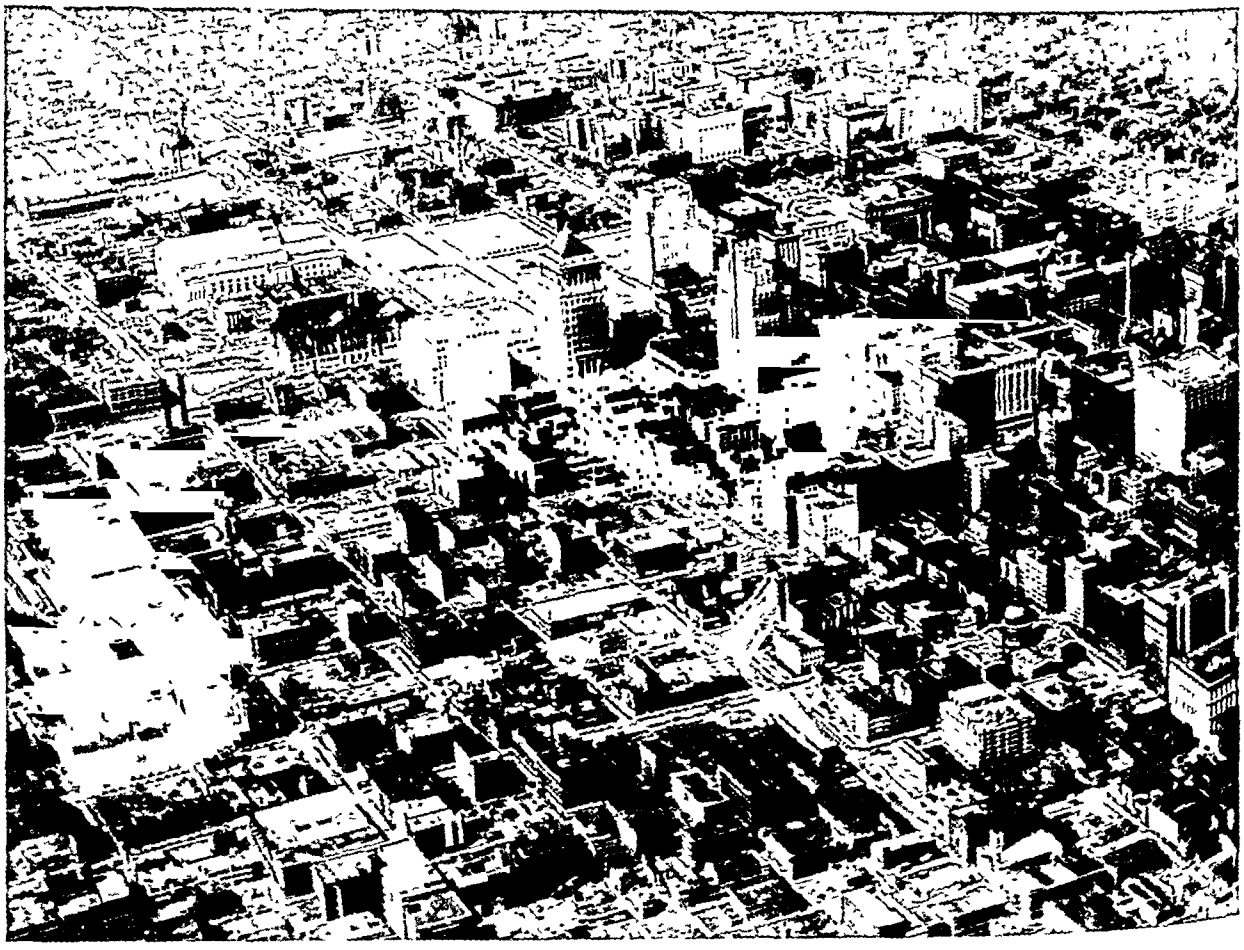
ST. JOHN'S HOSPITAL, 307 S. EUCLID AVE.

HISTORICAL LANDMARKS

St. Louis is rich in history, traditions and landmarks of dauntless men. In the Lucas Market Place Ulysses S. Grant once sold cord wood. Here is the home in which he married Julia Dent. At the door of the Old Court House, the scene of the Dread Scott trial, there still stands the auction block on which slaves were sold. The oldest building in the city is Rock House, on the river front at Chestnut Street, near where the "first thirty" landed in 1764; a few blocks away is the cathedral on the site of which mass was first celebrated in St. Louis. There is the site of the old Government House, where the Louisiana territory was transferred from France to the United States, and the home of William Clark, the explorer.

TRANSPORTATION

Railroad Rates to St. Louis



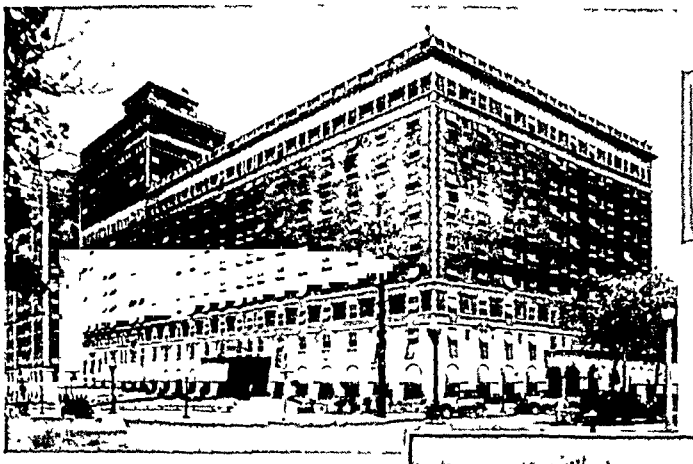
Because of the reduction in one way fares effective June 1, 1936, for travel in sleeping and parlor cars, which closely approximates the former convention fare basis, the use of convention fares has been discontinued in the territories of the Central Passenger, Trunk Line, New England, Southern and Southwestern Passenger Associations.

In the territory of the Southern Passenger Association, daily round trip fares are in effect to St Louis on the basis of 2½ cents a mile in each direction with limit of six months in addition to date of sale going and returning the same route, also via diverse routes, tickets being honored in sleeping or parlor cars on payment of charges for space occupied In addition, reduced fares are in effect on a slightly lower basis from certain points in the extreme western part of the territory to St Louis for tickets bearing limit of thirty days in addition to date of sale. These fares are subject to change but in all probability these or comparable fares will be available.

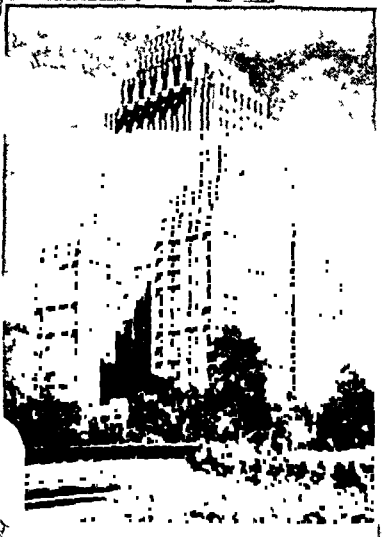
In the territory of the Southwestern Passenger Association, for travel in sleeping or parlor cars, thirty day limit fares are on the basis of fare and one half or 2¼ cents a mile in each direction. In case a longer limit than thirty days is desired, tickets at slightly higher fares are available. In addition, round trip tickets good for transportation in coaches only may be obtained at a fare of 5 per cent less than double the one way 2 cents a mile coach fare, and these tickets have a limit of thirty days in addition to date of sale. These tickets may be obtained without the presentation of credentials

In the territory of the Trans-Continental and Western Passenger Associations, low round trip fares, for which no certificates of any kind will be necessary, will be in effect daily for travel in sleeping and parlor cars, on payment of the usual charges for space occupied Low intermediate class fares, good for transportation in tourist sleeping cars, will also be available on payment of charges for space occupied

All members who expect to attend the session are urged to confer with their home ticket agents, who will be able to give them more specific information regarding fares and routes



AIR VIEW OF DOWNTOWN ST. LOUIS



Air Travel

By air, St Louis is just a few hours from most important cities in the United States, Canada and Mexico, and no more than overnight from the most distant. Sleeper accommodations are available on overnight journeys on most of the transcontinental services. Your nearest Airline Ticket Office, Travel Bureau, Hotel Transportation Desk or Western Union or Postal Telegraph Office will gladly arrange your itinerary.

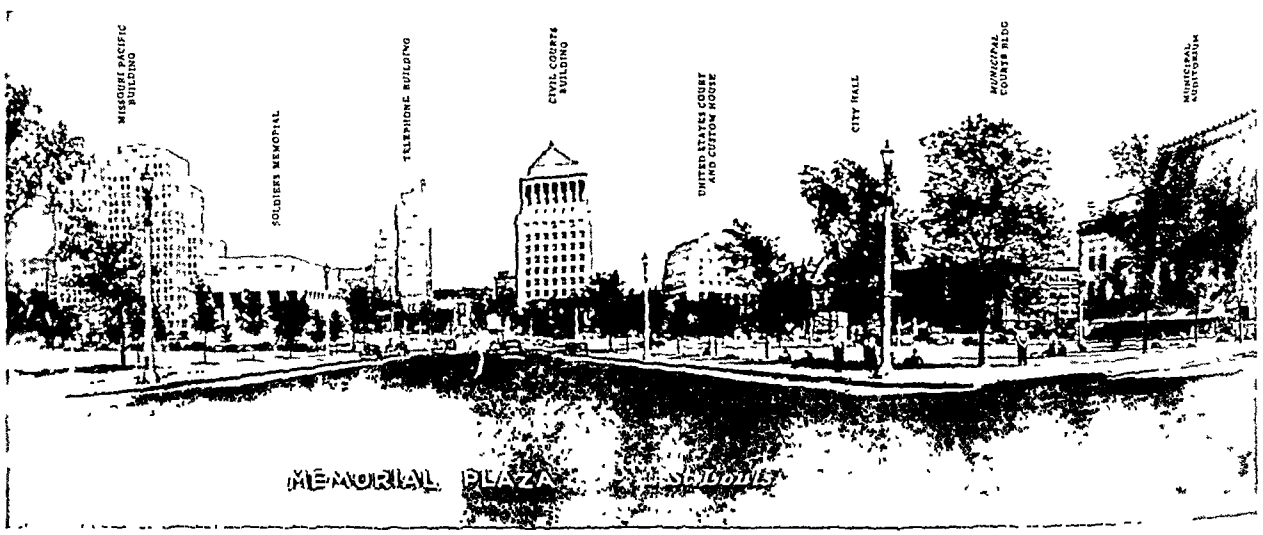
REGISTRATION

The Bureau of Registration will be located in the Municipal Auditorium, Market Street, between Fourteenth and Fifteenth streets. Members of the Subcommittee on Registration of the Local Committee on Arrangements will be on hand to assist those who desire to register. A branch postoffice in charge of government postoffice officials will be available for visitors, and an information bureau will be operated in connection with the Bureau of Registration.

Who May Register

Only Fellows, Affiliate, Associate and Honorary Fellows and Invited Guests may register and take part in the work of the sections. Fellows of the Scientific Assembly are those who have, on the prescribed form, applied for Fellowship, subscribed to THE JOURNAL and paid their Fellowship dues for the current year The annual Fellowship dues provide a subscription to THE JOURNAL for one year. Fellowship cards are sent to all Fellows after payment of annual dues, and these cards should be presented at the registration window Any



Suggestions That Will Facilitate Registration

Fellows should fill out completely the spaces on both sections of the front of the *white* registration card, which will be found on the tables in front of the Registration Bureau

Physicians who desire to qualify as Fellows should fill out completely the spaces on both sections of the front of the *blue* registration card and sign the application on the back These cards will be found on the tables.

Entries on the registration cards should be written plainly or printed, as the cards are given to the printer to use as "copy" for the *Daily Bulletin*, published on Tuesday, Wednesday, Thursday and Friday of the week of the session

Fellows who have their pocket cards with them can be registered with little or no delay. They should present the filled out *white* registration card, together with their pocket cards, at one of the windows marked "Registration by Pocket Card." There the clerk will compare the two cards, stamp the pocket card and return it, and supply the Fellow with a badge, a copy of the official program and other printed matter of interest to those attending the annual session

THE MUNICIPAL AUDITORIUM IS ON THE RIGHT

who have not received cards for 1939 should secure them at once by writing to the American Medical Association, 535 North Dearborn Street, Chicago.

Members in Good Standing Eligible to Apply for Fellowship in the Association

Members in good standing in component county medical societies are members of constituent state associations and of the American Medical Association. All members in good standing may apply for Fellowship in the Scientific Assembly and are urged to qualify as Fellows before leaving home in order that pocket cards may be secured and brought to St. Louis so that registration can be more easily and more promptly effected.

Application forms may be had on request.

Those subscribers to THE JOURNAL who have not received pocket cards for 1939 should write to the American Medical Association in order to obtain application blanks and information as to further requirements.

Register Early

Fellows living in St. Louis, as well as all other Fellows who are in St. Louis on Monday and Tuesday, should register as early as possible. The names of those who register will be included in the issue of the *Daily Bulletin* appearing the next day, and this will enable visiting physicians to find friends if they have registered.

As previously stated, it will assist in registering if those who desire to qualify as Fellows will file their applications and qualify as Fellows by writing directly to the American Medical Association, 535 North Dearborn Street, Chicago, so that their Fellowship may be entered not later than April 24. Any applications that are received later than April 24 will be given prompt attention, but the Fellowship pocket card may not reach the applicant in time for him to register at the St Louis session.

It will be possible for members of the organization to qualify as Fellows at St. Louis. In order to do this, applicants for Fellowship will be required to fill out both sections of the front of the *blue* registration card and to sign the formal application that is printed on the reverse side of the card. It is suggested that those members who apply for Fellowship at St. Louis bring with them their state membership cards for 1939. The state membership card should be presented along with the filled in *blue* registration card at the window in the booth marked "Applicants for Fellowship and Invited Guests."

As already stated, registration can be effected more easily and more promptly if members will qualify as Fellows before leaving home.

Registration for General Officers and Delegates at the Hotel Statler

General Officers of the American Medical Association and members of the House of Delegates may register for the Scientific Assembly in Section III of the Assembly Room, adjacent to the Ball Room of the Hotel Statler. This arrangement is

made for the convenience of the members of the House of Delegates, which will convene on Monday morning at 10 o'clock in the Ball Room of the Hotel Statler. Delegates are requested to register for the Scientific Assembly before presenting credentials to the Reference Committee on Credentials of the House of Delegates. Registration of delegates for the Scientific Assembly will begin at 8 o'clock, Monday morning, May 15, and delegates are urged to register early so that all members of the House of Delegates may be seated in time for the opening session of the House.

ST. LOUIS HOTELS

A list of St. Louis hotels is presented for the benefit of those who expect to attend the annual session of the American Medical Association, May 15-19. Dr. Neil S. Moore is chairman of the Subcommittee on Hotels of the Local Committee on Arrangements and may be addressed at 910 Syndicate Trust Building, St. Louis, Mo. The advertising announcement and coupon for reservations appear on advertising page 107 of this issue. It is quite probable that no further reservations can be accepted by some of the hotels named in the list, but the chairman of the subcommittee on hotels will use his utmost endeavor to secure satisfactory accommodations for all who may apply. Since all reservations are cleared through the subcommittee on hotels, it will greatly expedite matters if requests for reservations are addressed directly to Dr. Moore, who, as stated, may be reached at 910 Syndicate Trust Building, St. Louis, Mo.

GENERAL SCIENTIFIC MEETINGS

MONDAY, MAY 15—2 P. M.

OPERA HOUSE, MUNICIPAL AUDITORIUM

PROGRAM BY ST. LOUIS PHYSICIANS

Emergency Treatment of Heart Failure.
ALPHONSE MCMAHON.

A Comparison of the St. Louis Type of Encephalitis with Other Neurotropic Virus Diseases. G. O. BROUN.

Operative Procedures on the Sympathetic Nervous System.
WILLIAM T. COUGHLIN.

Primary Carcinoma of the Lung.
M. F. ARBUCKLE and EVARTS A. GRAHAM.

Use of the Polysaccharide Skin Test in the Serum Treatment of Lobar Pneumonia.
L. D. THOMPSON, JOSEPH EDWARDS and C. L. HOAGLAND.

Electrical Transcriptions of Speech Following Closure and Elongation of Cleft Palates. JAMES BARRETT BROWN.

Roentgen Aids in Chest Diagnosis. L. R. SANTE.

TUESDAY, MAY 16

MEDICAL DIVISION: GOLD ROOM OF THE HOTEL JEFFERSON

9 A. M.

Allergy and Dermatology.
MARION B. SULZBERGER, New York.

The Treatment of Insomnia. LOUIS J. KARNOSH, Cleveland.

Focal Infections and Systemic Disease: A Critical Appraisal. HOBART A. REIMANN and W. PAUL HAVENS, Philadelphia.

The Autonomic Nervous System and Experimental Cardiovascular Disease. G. E. HALL, Toronto, Canada.

Diagnosis and Treatment of Pellagra, Beriberi and Flavin Deficiency (Lantern Demonstration).
TOM D. SPIES, Cincinnati.

Obliterative Arterial Disease of the Lower Extremities: Diagnosis and Principles of Treatment (Lantern Demonstration). LELAND S. MCKITTRICK, Boston.

2 P. M.

PANEL DISCUSSION ON PNEUMONIA

Each speaker is limited to fifteen minutes. Following the presentation of papers there will be a discussion based on questions submitted from the audience. Each question will be referred to one of the speakers for answer.

ERNEST E. IRONS, Moderator, Chicago

Pneumonia as a Public Health Problem: Geographic Distribution of Types; State Programs.
ADOLPH S. RUMREICH, Washington, D. C.

Etiology, Experimental and General; Pathology (Infection; Mechanism of Invasion; Bacteremia, Variations, Types, Significance in Relation to Therapy).
O. H. ROBERTSON, Chicago.

Serum Therapy: Types; Type Serums; Standardization; Clinical Results. JESSE G. M. BULLOWA, New York.

Chemotherapy (Brief Historical Outline); Ethylhydrocupreine; Sulfanilamide; Sulfapyridine; Comparison with Serum Therapy. COLIN M. MACLEOD, New York.

Oxygen Therapy: Indications and Methods of Application; Relation to Other Therapy.
M. A. BLANKENHORN, Cincinnati.

General Therapy; Use of Specific Therapies Combined with Individualized Care of Patient; Heart Complications; Pneumonia as a Major Emergency.
ROGER I. LEE, Boston.

TUESDAY, MAY 16

SURGICAL DIVISION: OPERA HOUSE OF MUNICIPAL AUDITORIUM

9 A. M.

Surgical Treatment of Peptic Ulcer (Lantern and Motion Picture Demonstration).
WILLIAM F. RIENHOFF JR., Baltimore.

Progress in the Treatment of Patients with Severe Burns (Motion Picture Demonstration).
ROY D. MCCLURE, Detroit.

The Treatment of Peritonitis (Lantern Demonstration).
THOMAS G. ORR, Kansas City, Mo.

Diseases of the Heart and Pericardium in Which Surgical Therapy May Be Indicated (Lantern and Motion Picture Demonstration). ALFRED BLALOCK, Nashville, Tenn.

Surgical Aspects of Carcinoma of the Stomach.
ALFRED J. BROWN, Omaha.

The Automobile and the Fractured Spine (Lantern Demonstration). H. EARLE CONWELL, Birmingham, Ala.

2 P. M.

PANEL DISCUSSION ON BILIARY TRACT DISEASE

Each speaker is limited to twenty minutes. Following the presentation of papers there will be a discussion based on questions submitted from the audience. Each question will be referred to one of the speakers for answer.

FRANK H. LAHEY, Moderator, Boston

Physiology of the Biliary Tract. ANDREW C. IVY, Chicago.

Differential Diagnosis of Jaundice.
I. S. RAVDIN, Philadelphia.

The Bleeding Tendency in Jaundice.
JOHN G. MATEER, Detroit.

Acute Cholecystitis. H. W. CAVE, New York.

Strictures and Injuries to Bile Ducts.
WALTMAN WALTERS, Rochester, Minn.

Common and Hepatic Duct Stones.
FRANK H. LAHEY, Boston.

SYMPOSIUM ON HEALTH PROBLEMS IN EDUCATION

A third Symposium on Health Problems in Education, under the sponsorship of the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, together with the Section on Pediatrics, the Section on Preventive and Industrial Medicine and Public Health, the Section on Ophthalmology and the Section on Laryngology, Otology and Rhinology of the American Medical Association, will be held in Assembly Room 1, Municipal Auditorium, St. Louis, May 16, at 2 p. m. Dr. S. Judd Beach, Portland, Maine, will preside. The following program will be presented:

Symposium on School Health Policies

School Health Problems:

From the Point of View of a School Physician.
J. H. HUMPHREY, St. Louis.

From the Point of View of a School Administrator.

The headquarters of the Art Association in St. Louis will be in booth 15A of the Municipal Auditorium. Art pieces will be accepted for this art show in the following classifications: (1) oils, both (*a*) portrait and (*b*) landscape; (2) water colors; (3) sculpture; (4) photographic art; (5) etchings; (6) ceramics; (7) pastels; (8) charcoal drawings; (9) book binding; (10) wood carving; (11) metal work (jewelry) There will be more than sixty valuable prize awards.

The William Beaumont Exhibit and the Exhibit of Medals

Many visitors to St. Louis during the annual session of the American Medical Association will be interested in the collection of letters and notebooks relating to Dr. William Beaumont, the pioneer American physiologist, who served in St. Louis as an army surgeon and later became a busy practitioner of medicine in St. Louis. Dr. Beaumont was one of the early presidents of the St. Louis Medical Society. The most important scientific collection of Beaumontiana in existence can be seen at the Library of Washington University School of Medicine, Euclid Avenue and Kingshighway.

At the Library of the St. Louis Medical Society will be a display of medals, plaquettes and coins in the Hugo W. Bartscher Room on the library floor. This exhibit consists of tokens of honors conferred on physicians and commemorative disks of epoch making contributions to medicine. Some of these are curious "touch pieces," coins that were given to victims of the King's Evil (scrofula or struma) when the rulers of Great Britain "touched" such patients to cure them by the "divine power of royalty." Plastic disks and plates are actually miniature monuments to achievements in medical science. They are not ordinarily exhibited to the public It is gratifying that the owners have lent their possessions to this unique cooperative display.

WOMEN'S ACTIVITIES

Program of Entertainment by Woman's Auxiliary

Entertainment for all women attending the St. Louis session of the American Medical Association and of the national Woman's Auxiliary, May 15-19, has been arranged by the Committee on Women's Activities.

St. Louis women and preconvention guests are requested to register in advance at Women's Headquarters at Hotel Chase in St. Louis Saturday May 13 between 1 and 4 p. m. or on Sunday May 14 between 10 a. m. and 4 p. m. Registration will continue from 8:30 a. m. to 4 p. m., Monday, Tuesday, Wednesday and Thursday, May 15, 16, 17 and 18, and from 8:30 a. m. to 11 a. m., Friday, May 19. All visiting women are requested to register as soon as possible after arrival.

SATURDAY, MAY 13

4:00 p. m. — Finance Committee Meeting.

SUNDAY, MAY 14

10:00 a. m. to 4:00 p. m. — Registration. Hostess Committee to receive visitors in afternoon.

4:00 p. m. to 7:00 p. m. — Tea for the National Board of Directors and all visiting ladies in honor of Mrs. Charles C. Tomlinson, National President, as guests of Mrs. Willard Bartlett, 53 Westmoreland Place, the Board of St. Louis Auxiliary, the Convention Vice Chairman, the Chairman and Cochairmen of subcommittees assisting.

MONDAY, MAY 15

9:30 a. m. — National board meeting, Regency Room, Hotel Chase.

1:30 p. m. to 4:45 p. m. — Visits to St. Louis County private gardens and teas. Visits will be made to the private gardens of Mr. and Mrs. Horton Watkins, Mrs. Joseph W. Lewis, Dr. and Mrs. Borden S. Veeder, Mr. and Mrs. Oliver K. Bovard, Dr. and Mrs. Vilray P. Blair, Mr. and Mrs. Frank Mesker, Mr. Joseph Desloge and Mr. and Mrs. Samuel W. Fordyce. Bus fare 75 cents. FIFTY TROPHIES AND PRIZES

Thirty-six holes of golf will be played in competition for the fifty trophies and prizes in the nine events. Trophies will be awarded for the Association Championship, thirty-six holes

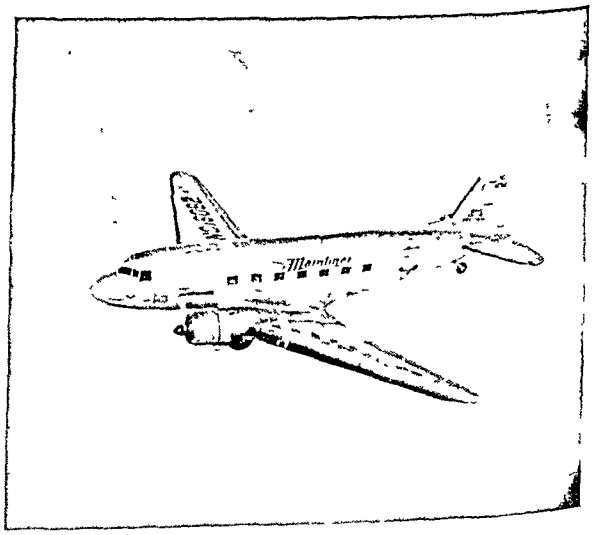
NORWOOD HILLS COUNTRY CLUB, WHERE A. M. G. A. GOLF TOURNAMENT WILL BE HELD MAY 15

gross, the Will Walter Trophy; the Association Handicap Championship, thirty-six holes net, the Detroit Trophy; the Championship Flight, First Gross, thirty-six holes, the St. Louis Trophy; the Championship Flight, First Net, thirty-six holes, the President's Trophy; the Eighteen Hole Championship, the Golden State Trophy; the Eighteen Hole Handicap Championship, the Ben Thomas Trophy; the Maturity Event, limited to Fellows over 60 years of age, the Minneapolis Trophy; the Oldguard Championship, limited to competition of past presidents, the Wendell Phillips Trophy, and the Kickers Handicap, the Atlantic City Trophy. Forty other prizes will be awarded for the various classes.

FELLOWS IN EVERY STATE OF THE UNION

E. S. Edgerton of 106 West Main Street, Wichita, Kan., is president. George Washington Hall of Chicago and James W. Morgan of San Francisco are vice presidents of the A. M. G. A., which was organized in 1915 by Will Walter, Wendell Phillips and Gene Lewis and now totals 1,464 members representing every state in the Union. The living past presidents include Thomas Hubbard of Ashtabula, Ohio, Fred Bailey of St. Louis, Robert Moss of LaGrange, Texas, Charlton Wallace of New York, Will Walter of Evanston, Ill., James Eaves of Oakland, Calif., D Chester Brown of Danbury, Conn., W. D. Sheldon of Rochester, Minn., Walter Schaller of San Francisco, Edwin Zabriskie of New York, Frank A. Kelly of Detroit, John Welsh Croskey of Philadelphia, Homer K. Nicoll of Chicago, Charles Lukens of Toledo, M. M. Cullom of Nashville, W. Albert Cook of Tulsa, Okla., and Walt P. Conaway of Atlantic City.

GRAYSON CARROLL HEADS ST. LOUIS GOLF COMMITTEE



The St Louis committee is under the chairmanship of Grayson Carroll, 539 North Grand Boulevard. St Louis. He will be assisted by Jack Eimer as secretary, Fred Bailey and Ross Woolsey.

TWO EIGHTEEN HOLE COURSES

The twenty-fifth tournament of the American Medical Golfing Association at the Norwood Hills Country Club promises to be a wonderful affair. The club is one of the most elaborate in the country, with two beautiful courses. The A. M. G. A. officers anticipate that some 250 to 300 medical golfers from all parts of the United States will play thirty-six holes in St. Louis on May 15.

APPLICATION FOR MEMBERSHIP

All male Fellows of the American Medical Association are eligible and are cordially invited to become members of the

FLYING TO ST. LOUIS

A. M. G. A. Write Executive Secretary Bill Burns, 2020 Olds Tower, Lansing, Mich., for an application blank. Participants in the tournament are required to furnish their home club handicap, signed by the club secretary. No handicap over 30 is allowed, except in the Kickers (blind bogey). Only active Fellows of the A. M. G. A. may compete for prizes. No trophy is awarded a Fellow who is absent from the annual dinner.

THE PROGRAMS OF THE SECTIONS

Outline of the Scientific Proceedings—The Preliminary Program and the Official Program

The following papers are announced to be read before the various sections. The order here is not necessarily the order that will be followed in the Official Program, nor is the list complete. The Official Program will be similar to the programs issued in previous years and will contain the final program of each section with abstracts of the papers, as well as lists of committees, program of the Opening General Meeting, list of entertainments, map of St. Louis, and other information. To prevent misunderstandings and protect the interest of advertisers, it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each Fellow on registration.

SECTION ON PRACTICE OF MEDICINE

MEETS IN GOLD ROOM OF HOTEL JEFFERSON

OFFICERS OF SECTION

Chairman—N. C. GILBERT, Chicago.
Vice Chairman—L. H. BRIGGS, San Francisco.
Secretary—FRED M. SMITH, Iowa City.
Executive Committee—JOHN H. MUSSER, New Orleans; FRANCIS G. BLAKE, New Haven, Conn.; N. C. GILBERT, Chicago.

Wednesday, May 17—9 a. m.

The Treatment of Massive Hemorrhage Due to Peptic Ulcer (Lantern Demonstration).
JOHN S. LA DUE, Minneapolis.
Complications Following the Administration of Sulfanilamide (Lantern Demonstration).
CURTIS F. GARVIN, Cleveland.
The Frank Billings Lecture. GEORGE DOCK, Pasadena, Calif.
The Symptomatology of Lymphoma: Its Endless Variety.
JAMES H. MEANS, Boston.
The Reaction of Peripheral Blood and Bone Marrow in Chronic Hemorrhage and in Essential Thrombocytopenic Purpura (Lantern Demonstration).
LOUIS R. LIMARZI and EMIL SCHLEICHER, Chicago.
The Differential Diagnosis and Therapeutic Rationale in Thrombocytopenic Purpura (Lantern Demonstration).
CHARLES A. DOAN, B. K. WISEMAN and SLOAN J. WILSON, Columbus.

Thursday, May 18—9 a. m.

Election of Officers
Parathyroid Insufficiency with Symmetrical Cerebral Calcification: Report of Three Cases, in One of Which the Patient Was Treated with Dihydrotachysterol (Lantern Demonstration).
L. MCKENDREE EATON and SAMUEL F. HAINES, Rochester, Minn.
Chairman's Address. N. C. GILBERT, Chicago.
Coronary Artery Reflexes in Acute Occlusion (Experimental) (Lantern Demonstration).
G. E. HALL, Toronto, Canada.
The Mechanism of Death in Pulmonary Embolism (Lantern Demonstration).
GEZA DE TAKATS and GEORGE K. FENN, Chicago.
The Morgagni-Adams-Stokes Syndrome with Special Reference to Prognosis and Treatment (Including the Use of Digitalis and Epinephrine in Oil) (Lantern Demonstration).
F. L. CHAMBERLAIN and PAUL D. WHITE, Boston.
The Delayed Appearance of Heart Disease After Rheumatic Fever (Lantern Demonstration).
EDWARD F. BLAND, Boston.
Fifteen Years' Observation of Children with Rheumatic Heart Disease (Lantern Demonstration).
WILLIAM D. STROUD, Philadelphia.

Friday, May 19—9 a. m.

JOINT MEETING WITH SECTION ON PHARMACOLOGY AND THERAPEUTICS

Treatment of the Menopause (Lantern Demonstration).
ELMER L. SEVRINGHAUS, Madison, Wis.
An Evaluation of Therapy of Peptic Ulcer.
CLARENCE F. G. BROWN, Chicago, and R. E. DOLKART, Boston.
Treatment of Pneumonia (Lantern Demonstration).
M. HERBERT BARKER, Chicago.
Bromide Intoxication: Report of Fifteen Cases (Lantern Demonstration). LEWIS P. GUNDRY, Baltimore.
Clinical and Experimental Studies on Vitamin K (Lantern Demonstration). H. P. SMITH, Iowa City.
The Preoperative and Postoperative Use of Vitamin K in Cases of Obstructive Jaundice (Lantern Demonstration).
HUGH R. BUTT, ALBERT M. SNELL and ARNOLD E. OSTERBERG, Rochester, Minn.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

MEETS IN OPERA HOUSE OF MUNICIPAL AUDITORIUM

OFFICERS OF SECTION

Chairman—HENRY W. CAVE, New York.
Vice Chairman—FRED W. BAILEY, St. Louis.
Secretary—ARTHUR W. ALLEN, Boston.
Executive Committee—ROBERT S. DINSMORE, Cleveland; HUGH H. TROUT, Roanoke, Va.; HENRY W. CAVE, New York.

Wednesday, May 17—2 p. m.

Reactions of the Peritoneum to Trauma and Infection: Further Experimental Studies (Lantern Demonstration).
FREDERICK A. COLLER, HENRY K. RANSOM and CHARLES SHERRILL RIFE, Ann Arbor, Mich.
Stages in Peritonitis Based on the Defense Mechanism in Relation to Treatment (Lantern Demonstration).
BERNHARD STERNBERG, Toledo, Ohio.
Complications of Appendical Peritonitis (Lantern Demonstration). GEORGE D. LILLY, Miami, Fla.
One Hundred per Cent Oxygen: Indications for Its Use and Methods of Administration to Surgical Patients (Lantern and Motion Picture Demonstration).
WALTER M. BOOTHBY, CHARLES W. MAYO and W. RANDOLPH LOVELACE II, Rochester, Minn.
Surgical Lesions in the Paratrigeminal Area (Lantern Demonstration).
LOYAL DAVIS and JOHN MARTIN, Chicago.
Cerebral Complications Following Surgical Operation (Lantern Demonstration).
ALBERT BEHREND and HELENA E. RIGGS, Philadelphia.

Thursday, May 18—2 p. m.

Thrombophlebitis: The Etiologic Factor of Vasospasm and the Treatment by Sympathetic Block (Lantern Demonstration).
ALTON OCHSNER and MICHAEL E. DEBAKEY, New Orleans.

Arteriosclerotic Gangrene: Relation of the Amputation Stump to Morbidity and Mortality (Lantern Demonstration).
FREDERIC W. TAYLOR, Indianapolis.

Major Amputations in Advance Peripheral Arterial Obliterative Disease (Lantern Demonstration).
HENRY H. FAXON, Boston.

Chairman's Address: Chronic Intractable Ulcerative Colitis; a Surgical Problem (Lantern Demonstration).
HENRY W. CAVE, New York.

Control of the Hemorrhagic Tendency in Obstructive Jaundice by the Use of Vitamin K (Lantern Demonstration).
JOHN D. STEWART, Boston.

Congenital Lesions of the Neck (Lantern Demonstration).
CONRAD J. BAUMGARTNER, Los Angeles.

Ludwig's Angina, Retropharyngeal Abscess and Other Deep Abscesses of the Head and Neck (Lantern Demonstration).
MANUEL GRODINSKY, Omaha.

Friday, May 19—2 p. m.

Election of Officers

Surgical Aspects of Carcinoma of the Large Bowel (Lantern Demonstration).
HARVEY B. STONE and SAMUEL MCLANAHAN, Baltimore.

Hypoproteinemia in Surgical Patients (Lantern Demonstration).
I. S. RAVDIN, ALFRED STENGEL JR. and CECILIA RIEGEL, Philadelphia.

The Immediate and Late Results of Surgical Treatment of Acute Perforation of Peptic Ulcer (Lantern Demonstration).
HAROLD LINCOLN THOMPSON, Los Angeles.

Pathogenesis of Thyrotoxicosis with Crisis (Lantern Demonstration).
HAROLD L. FOSS, Danville, Pa.

Lateral Aberrant Thyroid Tumors (Lantern Demonstration).
GEORGE CRILE JR., Cleveland.

The Management of True Intrathoracic Goiter (Lantern Demonstration).
FRANK H. LAHEY, Boston.

SECTION ON OBSTETRICS AND GYNECOLOGY

MEETS IN OPERA HOUSE OF MUNICIPAL AUDITORIUM

OFFICERS OF SECTION

Chairman—HARVEY B. MATTHEWS, Brooklyn.

Vice Chairman—LUDWIG A. EMGE, San Francisco.

Secretary—NORMAN F. MILLER, Ann Arbor, Mich.

Executive Committee—M. PIERCE RUCKER, Richmond, Va.; E. D. PLASS, Iowa City; HARVEY B. MATTHEWS, Brooklyn.

Wednesday, May 17—9 a. m.

SYMPOSIUM ON LESIONS OF THE VULVA

Anatomy of the Lower Genital Tract (Lantern Demonstration).
ROLLO E. MCCOTTER, Ann Arbor, Mich.

Venereal and Nonvenereal Granulomas of the Vulva (Lantern Demonstration).
EMMERICH VON HAAM, Columbus.

Benign and Malignant Tumors of the Vulva (Lantern Demonstration).
CLAIR E. FOLSOME, Ann Arbor, Mich.

Atrophy of the Vulva (Lantern Demonstration).
FRED L. ADAIR and M. EDWARD DAVIS, Chicago.

Backache During Pregnancy and Its Management (Lantern Demonstration).
EDMUND LISSACK, Concordia, Mo.

The Role of Hypothyroidism in the Causation of Abortion, Especially of the "Missed" Variety (Lantern Demonstration).
E. L. KING, New Orleans.

Thursday, May 18—9 a. m.

The Responsibility of the Medical Profession in the Movement of Birth Control.
GEORGE W. KOSMAK, New York.

The Effects of Obstetric Analgesia on the Newborn Infant (Lantern Demonstration).

Studies in Neonatal Asphyxia (Lantern Demonstration).
DAVID C. KIMBALL, WYMAN C. C. COLE and L. E. DANIELS, Detroit.

Postoperative Care of the Urinary Bladder (Lantern Demonstration).
RICHARD W. TELINDE and J. DONALD WOODRUFF, Baltimore.

Chairman's Address: Obstetric Shock; Its Causes, Recognition and Management (Lantern Demonstration).
HARVEY B. MATTHEWS, Brooklyn.

Friday, May 19—9 a. m.

Election of Officers

The Diagnosis and Treatment of Hyperthyroidism Associated with Pregnancy.
BERNARD PORTIS and HAROLD A. ROTH, Chicago.

Diagnosis and Treatment of Varicosities of the Broad Ligament (Lantern Demonstration).
W. O. JOHNSON, Louisville, Ky.

Stress Urinary Incontinence and Its Relation to Cystocele (Lantern Demonstration). JOSHUA W. DAVIES, New York.

A Study of Cervical Polyps (Lantern Demonstration).
S. LEON ISRAEL, Philadelphia.

The Treatment of Retrodisplacements of the Uterus (Lantern Demonstration). WALTER T. DANNREUTHER, New York.

SECTION ON OPHTHALMOLOGY

MEETS IN ASSEMBLY ROOM 1 OF MUNICIPAL AUDITORIUM

OFFICERS OF SECTION

Chairman—S. JUDD BEACH, Portland, Maine.

Vice Chairman—FREDERICK C. CORDEZ, San Francisco.

Secretary—DERRICK VAIL, Cincinnati.

Executive Committee—WILLIAM L. BENEDICT, Rochester, Minn; PARKER HEATH, Detroit; S. JUDD BEACH, Portland, Maine.

Wednesday, May 17—2 p. m.

Chairman's Address (Lantern Demonstration).
S. JUDD BEACH, Portland, Maine.

Thoughts on Office Practice. ALLEN GREENWOOD, Boston.

A Simple Method of Plotting, Recording and Interpreting Disturbances of Ocular Motility (Lantern Demonstration).
WALTER B. LANCASTER, Boston.

The Treatment of Secondary Glaucoma (Lantern Demonstration). SANFORD R. GIFFORD, Chicago.
Discussion to be opened by EDWARD C. ELLETT, Memphis, Tenn.

Iridencleisis in Glaucoma (Lantern Demonstration).
EVERETT L. GOAR and JACOB F. SCHULTZ, Houston, Texas.
Discussion to be opened by CLYDE A. CLAPP, Baltimore.

The Value of Early Operation in Chronic Primary Glaucoma (Lantern Demonstration).
ALGERNON B. REESE, New York.
Discussion to be opened by HARRY S. GRADLE, Chicago.

Cyclodialysis with Metal Implant in the Treatment of Glaucoma (Lantern and Motion Picture Demonstration).
MANUEL U. TRONCOSO, New York.
Discussion to be opened by OTIS R. WOLFE, Marshalltown, Iowa.

Thursday, May 18—2 p. m.

Ocular Leprosy in the United States (Lantern Demonstration).
JOHN J. PRENDERGAST, St. Paul.
Discussion to be opened by GIDEON M. VAN POOLE and FORREST J. PINKERTON, Honolulu, Hawaii.

Primary Tumors of the Optic Nerve: A Phenomenon of von Recklinghausen's Disease; a Clinical and Pathologic Study with a Report of Five Cases and a Review of the Literature (Lantern Demonstration).
FREDERICK A. DAVIS, Madison, Wis
Discussion to be opened by PERCIVAL BAILEY, Chicago, and JESSE M. LEVITT, Brooklyn.

Malignant Melanoma of Uvea—So-Called Sarcoma: Problems in Diagnosis (Lantern Demonstration).
THEODORE L. TERRY, Boston.
Discussion to be opened by EVERETT C. MOULTON, Fort Smith, Ark., and ALLEN GREENWOOD, Boston.

Experimental Studies on Ocular Tuberculosis: IV. Studies in the Immune-Allergic Rabbit (Lantern Demonstration).
ALAN C. WOODS and EARL L. BURKY, Baltimore.
Discussion to be opened by MARTIN HAYWARD POST, St. Louis, and ALBERT L. BROWN, Cincinnati.

A Study of Exfoliation of the Lens Capsule, "Glaucoma Capsularis," with a Report of Forty Cases (Lantern Demonstration).
S. RODMAN IRVINE, Los Angeles.
Discussion to be opened by DANIEL B. KIRBY, New York, and PARKER HEATH, Detroit.

Cataract Following Inhalation of Paradichlorobenzene (Lantern Demonstration). MILTON L. BERLINER, New York.
Discussion to be opened by JAMES E. LEBENSOHN, Chicago.

Friday, May 19—2 p. m.

Executive Session

Election of Officers

Observations on the Eye and Their Significance in Traffic Court Cases (Lantern Demonstration).
LOWELL S. SELLING, Detroit.
Discussion to be opened by ARTHUR J. BEDELL, Albany, N. Y., and ALBERT C. SNELL, Rochester, N. Y.

Ophthalmology's Place in the Prevention of Blindness.
F. PARK LEWIS, Buffalo.
Discussion to be opened by EDWARD V. L. BROWN, Chicago, and CONRAD BERENS, New York.

Progressive Myopia, Keratoconus and Keratoglobus: Their Etiology and Treatment. JULIAN Y. MALONE, Milwaukee.
Discussion to be opened by WILLIAM L. BENEDICT, Rochester, Minn., and MEYER WIENER, St. Louis.

Interstitial Keratitis Caused by Specific Sensitivity (Lantern Demonstration).
ABBOTT M. DEAN, F. W. DEAN and GUY R. MCCUTCHAN, Council Bluffs, Iowa.
Discussion to be opened by ALBERT D. RUEDEMANN, Cleveland, and ALBERT N. LEMOINE, Kansas City, Mo.

SECTION ON LARYNGOLOGY, OTOLOGY AND RHINOLOGY

MEETS IN ASSEMBLY ROOM 1 OF MUNICIPAL AUDITORIUM

OFFICERS OF SECTION

Chairman—H. MARSHALL TAYLOR, Jacksonville, Fla.
Vice Chairman—HAROLD A. FLETCHER, San Francisco.
Secretary—LEROY A. SCHALL, Boston.

Nonsurgical Aspects of the Kidney Stone Problem (Lantern Demonstration).
FULLER ALBRIGHT, RICHARD CHUTE and HIRSH W. SULKOWITCH, Boston.
Discussion to be opened by CHARLES C. HIGGINS, Cleveland, and WILLIAM F. BRAASCH, Rochester, Minn.
The Action of Drugs on the Caliber of the Coronary Vessels (Lantern Demonstration). LOUIS N. KATZ, Chicago.
Discussion to be opened by FRED M. SMITH, Iowa City.
The Effects of Pituitary Extracts on Metabolism (Lantern Demonstration).
J. B. COLLIP, A. H. NEUFELD and O. F. DENSTEDT, Montreal, Canada.
Discussion to be opened by ELMER L. SEVRINGHAUS, Madison, Wis., and DAVID P. BARR, St. Louis.
The Present Status of Lipocaic (Lantern Demonstration).
LESTER R. DRAGSTEDT, Chicago.
Discussion to be opened by DAVID H. ROSENBERG, Chicago.

Friday, May 19—9 a. m.

JOINT MEETING WITH SECTION ON PRACTICE OF MEDICINE, GOLD ROOM OF HOTEL JEFFERSON

Treatment of the Menopause (Lantern Demonstration).
ELMER L. SEVRINGHAUS, Madison, Wis.
An Evaluation of Therapy of Peptic Ulcer.
CLARENCE F. G. BROWN, Chicago, and R. E. DOLKART, Boston.
Treatment of Pneumonia (Lantern Demonstration).
M. HERBERT BARKER, Chicago.
Bromide Intoxication: Report of Fifteen Cases (Lantern Demonstration). LEWIS P. GUNDRY, Baltimore.
Clinical and Experimental Studies on Vitamin K (Lantern Demonstration). H. P. SMITH, Iowa City.
The Preoperative and Postoperative Use of Vitamin K in Cases of Obstructive Jaundice (Lantern Demonstration).
HUGH R. BUTT, ALBERT M. SNELL and ARNOLD E. OSTERBERG, Rochester, Minn.

SECTION ON PATHOLOGY AND PHYSIOLOGY

MEETS IN ASSEMBLY ROOM 2 OF MUNICIPAL AUDITORIUM

OFFICERS OF SECTION

Chairman—M. B. VISSCHER, Minneapolis.
Vice Chairman—F. W. HARTMAN, Detroit.
Secretary—J. J. MOORE, Chicago.
Executive Committee—W. E. GARREY, Nashville, Tenn.; ROY R. KRACKE, Emory University, Ga.; M. B. VISSCHER, Minneapolis.

Wednesday, May 17—9 a. m.

Chairman's Address: The Restriction of the Coronary Flow as a Factor in Heart Failure (Lantern Demonstration).
M. B. VISSCHER, Minneapolis.
Experimental Studies on the Pathogenesis of Nephritis (Lantern Demonstration). J. P. SIMONDS, Chicago.
A Method for Producing Persistent Hypertension by Cellophane (Lantern Demonstration). IRVINE H. PAGE, Indianapolis.
Biologic Effects of Testosterone Propionate on the Human Female (Lantern Demonstration).
SAMUEL H. GEIST, UDALL J. SALMON and JOSEPH A. GAINES, New York.
Temperature Factor in Cancer and Embryonal Cell Growth (Lantern Demonstration).
LAWRENCE W. SMITH and TEMPLE S. FAY, Philadelphia.
The Correlation of the Pathologic Lesions and the Anoxia Resulting from Alcohol (Lantern Demonstration).
F. W. HARTMAN, Detroit.

Relations Between Specific Immunity, Allergy and Anaphylaxis in Tuberculosis (Lantern Demonstration).
H. J. CORPER, MAURICE L. COHN and A. P. DAMEROW, Denver.

Thursday, May 18—9 a. m.

Election of Officers

SYMPOSIUM ON SULFANILAMIDE

Experimental Chemotherapy with Sulfanilamide and Related Compounds. SANFORD M. ROSENTHAL, Washington, D. C.

Action of Sulfanilamide Analyzed by Tissue Culture Methods (Lantern Demonstration). JOSEPH T. KING, Minneapolis.

Anticatalase Property of Sulfanilamide in Relation to the Drug's Bacteriostatic Action (Lantern Demonstration).
RALPH R. MELLON, Pittsburgh.

The Influence of Proteolytic Products on the Effectiveness of Sulfanilamide (Lantern Demonstration).
JOHN S. LOCKWOOD, Philadelphia.

Effect of Sulfapyridine Alone and with Serum and in Serum of Treated Pneumonia Patients on Pneumococcus Infected Marrow Cultures (Lantern Demonstration).
JESSE G. M. BULLOWA, New York; EDWIN E. OSGOOD, Portland, Ore., and SAMUEL C. BUKANTZ, New York.

Friday, May 19—9 a. m.

JOINT MEETING WITH SECTION ON NERVOUS AND MENTAL DISEASES

The Neurotropic Viruses (Lantern Demonstration).
L. S. KING, Princeton, N. J.
Discussion to be opened by ROBERT G. GREEN, Minneapolis, and RICHARD B. RICHTER, Chicago.

SYMPOSIUM ON VITAMIN DEFICIENCIES AND RELATED NEURAL DISORDERS

Vitamin Deficiencies and the Nervous System: A Consideration of the Contribution of Animal Experimentation.
GEORGE R. COWGILL, New Haven, Conn.

The Physiologic Action of the Vitamin B Complex.
F. H. LEWY, Philadelphia.

The Neuropathology of Vitamin B Deficiency.
HARRY M. ZIMMERMAN, New Haven, Conn.

Clinical Aspects of Vitamin B Deficiencies (Lantern Demonstration).
CHARLES D. ARING, TOM D. SPIES and J. P. EVANS, Cincinnati.
Discussion to be opened by ARTHUR WEIL, Chicago, and HANS H. REESE, Madison, Wis.

SECTION ON NERVOUS AND MENTAL DISEASES

MEETS IN ASSEMBLY ROOM 4 OF MUNICIPAL AUDITORIUM

OFFICERS OF SECTION

Chairman—FRANCIS C. GRANT, Philadelphia.

Vice Chairman—RICHARD M. BRICKNER, New York.

Secretary—PAUL C. BUCY, Chicago.

Executive Committee—HENRY R. VIETS, Boston; SAMUEL D. INGHAM, Los Angeles; FRANCIS C. GRANT, Philadelphia.

Wednesday, May 17—2 p. m.

The Use of Guanidine Compounds in the Treatment of Myasthenia Gravis (Lantern Demonstration).
ANN S. MINOT, KATHARINE DODD and S. S. RIVEN, Nashville, Tenn.

Myasthenia Gravis (Lantern Demonstration).
HENRY R. VIETS and ROBERT S. SCHWAB, Boston.
Discussion to be opened by FOSTER KENNEDY, New York, and J. C. McKINLEY, Minneapolis.

Chairman's Address: The Surgical Treatment of Pituitary Adenomas (Lantern Demonstration).
FRANCIS C. GRANT, Philadelphia.

Irradiation in the Treatment of Pituitary Adenomas (Lantern Demonstration). M. C. SOSMAN, Boston.
Discussion to be opened by GEORGE W. CHAMBERLIN, Philadelphia, and ERNEST SACHS, St. Louis.

The Role of Potassium Chloride in the Treatment of Ménière's Syndrome (Lantern Demonstration).
MADELAINE R. BROWN, Boston.

Ménière's Disease: Medical and Surgical Treatment (Lantern Demonstration).
A. W. ADSON and M. N. WALSH, Rochester, Minn.
Discussion to be opened by F. D. LATHROP, Ann Arbor, Mich., and CLAUDE C. COLEMAN, Richmond, Va.

Thursday, May 18—2 p. m.

Election of Officers

The Posttraumatic Psychoneurotic State and Traumatic Encephalopathy (Lantern Demonstration).
WALTER F. SCHALLER, San Francisco.
Discussion to be opened by GEORGE W. HALL, Chicago, and SIDNEY I. SCHWAB, St. Louis.

The Differential Diagnosis of Anxiety Neurosis (Lantern Demonstration).
STANLEY COBB and M. E. COHEN, Boston.
Discussion to be opened by DAVID SLIGHT, Chicago, and LESLIE B. HOHMAN, Baltimore.

Results of Treatment in a Psychiatric Outpatient Department (Lantern Demonstration).
H. T. CARMICHAEL and J. H. MASSERMANN, Chicago.
Discussion to be opened by LLOYD H. ZIEGLER, Wauwatosa, Wis., and KARL A. MENNINGER, Topeka, Kan.

Probable Topography of the Sleep-Regulating Center (Lantern Demonstration). JOSEPH H. GLOBUS, New York.
Discussion to be opened by PERCIVAL BAILEY, Chicago, and JOHN F. FULTON, New Haven, Conn.

Delayed Paralysis of Nerves from Indirect Trauma.
J. M. NIELSEN, Los Angeles.
Discussion to be opened by L. J. POLLOCK, Chicago, and R. B. RANEY, Los Angeles.

Friday, May 19—9 a. m.

JOINT MEETING WITH SECTION ON PATHOLOGY AND PHYSIOLOGY, ASSEMBLY ROOM 2 OF MUNICIPAL AUDITORIUM

The Neurotropic Viruses (Lantern Demonstration).
L. S. KING, Princeton, N. J.
Discussion to be opened by ROBERT G. GREEN, Minneapolis, and RICHARD B. RICHTER, Chicago.

SYMPOSIUM ON VITAMIN DEFICIENCIES AND RELATED NEURAL DISORDERS

Vitamin Deficiencies and the Nervous System: A Consideration of the Contribution of Animal Experimentation.
GEORGE R. COWGILL, New Haven, Conn.

The Physiologic Action of the Vitamin B Complex.
F. H. LEWY, Philadelphia.

The Neuropathology of Vitamin B Deficiency.
HARRY M. ZIMMERMAN, New Haven, Conn.

Clinical Aspects of Vitamin B Deficiencies (Lantern Demonstration).
CHARLES D. ARING, TOM D. SPIES and J. P. EVANS, Cincinnati.
Discussion to be opened by ARTHUR WEIL, Chicago, and HANS H. REESE, Madison, Wis.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

MEETS IN ASSEMBLY ROOM 3 OF MUNICIPAL AUDITORIUM

OFFICERS OF SECTION

Chairman—BEDFORD SHELMIRE, Dallas, Texas.

Vice Chairman—ROBERT C. JAMIESON, Detroit.

Secretary—C. F. LEHMANN, San Antonio, Texas.

Executive Committee—PAUL A. O'LEARY, Rochester, Minn.; JOSEPH V. KLAUDER, Philadelphia; BEDFORD SHELMIRE, Dallas, Texas.

Wednesday, May 17—2 p. m.

Chairman's Address: Weeds Causing Contact Eczema (Lantern Demonstration).
BEDFORD SHELMIRE, Dallas, Texas.

Contact Dermatitis from Opium Derivatives: Special Reference to Occupational Aspects (Lantern Demonstration).
JAMES W. JORDON and EARL D. OSBORNE, Buffalo.
Discussion to be opened by M. B. SULZBERGER, New York.

Acne in a Group of University Students (Lantern Demonstration). FRANCIS W. LYNCH, St. Paul.
Discussion to be opened by JOSEPH GARDNER HOPKINS, New York.

Vitamin Therapy in Dermatology, with Particular Reference to Vitamin D Effects in Acne and Disease of Altered Calcium Usage (Lantern Demonstration).
MERLIN T.-R. MAYNARD, San Jose, Calif.
Discussion to be opened by PAUL GROSS, New York.

Roentgen Dosages in Dermatology.
GEORGE M. MACKEE and ANTHONY C. CIPOLLARO, New York.
Discussion to be opened by HARRY R. FOERSTER, Milwaukee.

Gentian Violet Treatment of Ringworm of the Scalp.
W. F. SPILLER and W. B. SHARP, Galveston, Texas.
Discussion to be opened by LESLIE M. SMITH, El Paso, Texas.

Hypertherm Treatments in Dermatology.
ELMORE B. TAUBER and LEON GOLDMAN, Cincinnati.
Discussion to be opened by PAUL A. O'LEARY, Rochester, Minn., and JULIEN E. BENJAMIN, Cincinnati.

Dermatofibrosarcoma Protuberans, with a Report of Six Cases (Lantern Demonstration).
GEORGE W. BINKLEY, Cleveland.
Discussion to be opened by JOHN H. LAMB, Oklahoma City.

Thursday, May 18—2 p. m.

Corneal Examination and Slit Lamp Microscopy in Diagnosis of Late Congenital Syphilis, Especially in Adults (Lantern Demonstration).
JOSEPH V. KLAUDER and ALFRED COWAN, Philadelphia.
Discussion to be opened by JAMES R. DRIVER, Cleveland.

A Study of Discrepancies in Serologic Reports: The "Positive Hinton-Negative Wassermann" Problem (Lantern Demonstration).
G. MARSHALL CRAWFORD and LEON F. RAY, Boston.
Discussion to be opened by UDO J. WILE, Ann Arbor, Mich.

The Value and Use of Mapharsen by the General Practitioner in Office Practice (Lantern Demonstration).
CHARLES R. REIN and FRED WISE, New York.
Discussion to be opened by GIRSCH D. ASTRACHAN, New York.

Granuloma Inguinale: Notes on Its Clinical Syndrome; Protozoan Nature of the Disease; Experimental Production (Lantern Demonstration).
ROBERT B. GREENBLATT, Augusta, Ga.
Discussion to be opened by HARRY M. ROBINSON, Baltimore.

The Action of Sodium Thiosulfate, Thiophenylsulfonic Acid and Formaldehyde Sulfoxylate in Arsenical and Mercurial Poisoning in Rabbits.
KATHLEEN B. MUIR, EVANGELINE STENHOUSE and S. WILLIAM BECKER, Chicago.
Discussion to be opened by CHARLES C. DENNIE, Kansas City, Mo.

Sugar Metabolism of the Skin (Lantern Demonstration).
THEODORE CORNBLEET, Chicago.
Discussion to be opened by HERMAN SHARLIT, New York.

Metabolic Studies in Patients with Pemphigus (Lantern Demonstration). JOHN H. TALBOTT, Boston.
Discussion to be opened by RICHARD S. WEISS, St. Louis, and C. GUY LANE, Boston.

Friday, May 19—2 p. m.

Election of Officers

Dermatitis of the Ears (Lantern Demonstration).
H. L. WILLIAMS JR., HAMILTON MONTGOMERY and WILLIAM N. POWELL, Rochester, Minn.
Discussion to be opened by JAMES HERBERT MITCHELL, Chicago.

Pruritus Ani et Vulvae (Lantern Demonstration).
WILLIAM HOWARD HAILEY and HUGH E. HAILEY, Atlanta, Ga.
Discussion to be opened by CARL W. LAYMON, Minneapolis.

The Senear-Usher Syndrome.
UDO J. WILE and HARRY L. ARNOLD JR., Ann Arbor, Mich.
Discussion to be opened by FRANCIS E. SENEAR, Chicago.

Generalized Herpes Zoster (Lantern Demonstration).
LESLIE P. BARKER, New York.
Discussion to be opened by NELSON PAUL ANDERSON, Los Angeles.

Poikiloderma (Lantern Demonstration).
ONIS G. HAZEL, Oklahoma City.
Discussion to be opened by FRED M. JACOB, Pittsburgh.

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

MEETS IN IVORY ROOM OF HOTEL JEFFERSON

OFFICERS OF SECTION

Chairman—I. C. RIGGIN, *Richmond, Va.*
Vice Chairman—H. S. DIEHL, *Minneapolis.*
Secretary—W. A. SAWYER, Rochester, N. Y.
Executive Committee—L. D. BRISTOL, New York; ROBERT T. LEGGE, Berkeley, Calif.; I. C. RIGGIN, Richmond, Va.

Wednesday, May 17—9 a. m.

Chairman's Address. I. C. RIGGIN, *Richmond, Va.*

Traumatic Heart Disease (Lantern Demonstration).
LOUIS F. BISHOP JR., New York.

Some Peculiarities in the Geography of Cancer (Lantern Demonstration).
JOSEPH W. MOUNTIN and HAROLD F. DORN, Washington, D. C.

The Hazards of Farming (Lantern Demonstration).
JOHN H. POWERS, Cooperstown, N. Y.

Depressed Skull Fractures (Lantern Demonstration).
MARK A. GLASER and FREDERICK P. SHAFER, Los Angeles.

Thursday, May 18—9 a. m.

A Study of the Pneumonias with Reference to Overcrowding and Cross Infection (Lantern Demonstration).
JULIEN E. BENJAMIN, Cincinnati.

Tuberculosis Among Hospital Personnel.
LEOPOLD BRAHDY, New York.

Tuberculosis Control. ROBERT E. PLUNKETT, *Albany, N. Y.*

The Intravenous Drip Method of Therapy Applied to Syphilis (Lantern Demonstration).
HAROLD T. HYMAN, LOUIS CHARGIN, JOHN L. RICE and WILLIAM LEIFER, New York.

The Relationship of Syphilis to Tuberculosis (Lantern Demonstration). SAMUEL GOLDBLATT, *Cincinnati*

Friday, May 19—9 a. m.

Election of Officers

Industrial Importance of Allergic Diseases to the Southern Pacific Railroad Company (Lantern Demonstration).
EDWARD MATZGER, San Francisco

Hard Facts About Psychiatry.
C. C. BURLINGAME, Hartford, Conn

Present Status of Benzene. P. A. DAVIS, Akron, Ohio

Dermatitis Among Plate Printers (Lantern Demonstration).
PAUL A. NEAL, Washington, D. C.

Pollinosis as a Problem in Preventive Medicine (Lantern Demonstration). R. V. ELLIS, Minneapolis.

SECTION ON UROLOGY

MEETS IN ASSEMBLY ROOM 3 OF MUNICIPAL AUDITORIUM

OFFICERS OF SECTION

Chairman—WILLIAM P. HERBST, Washington, D. C.
Vice Chairman—GRAYSON L. CARROLL, St. Louis.
Secretary—VINCENT J. O'CONOR, Chicago.
Executive Committee—HENRY W. E. WALTHER, New Orleans; ALBERT J. SCHOLL, Los Angeles; WILLIAM P. HERBST, Washington, D. C.

Wednesday, May 17—9 a. m.

SYMPOSIUM ON URINARY INJURIES

Diagnostic and Operative Factors in Traumatic Rupture of the Kidney (Lantern Demonstration).
FRANKLIN FARMAN, Los Angeles.

Rupture of Kidney (Lantern Demonstration).
GEORGE C. PRATHER, Boston.

Injuries of the Ureter (Lantern Demonstration).
CARL F. RUSCHE, Los Angeles

Intraperitoneal and Extraperitoneal Rupture of the Urinary Bladder (Lantern Demonstration).
E. J. MCCAGUE, Pittsburgh

Care of Traumatic Injuries of the Male Urethra (Lantern Demonstration). WILLIAM L. HORNADAY, Des Moines.

Traumatic "Epididymo-Orchitis."
GEORGE H. EWELL, Madison, Wis.

Thursday, May 18—9 a. m.

A New Method of Uretero-Intestinal Anastomosis with Utilization of Peritoneum (Lantern Demonstration).
ROY E. BRACKIN, Kenilworth, Ill.

Hypospadias (in the Male): The Operative Technic for the Correction of Penile Deformity and Reconstruction of the Urethra (Lantern Demonstration).
CHARLES M. MCKENNA, Chicago.

Chairman's Address: Renal Tuberculosis (Lantern Demonstration). WILLIAM P. HERBST, Washington, D. C.

Late Results Following Nephrectomy for Renal Neoplasm (Lantern Demonstration). J. T. PRIESTLEY, Rochester, Minn.

The Clinical Aspects of the Endocrine Function of the Testes in Man (Lantern Demonstration).
WILLIAM E. LOWER and E. P. MCCULLAGH, Cleveland.

The Endocrine Function of the Testes (Lantern Demonstration).
JAMES F. MCCAHEY, Philadelphia.

Friday, May 19—9 a. m.

Election of Officers

Genital Tuberculosis (Lantern Demonstration).
ELI A. MILLER, Denver, and M. J. LUSTOK, Spivak, Colo.

Factors in Recurrence of Renal Calculi (Lantern Demonstration). CHARLES C. HIGGINS, Cleveland.

Calcium and Phosphorus Excretion on Patients with Urinary Calculi. RUBIN FLOCKS, Iowa City.

Do Alkalis Used in the Treatment of Peptic Ulcer Cause Kidney Stones? (Lantern Demonstration.)
HERMAN L. KRETSCHMER and RALPH C. BROWN, Chicago.

The Treatment of Ureteral Calculus with Particular Reference to Transurethral Manipulation (Lantern Demonstration). GERSHOM J. THOMPSON, Rochester, Minn.

Ureteral Meatotomy: Its Significance and Description of a New Technic (Lantern Demonstration).
JOHN DUFF, New York.

SECTION ON ORTHOPEDIC SURGERY

MEETS IN ASSEMBLY ROOM 4 OF MUNICIPAL AUDITORIUM

OFFICERS OF SECTION

Chairman—OSCAR L. MILLER, Charlotte, N. C.

Vice Chairman—ROBERT V. FUNSTEN, Charlottesville, Va.

Secretary—GUY A. CALDWELL, New Orleans.

Executive Committee—FREMONT A. CHANDLER, Chicago; JOHN DUNLOP, Pasadena, Calif.; OSCAR L. MILLER, Charlotte, N. C.

Wednesday, May 17—9 a. m.

Excision of Patella in Cases of Hypertrophic Arthritis (Lantern Demonstration). E. J. BERKHEISER, Chicago.
Discussion to be opened by A. H. MEYER, Memphis, Tenn., and JACOB KULOWSKI, St. Joseph, Mo.

Sympathicoblastoma: A Report of Four Cases (Lantern Demonstration).
FREMONT A. CHANDLER and JOHN R. NORCROSS, Chicago.
Discussion to be opened by FRANK R. OBER, Boston, and G. K. CARPENTER, Nashville, Tenn.

Regeneration of the Growth Epiphyses of Long Bones (Lantern Demonstration).
EDWARD L. COMPERE, SAMUEL W. BANKS and WILLIAM N. KRIGSTEN, Chicago.
Discussion to be opened by WILLIS C. CAMPBELL, Memphis, Tenn., and ARTHUR T. LEGG, Boston.

Tuberculosis of the Knee in Infancy and Childhood (Lantern Demonstration). FRANCIS M. MCKEEVER, Los Angeles.
Discussion to be opened by W. P. BLOUNT, Milwaukee, and R. B. OSGOOD, Boston.

Low Back Pain: Correlation of the Signs and Symptoms of the Various Noninfectious Lesions (Lantern Demonstration). JOSEPH A. FREIBERG, Cincinnati.
Discussion to be opened by PHILIP LEWIN, Chicago, and G. C. BATTALORA, New Orleans.

The Cook Fenestrated Jacket for Correction of Scoliosis (Lantern Demonstration).
CARL E. BADGLEY and M. JOHN ROWE JR., Ann Arbor, Mich.
Discussion to be opened by C. H. CREGO JR., St. Louis, and L. G. HOWARD, Boston.

Thursday, May 18—9 a. m.

Reconstructive and Stabilizing Surgery in the Treatment of Residual Suppurative Arthritis of the Hip Joint: A Study of Forty-Five Unselected Cases (Lantern Demonstration). HALFORD HALLOCK, New York.
Discussion to be opened by J. ALBERT KEY, St. Louis, and FRANK D. DICKSON, Kansas City, Mo.

Excision of Scapula: Report of a Case Showing Excellent Functional Result (Lantern Demonstration).
EDWIN W. RYERSON, Chicago.
Discussion to be opened by J. W. SEVER, Boston, and ROLAND HAMMOND, Providence, R. I.

Acute and Chronic Osteomyelitis: Bacteriologic, Pathologic and Clinical Studies (Lantern Demonstration).
A. R. SHANDS JR., Wilmington, Del., and LENOX D. BAKER, Durham, N. C.
Discussion to be opened by JAMES B. WEAVER, Kansas City, Mo., and W. S. DUNCAN, Cleveland.

Chairman's Address: Simplified Internal Fixation of Inlay and Onlay Bone Grafts (Lantern Demonstration).
OSCAR L. MILLER, Charlotte, N. C.

Diagnosis and Treatment of Slipped Epiphyses (Lantern Demonstration).
RALPH K. GHORMLEY and ROBERT D. FAIRCHILD, Rochester, Minn.
Discussion to be opened by PHILIP D. WILSON, New York, and J. T. NICHOLSON, Philadelphia.

Imbalance of the Foot (Lantern Demonstration).
REX L. DIVELEY, Kansas City, Mo.
Discussion to be opened by J. E. M. THOMSON, Lincoln, Neb., and H. R. BOHLMAN, Baltimore.

Friday, May 19—9 a. m.

Election of Officers

Compression Reconstruction of Recent Intracapsular Femoral Neck Fractures: Internal Fixation by Universal Length Z Nail (Lantern Demonstration).
VERNON P. THOMPSON and JOHN S. STEPHENS, Los Angeles.
Discussion to be opened by V. L. HART, Minneapolis, and F. W. CARRUTHERS, Little Rock, Ark.

Severe Fractures of the Upper Ulna (Lantern Demonstration). W. K. WEST, Oklahoma City.
Discussion to be opened by J. T. O'FERRALL, New Orleans, and EUGENE M. REGEN, Nashville, Tenn.

A Study of Amputations in the Lower Extremities (Lantern Demonstration).
PAUL C. COLONNA and FREDERICK H. VOM SAAL, Oklahoma City.
Discussion to be opened by R. G. PACKARD, Denver, and R. M. CLEARY, Buffalo.

Sideswipe Fractures at the Elbow (Lantern Demonstration). ROBERT D. SCHROCK, Omaha.
Discussion to be opened by G. O. EATON, Baltimore, and R. C. ROBERTSON, Chattanooga, Tenn.

Primary Operative Reduction of Fractures of Long Bones as a Method of Choice: An Evaluation of Principles (Lantern Demonstration). CLAY RAY MURRAY, New York.
Discussion to be opened by H. EARLE CONWELL, Birmingham, Ala.; M. L. KLINEFELTER, St. Louis, and PAUL B. MAGNUSON, Chicago.

Treatment of Supracondylar Fractures of the Femur by Manipulation and Acute Flexion (Lantern Demonstration).
L. D. SMITH, Milwaukee.
Discussion to be opened by J. D. WILSON, Columbus, Ohio, and C. F. CLAYTON, Fort Worth, Texas.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

MEETS IN IVORY ROOM OF HOTEL JEFFERSON

OFFICERS OF SECTION

Chairman—DESCUM C. MCKENNEY, Buffalo.

Vice Chairman—A. H. AARON, Buffalo.

Secretary—J. A. BARGEN, Rochester, Minn.

Executive Committee—LOUIS A. BUIE, Rochester, Minn.; HENRY L. BOCKUS, Philadelphia; DESCUM C. MCKENNEY, Buffalo.

The annual banquet of the section will be held on Thursday, May 18, 6:30 p. m., in the Crystal Room of the Hotel Jefferson.

Wednesday, May 17—2 p. m.

AIDS TO THE MANAGEMENT OF PEPTIC ULCER

A Comparative Study of Methods Utilized to Determine the Presence of Ulceration in the Gastrointestinal Tract (Lantern Demonstration).
A. L. LEVIN and MORRIS SHUSHAN, New Orleans.

Peptic Ulcer Treated by Posterior Pituitary Preparations: Clinical and Experimental Observations.
M. HILL METZ, ROBERT W. LACKEY, P. E. WIGBY, A. B. SMALL and C. O. PATTERSON, Dallas, Texas.

The Use of Hydrated Trisilicate of Magnesium for Peptic Ulcer (Lantern Demonstration).
MANFRED KRAEMER, Newark, N. J.
Discussion to be opened by WALTER L. PALMER, Chicago, and MAURICE FELDMAN, Baltimore.

THE ESOPHAGUS

The Management of Benign Strictures of the Esophagus (Motion Picture Demonstration).
PORTER P. VINSON, Richmond, Va.
Discussion to be opened by JOHN H. FITZGIBBON, Portland, Ore.

INTESTINAL PARASITES

The Incidence and Results of Treatment in Subclinical Amebiasis.
FRANK H. CONNELL and HARRY T. FRENCH, Hanover, N. H.
Discussion to be opened by JAMES L. BORLAND, Jacksonville, Fla.

SYSTEMIC CONDITIONS WITH GASTROINTESTINAL SYMPTOMS

The Role of the Gastrointestinal Tract in the Production of Cardiac Symptoms (Lantern Demonstration).
LLSTER M. MORRISON and WILLIAM A. SWALM, Philadelphia.
Psychosomatic Factors Concerned in Recurrent Diarrhea.
SIDNEY A. PORTIS and JACOB KASANIN, Chicago.
Geriatrics: Its relation to an Adequate Energy Producing and Protective Diet (Lantern Demonstration).
E. L. TUOHY, Duluth, Minn.
Discussion to be opened by SEALE HARRIS, Birmingham, Ala., and WILLIAM EGBERT ROBERTSON, Philadelphia.

Thursday, May 18—2 p. m.

Election of Officers

THERAPEUTIC ADVANCES IN DISEASE OF THE ILEOCECAL REGION

Appendicitis: Newer Methods of Treatment (Lantern Demonstration).
JOHN S. HORSLEY JR., GUY W. HORSLEY and J. SHELTON HORSLEY, Richmond, Va.
The Management of Patients with Diffuse Peritonitis Caused by Perforated Appendicitis (Lantern Demonstration).
THEW WRIGHT, A. H. AARON, J. SUTTON REGAN and ELMER MILCH, Buffalo.
Ileocecal Spasm: The Cause for the Appendicular Syndrome (Lantern Demonstration).
BENJAMIN M. BERNSTEIN, Brooklyn.
Discussion to be opened by *J. DERYL HART, Durham, N. C.*

STUDIES ON CANCERS AT DIFFERENT AGES

The Importance of Carcinoma as a Cause of Indigestion (Lantern Demonstration).
ANDREW B. RIVERS, Rochester, Minn.
Cancer of the Rectum in Young Persons (Lantern Demonstration).
CURTICE ROSSER and J. G. KERR, Dallas, Texas.
Discussion to be opened by BURRILL B. CROHN and HENRY A. RAFSKY, New York.

IMPORTANT POINTS IN THE MANAGEMENT OF NEOPLASMS OF THE LARGE INTESTINE

Polyps of the Colon and Rectum and Their Relation to Malignancy (Lantern Demonstration).
NEIL W. SWINTON and SHIELDS WARREN, Boston.
The Lynch Versus the Miles Operation (Lantern Demonstration).
JEROME M. LYNCH and G. JOHNSON HAMILTON, New York.
The Advantages of Perineal Over Abdominal Colostomy with Technic for Transferring the Abdominal Opening to the Perineum (Lantern Demonstration).
W. WAYNE BABCOCK, Philadelphia.
Discussion to be opened by CLAUDE F. DIXON, Rochester, Minn.

Friday, May 19—2 p. m.

JOINT MEETING WITH SECTION ON RADIOLOGY IN BALL ROOM OF HOTEL DE SOTO

THE SMALL INTESTINE: ANATOMIC, ROENTGENOLOGIC, PATHOLOGIC AND CLINICAL CONSIDERATIONS

The Roentgen Anatomy of the Small Intestine (Lantern Demonstration).
GEORGE W. CHAMBERLIN, Philadelphia.
The Roentgenologic Manifestations of Non-Neoplastic Lesions of the Small Intestine (Lantern Demonstration).
HARRY M. WEBER, Rochester, Minn.
The Small Intestine in Nutritional Deficiency (Lantern Demonstration).
DAVID ADLERSBERG and MICHAEL WEINGARTEN, New York.
Epidemic Enteritis: Etiology and Relation to Other Infections of the Small Intestine (Lantern Demonstration).
E. C. ROSENOW, Rochester, Minn.
Clinical Aspects of Chronic Disorders of Small Intestine (Lantern Demonstration).
EVERETT D. KIEFER, Boston.
Discussion to be opened by T. GRIER MILLER, Philadelphia; SARA M. JORDAN, Boston, and ROSS GOLDEN, New York.

SECTION ON RADIOLOGY

MEETS IN BALL ROOM OF HOTEL DE SOTO

OFFICERS OF SECTION

Chairman—R. G. TAYLOR, Los Angeles.
Vice Chairman—MERRILL C. SOSMAN, Boston.
Secretary—JOHN T. MURPHY, Toledo, Ohio.
Executive Committee—ROSS GOLDEN, New York; B. R. KIRKLIN, Rochester, Minn.; R. G. TAYLOR, Los Angeles.

Wednesday, May 17—2 p. m.

Experimental Peritonitis: Its Prevention by Roentgen Therapy (Lantern Demonstration).
W. A. ALTEMEIER and H. C. JONES, Detroit.
Visualization of the Chambers of the Heart, the Pulmonary Circulation and the Great Blood Vessels in Man: Further Observations (Lantern Demonstration).
GEORGE P. ROBB and ISRAEL STEINBERG, New York.
Chairman's Address: Anomalies of the Sacrolumbar Articulations (Lantern Demonstration).
R. G. TAYLOR, Los Angeles.
The Treatment of Carcinoma of the Ovary (Lantern Demonstration).
ROBERT I. WALTER, ARNOLD L. BACHMAN and WILLIAM HARRIS, New York.
Bronchiogenic Carcinoma: A Diagnostic Enigma (Lantern Demonstration).
EDWARD L. JENKINSON and ARTHUR F. HUNTER, Chicago.
Discussion to be opened by LEROY SANTE, St. Louis.
Angio-Endothelioma of Bone (Lantern Demonstration).
J. FLETCHER LUTZ and LEWIS C. PUSCH, York, Pa.

Thursday, May 18—2 p. m.

Election of Officers

Neurologic Aspects of Intervertebral Disk Protrusions (Lantern Demonstration).
R. GLEN SPURLING and F. KEITH BRADFORD, Louisville, Ky.
Myelography with the Use of *Thorium Dioxide* Sol as a Contrast Medium (Lantern Demonstration).
B. H. NICHOLS and WILLIAM A. NOSIK, Cleveland.
The Diagnosis of Intervertebral Disk Protrusions by Intraspinal Injection of Air.
W. EDWARD CHAMBERLAIN and BARTON R. YOUNG, Philadelphia.
The Roentgenologic Diagnosis of Intraspinal Protrusion of the Intervertebral Disks by Means of Radiopaque Oil (Lantern Demonstration).
JOHN D. CAMP, Rochester, Minn.
Protruded Intervertebral Disks, with a Note Regarding Hypertrophy of Ligamenta Flava (Lantern and Motion Picture Demonstration).
J. GRAFTON LOVE, Rochester, Minn.

Friday, May 19—2 p. m.

JOINT MEETING WITH SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

THE SMALL INTESTINE: ANATOMIC, ROENTGENOLOGIC, PATHOLOGIC AND CLINICAL CONSIDERATIONS

The Roentgen Anatomy of the Small Intestine (Lantern Demonstration). GEORGE W. CHAMBERLIN, Philadelphia.
The Roentgenologic Manifestations of Non-Neoplastic Lesions of the Small Intestine (Lantern Demonstration).
HARRY M. WEBER, Rochester, Minn.
The Small Intestine in Nutritional Deficiency (Lantern Demonstration).
DAVID ADLERSBERG and MICHAEL WEINGARTEN, New York.

Epidemic Enteritis: Etiology and Relation to Other Infections of the Small Intestine (Lantern Demonstration). E. C. ROSENOW, Rochester, Minn.

Clinical Aspects of Chronic Disorders of Small Intestine (Lantern Demonstration). EVERETT D. KIEFER, Boston.
Discussion to be opened by T. GRIER MILLER, Philadelphia; SARA M. JORDAN, Boston, and ROSS GOLDEN, New York.

SECTION ON MISCELLANEOUS TOPICS, SESSION ON ANESTHESIA

MEETS IN BALL ROOM OF HOTEL DE SOTO

OFFICERS OF SECTION

Chairman—RALPH M. WATERS, Madison, Wis.

Secretary—CHARLES N. COMBS, Terre Haute, Ind.

Wednesday, May 17—9 a. m.

Chairman's Address. RALPH M. WATERS, Madison, Wis.

The Effect of Certain Anesthetics on the Blood (Lantern Demonstration). PAUL W. SEARLES, Buffalo.
Discussion to be opened by CHARLES J. BEILACH, Chicago.

The Principles of Inhalation Anesthesia for Thoracic Surgery. E. A. ROVENSTINE, New York.
Discussion to be opened by JOSEPH W. GALE, Madison, Wis.

Prevention of Ignition of Anesthetic Gases by Static Spark (Lantern Demonstration). PHILIP D. WOODBRIDGE, Boston.
Discussion to be opened by EVERETT A. TYLER, Philadelphia, and RALPH M. WATERS, Madison, Wis.

Trichlorethanol: A Preliminary Clinical Report (Lantern Demonstration). PAUL M. WOOD, New York.
Discussion to be opened by P. K. KNOEFEL, Louisville, Ky.

Intravenous Pentothal (Lantern Demonstration).
HENRY S. RUTH, Merion Station, Pa., and RALPH M. TOVELL, Hartford, Conn.
Discussion to be opened by GEORGE J. THOMAS, Pittsburgh.

Acapnial Shock: Its Relation to Narcosis (Lantern Demonstration). M. H. SEEVERS, Madison, Wis.
Discussion to be opened by HENRY K. BEECHER, Boston.

Oxygen Tolerance Versus Oxygen Dosage. JOHN H. EVANS, Buffalo.
Discussion to be opened by F. A. D. ALEXANDER, Albany, N. Y.

Direct Arterial and Venous Pressure Measurements During Clinical Anesthesia (Lantern Demonstration).
P. P. VOLPITTO, R. A. WOODBURY and W. F. HAMILTON, Augusta, Ga.
Discussion to be opened by John S. LUNDY, Rochester, Minn.

THE SCIENTIFIC EXHIBIT

". . . to teach them this art, if they should wish to learn it, without fee or stipulation . . ."

Two hundred and forty small "classrooms," all in session at the same time; a "faculty" of more than five hundred of the leading investigators, teachers and practitioners of medicine; a "student body" of seven or eight thousand physicians from the United States and other countries—that is the Scientific Exhibit of the American Medical Association as it will appear at the St. Louis Session.

The year 1939 marks the fortieth anniversary of the Scientific Exhibit. Credit for its establishment goes to members of the Indiana State Medical Association. In 1899 they brought to the meeting of the American Medical Association at Columbus, Ohio, a considerable amount of exhibit material from their own state meeting which had just taken place at Indianapolis. Such interest was created that a committee was appointed for the continuation of the feature. At first the exhibits were confined to specimens of pathologic anatomy, but in 1903 their scope was broadened to include all phases of medicine and the term "Scientific Exhibit" applied.

The Scientific Exhibit constitutes an intensive week of postgraduate medical instruction. The trustees of this unique educational institution are the Trustees of the American Medical Association, who appoint three of their own members as the "Committee on Scientific Exhibit" and appropriate many thousands of dollars annually for its maintenance. A strong advisory committee, together with representatives from the fifteen sections of the Scientific Assembly of the Association, insures a high standard of excellence from the educational standpoint.

Physicians are given an excellent opportunity in the Scientific Exhibit for study and conference. Demonstrators are on hand at all times to answer questions and explain the work portrayed. Many of the papers read before various sections of the Scientific Assembly are illustrated by exhibits, making it possible for the physician who has heard the report to come to the Scientific Exhibit for further information on the subject.

The fifteen sections of the Scientific Assembly are represented in the Scientific Exhibit, with exhibits grouped by specialties. The purpose of the meeting, however, is for the benefit of the physician in general practice rather than of the specialist, although the latter will find plenty to occupy his time, for each exhibit is presented by a specialist in one field or another.

There will be several interesting features at the St. Louis Session. The special exhibits on fractures and on anesthesia will include much practical material; the exhibit symposium on heart disease will cover the subject quite completely; the exhibit symposium on medical education, hospitals and licensure is devoted largely to graduate medical education as it is conducted by different state medical associations. Motion picture programs will be conducted continuously and simultaneously by several of the sections in commodious areas adjacent to the exhibits.

Graduate medical education is the theme of the Scientific Exhibit. Nowhere is the Oath of Hippocrates better exemplified than by the participants in the Scientific Exhibit who give freely of their time and energy for the benefit of other physicians.

The Scientific Exhibit is located in the Convention Hall of the St. Louis Municipal Auditorium, on the same floor as the Opera House and on the floor above the Technical Exhibit. It is reached from the Technical Exhibit by ramps and elevators.

Admission to the Scientific Exhibit will be limited to persons wearing Fellowship or other badges of the convention and to guests to whom special cards of admission have been issued. The public will not be admitted to the Scientific Exhibit.

SPECIAL EXHIBIT ON ANESTHESIA

The exhibit on anesthesia is presented for the third time this year under the auspices of a committee appointed by the Committee on Scientific Exhibit of the Board of Trustees as follows: John S. Lundy, Rochester, Minn.; Henry S. Ruth, Philadelphia; Philip D. Woodbridge, Boston, and Ralph M. Waters, chairman, Madison, Wis.

An additional advisory committee is comprised of A. M. Caine, New Orleans; John Evans, Buffalo; A. E. Guedel, Los Angeles; Huberta M. Livingstone, Chicago; G. S. Mechling, Oklahoma City; F. T. Romberger, Lafayette, Ind.; A. L. Schwartz, Cincinnati; L. F. Sise, Boston; B. C. Sword, New Haven, Conn.; G. J. Thomas, Pittsburgh; Dorothy Wood, San Francisco, and Paul M. Wood, New York.

The exhibit deals with the administration of anesthetics as under the following topics:

1. The airway.
2. Open drop technic.
3. Open and semiopen technics for administration of gases, and apparatus required.
4. Carbon dioxide absorption technic, and apparatus required.
5. Rectal technic.
6. Intravenous technic.
7. Various local and block technics.
8. Principles and method of record keeping.

Demonstrations will be given continuously throughout the week, and motion pictures will be shown in an area adjacent to the exhibit. A pamphlet will be distributed.

The following anesthetists will take part in the demonstration:

John A. Adriani, New York, N. Y.
F. A. D. Alexander, Albany, N. Y.
Virginia Apgar, New York, N. Y.
Henry Beecher, Boston, Mass.
C. M. Betlach, Chicago, Ill.
H. F. Bishop, Valhalla, N. Y.
R. F. Bonham, Houston, Texas
R. F. Corwin, Dayton, Ohio
S. C. Cullen, Iowa City, Iowa
Hugh Cunningham, Milwaukee, Wis.
Lilly Dismuke, New Orleans, La.
H. E. Doudna, Oklahoma City, Okla.
W. B. Draper, Denver, Colo.
H. S. Eggers, Louisville, Ky.
Urban Eversole, Boston, Mass.
B. Herzberg, Phoenix, Ariz.
J. H. Hutton, Portland, Ore.
J. Kreiselman, Washington, D. C.
S. S. Lyons, New York, N. Y.
W. B. Neff, San Francisco, Calif.
George Paschal, San Antonio, Tex.
G. M. Rosenheimer, South Bend, Ind.
P. W. Searles, Buffalo, N. Y.
Gladys Smithwick, Lexington, Ky.
J. A. Stiles, San Francisco, Calif.
T. L. Tidmore, Atlanta, Ga.
R. M. Tovell, Hartford, Conn.
P. P. Volpitto, Augusta, Ga.
R. J. Whitacre, E. Cleveland, Ohio

SPECIAL EXHIBIT ON FRACTURES

The exhibit on fractures is continued again this year along somewhat the same lines as last year. The special exhibit committee appointed by the Committee on Scientific Exhibit of the Board of Trustees is composed of the following: Frank D. Dickson, Kansas City, Mo.; Walter Estell Lee, Philadelphia; Kellogg Speed, chairman, Chicago.

The following subjects will be considered:

1. Plaster of Paris: Making and Storing.
2. Application of Plaster of Paris.
3. Fracture of the Lower End of the Radius.
4. Fracture of the Spine—Compression.
5. Supracondylar Fracture of the Humerus.
6. Emergency Treatment of Fractures of the Lower Extremity.

Demonstrations will be given continuously throughout the week. A pamphlet has been prepared for distribution in connection with the exhibit.

The following physicians will take part in the demonstration:

George Apfelbach, Chicago, Ill.
G. W. Batman, Indianapolis, Ind.
G. C. Battalora, New Orleans, La.
Carl E. Black, Jacksonville, Ill.
Mat Bloomfield, Joliet, Ill.
W. P. Blount, Milwaukee, Wis.
George K. Carpenter, Nashville, Tenn.
Dwight F. Clark, Evanston, Ill.
C. F. Clayton, Fort Worth, Texas
George J. Curry, Flint, Mich.
R. J. Dittrich, Fort Scott, Kans.
James R. Elliott, Kansas City, Mo.
Egbert G. Fell, Chicago, Ill.
C. R. G. Forrester, Chicago, Ill.
Clarence B. Francisco, Kansas City, Mo.
Alfred E. Gallant, Los Angeles, Calif.
Halford Hallock, New York, N. Y.
Maxwell Harbin, Cleveland, Ohio
V. L. Hart, Minneapolis, Minn.
Frederick A. Jostes, St. Louis, Mo.
M. L. Klinefelter, St. Louis, Mo.
Jacob Kulowski, St. Joseph, Mo.
James W. Martin, Omaha, Neb.
Thomas E. Meany, Chicago, Ill.
Earl D. McBride, Oklahoma City, Okla.
Duncan McKeever, Kansas City, Mo.
Arthur R. Metz, Chicago, Ill.
Herbert P. Miller, Rock Island, Ill.
R. J. Mroz, Rockford, Ill.
Frank G. Murphy, Chicago, Ill.
Jesse Nicholson, Philadelphia, Pa.
L. M. Overton, Des Moines, Iowa
E. Payne Palmer, Phoenix, Ariz.
Francis G. Pipkin, Kansas City, Mo.
Darwin B. Pond, Chicago, Ill.
Willis J. Potts, Oak Park, Ill.
M. E. Pusitz, Topeka, Kans.
Sheppard Remington, Chicago, Ill.
Dean L. Rider, Chicago, Ill.
R. C. Robertson, Chattanooga, Tenn.
Charles Rombold, Wichita, Kans.
L. D. Smith, Milwaukee, Wis.
Charles A. Stone, St. Louis, Mo.
W. G. Stuck, San Antonio, Tex.
Henry B. Thomas, Chicago, Ill.
John R. Tobin, Elgin, Ill.
D. R. Ulmer, Terre Haute, Ind.
H. W. Virgin Jr., Madison, Wis.
W. K. West, Oklahoma City, Okla.
C. E. Yount, Prescott, Ariz.

SECTION EXHIBITS

Section on Practice of Medicine

The Section on Practice of Medicine, in addition to a large number of exhibits on various phases of internal medicine, presents groups of exhibits on arthritis, on the endocrines and on pneumonia. The section is likewise contributing to the Exhibit Symposium on Heart Disease. The representative to the Scientific Exhibit from the Section on Practice of Medicine is Fred M. Smith, Iowa City.

ROBERT M. STECHER, City Hospital, Cleveland:

Heberden's Nodes; The Incidence of Hypertrophic Arthritis of the Fingers: Exhibit of photographs, charts and explanatory matter illustrating the clinical appearance of Heberden's nodes and showing the incidence of the disease; incidence analyzed by race, sex, age and occupation; two families with five and four siblings having severe Heberden's nodes presented; from the incidence of the disease for the age, sex and degree of severity of the condition for each of these individuals the probability of such family involvement has been calculated; a strong familial susceptibility is demonstrated.

OLIVER ABEL JR. and WALTER J. SIEBERT, St. Louis:

Fibrositis; The Chief Cause of Pain in Rheumatism: Exhibit of slides and charts showing laboratory data and roentgen studies; treatment by vaccines, physical therapy and the like, with results of treatment; associated fibrositis, the principal cause of pain in hypertrophic osteo-arthritis.

K. K. SHERWOOD, Seattle.

Diagnosis of Chronic Arthritis: Exhibit of colored drawings and photomicrographs illustrating the cardinal differences between hypertrophic and atrophic arthritis; analysis of the symptoms in a series of 250 cases of atrophic and 250 cases of hypertrophic arthritis arranged to emphasize the points of differentiation; physical changes similarly compared emphasizing the different joint distribution of the disease; analysis of the symptoms of physical changes of 250 patients who thought they had rheumatism but in whom the main disease was proved nonarthritic, emphasizing the frequent points of differentiation; summary of the symptoms and signs of adult tuberculosis of the bones, of metastatic tumors of the bones, of primary bone tumors and of Paget's disease.

F. LOWELL DUNN and E. E. SIMMONS, Omaha:

Fever Therapy in Rheumatic Fever: Exhibit of transparent charts and photographs of the results of fever therapy in rheumatic fever, including the effect on sedimentation rate and rheumatic carditis; motion picture of technic of fever therapy with Kettering type of cabinet, and of cases of rheumatic carditis.

ELLIOTT P. JOSLIN and HOWARD F. ROOT, Boston, with LOUIS I. DUBLIN and HERBERT H. MARKS, New York:

The Current Diabetes Situation: Exhibit of charts of existing trends in the incidence, diagnosis, prognosis, mortality and treatment of diabetes and its complications with especial emphasis on the prevention and early detection of the disease.

ELMER L. DEGOWIN, JOHN E. HARRIS and E. D. PLASS, State University of Iowa, University Hospitals, Iowa City:

Preservation of Blood for Transfusion: Exhibit of specimens of human blood drawn and stored in Iowa City and subsequently transported to St. Louis; rates of hemolysis in different preservatives are demonstrated; colored charts depicting the following chemical and physical changes at various ages of storage: (1) hemoglobin in plasma, (2) potassium in plasma, (3) dextrose content of plasma, (4) specific conductance of plasma, (5) p_H of plasma, (6) respiratory activity of erythrocytes, (7) studies on blood preserved anaerobically, the optimum conditions and preservatives for storage.

J. RUSSELL TWISS, R. FRANKLIN CARTER and CARL H. GREENE, New York:

Biliary Colic: Etiology, Diagnostic Significance and Treatment: Exhibit showing that intermittent attacks of acute pain originating in the biliary tract are usually considered to be caused by gallstones, but experimental work and clinical experience have proved that colic may occur without stones; recurrent colic following cholecystectomy constitutes a major problem in the management of disease of the biliary tract; study of biliary colic has therefore been made which includes a review of recent concepts concerning its physiologic origin; charts are presented summarizing the clinical and operative conditions in 140 cases of biliary colic in patients with and without gallstones; similar charts are presented of forty cases presenting colic following cholecystectomy; an analysis of the methods of determining the cause of the colic and its treatment are given in each group with general conclusions based on these observations.

W. M. FOWLER and ADELAIDE P. BARER, University Hospitals, Iowa City:

Metabolism and Therapeutic Use of Iron: Exhibit of drawings, charts and graphs presenting data on the metabolism of iron, showing the amount absorbed and utilized with varying dosages and the therapeutic effect in certain types of anemia.

JOHN D. CURRENCE, New York Post-Graduate Medical School and Hospital, Columbia University, New York:

Hyperpyrexia: Exhibit of charts depicting factors in fever therapy such as rationale, indications, contraindications, physiologic effects, methods of application, complications of hyperpyrexia, preparation of patient, pathologic changes in fatal cases, mechanism of shock caused and its treatment, and specific applications.

ROBERT OLESEN, U. S. Public Health Service, Washington, D. C.:

Pneumonia Control: Exhibit of posters depicting by pictorial and graphic means the principal points in the control of pneumonia.

M. HERBERT BARKER, the Department of Medicine of Northwestern University Medical School, and O. H. ROBERTSON, the Department of Medicine, the University of Chicago, Chicago.

Pneumonia: Exhibit reviewing the modern concept of pneumonia, its etiology, pathogenesis, pathology, epidemiology, general and specific therapy in detail and the Illinois state control program; presentation by means of models, roentgen studies, photomicrographs, illustrative placards and motion pictures.

DAVID J. COHN, Michael Reese Hospital, Chicago:

The Biology, Chemistry and Physics of Oxygen Therapy: Exhibit of charts and mechanical demonstrations illustrating the fundamental principles underlying the therapeutic administration of oxygen, such as the partial pressure relationships between the gases in the atmosphere, the alveoli, the blood and the tissues, as well as the chemistry of the hemoglobin-oxygen-carbon dioxide cycle; charts and models illustrating the basic physical and engineering principles, knowledge of which is necessary for the scientific construction of oxygen therapy apparatus, including the laws of heat transfer, hygrometry and the diffusion of gases in the atmosphere and through materials; methods of gas analysis in the air and in the blood and tissues.

WILLIAM WASHINGTON GRAVES, St. Louis University School of Medicine, St. Louis:

Human Constitution: New Approaches to the Problems (Inherited Variations and "The Age-Incidence" Principle): Exhibit dealing with new approaches to the problems of human constitution based on (1) simple classifications of variations peculiar to inherited characters of structure, function, measurements and indexes; (2) the application of "the age-incidence principle of investigation" in qualitatively evaluating them; (3) a summary of results derived from the application of the author's classification of human scapulae and (4) the classification of other inherited variations which, when adequately investigated, may become, like scapular types, useful in the problems of human constitution as expressed in inherited predisposition to health or disease and inherited capacities for educability, adaptability in general and longevity.

HAYNES H. FELLOWS and WILLIAM H. ORDWAY, Metropolitan Life Insurance Company, New York:

Pulmonary Tuberculosis; A Long Range Program for Control Among Personnel: Exhibit of (1) case finding with description of the routine and periodic search for early cases of pulmonary tuberculosis among employees and applicants for employment, with special emphasis on the experience with fluoroscopy; (2) sanatorium care for the patient until he is ready to return to work; (3) rehabilitation by restoring patients to their former jobs or placing them in similar work; (4) results obtained in each phase of this program; influence of certain factors on the working capacity subsequent to discharge, namely, stage of tuberculosis on admission to the sanatorium and condition on discharge; mortality rates subsequent to discharge from the sanatorium as related to these factors.

G. O. BROUN, K. R. ANDREWS and M. J. HUBER, St. Louis University School of Medicine, St. Louis:

Prevention of Cholesterol Atherosclerosis in the Rabbit; Comparison of Preventive Action of Lipocaic and Choline: Exhibit of (*a*) gross specimens of the aorta of rabbits fed normal diet, fed high cholesterol diet, fed high cholesterol diet plus lipocaic in varying amounts and fed high cholesterol diets and choline in varying amounts; (*b*) photomicrographs of aorta of same series of animals; (*c*) charts showing blood cholesterol changes of the same series of animals.

AUGUST A. WERNER, St. Louis:

Sex Hormones, Clinical Studies: Exhibit showing the effects of the sex-related hormones on human beings, including the production of the growth phase in the endometrium of castrate women by administration of theelin (estrogenic substance) and the development of the premenstrual endometrium in castrate women by injections of theelin and progesterone; the syndrome complained of by castrates, women having hypo-ovarianism, the menopause and involutional melancholia; the male climacteric and its treatment with testosterone propionate; cryptorchidism and its treatment with anterior pituitary gonadotropic extract and anterior pituitary-like substance.

ROBERT E. SCHLUETER and ETHEL A. WASHBURN, St. Louis:

Medical History: Exhibit of pictures and other objects of importance in medical history pertaining to early medicine in St. Louis and Missouri.

HENRY H. TURNER, Oklahoma City:

Clinical Endocrinology: Exhibit of photographs illustrating various accepted types of endocrinopathies and the results of treatment, a syndrome of infantilism, webbed neck and cubitus valgus; results of some original work in the treatment of hypogonadism with testosterone propionate; effects of the anterior pituitary-like substances in the treatment of acne and cretinism, some of which have been observed and treated over a period of from ten to twelve years, and numerous other clinical endocrinopathies.

BENSON BLOOM and C. S. KIBLER, Tucson, Ariz., and S. J. GRAUMAN, Milwaukee:

Potassium in Hay Fever: Exhibit of charts showing effect of potassium chloride in various allergic conditions; demonstration of effect of potassium chloride on hay fever.

DANIEL L. SEXTON, St. Louis:

Hormone Treatment in Cryptorchidism and Hypogenitalism: Exhibit of cases of cryptorchidism and hypogenitalism in boys ranging in age from 5 to 23 years; comparison of the results of treatment with the anterior pituitary-like hormone (A. P. L.) and the male sex hormone (testosterone propionate).

Section on Surgery, General and Abdominal

The Section on Surgery, General and Abdominal, in addition to its other exhibits, is presenting a group of exhibits on cancer, together with a continuous motion picture on various surgical subjects in an adjoining area. The representative from this section to the Scientific Exhibit is Grover C. Penberthy, Detroit.

CONRAD J. BAUMGARTNER, Los Angeles:

Lesions of the Neck: Exhibit showing moulages of lesions of the neck; models made primarily to be used for teaching purposes and as a supplement and substitute for clinical material accompanying lectures on lesions of the neck.

WALTER M. BOOTHBY, C. W. MAYO, W. R. LOVELACE and A. H. BULBULIAN, Rochester, Minn.:

The Use of Oxygen in Medicine, Surgery and Aviation; Historical Development; A New Method of Administration: Exhibit of photographs illustrating the historical development of oxygen therapy and a detailed description of a new type of simple inhalation apparatus by means of which oxygen can be administered efficiently and economically either in the home or in the hospital; the value of high concentrations of oxygen approximating 100 per cent in contrast to the usual well known utilization of concentrations of from 50 to 60 per cent; it is of special value in pulmonary embolism, coronary thrombosis, post-surgical and traumatic shock, preventing headache following encephalography, relieving abdominal distention and aiding in the control of gas gangrene and tetanus.

FRANK J. TAINTER, St. Louis University School of Medicine, St. Louis:

Oral and Plastic Surgery: Exhibit of wax casts of faces; drawings of plastic operations; magic lantern slides of bone grafts of the jaw.

CHARLES F. SHERWIN and A. M. TRIPODI, St. Louis University School of Medicine, St. Louis:

General, Plastic and Tumor Surgery: Exhibit of photographs and drawings of interesting surgical cases, plastic surgery and tumors; repair of old muscle tendon avulsions, congenital diaphragm of duodenum, plastic reconstruction of lower lip; experimental pancreatic surgery.

HARRY E. MOCK and John L. LINDQUIST, Chicago:

Skull Fractures and Cerebral Injuries: Exhibit of charts, plaster models, paintings and drawings and roentgenograms depicting the management of skull fractures and cerebral

injuries, based on a review of proved skull fractures; simple methods and necessary views to be taken to demonstrate the presence of a skull fracture; cerebral pathologic changes following injury; diagnosis of conditions causing prolonged unconsciousness.

WILLIAM T. COUGHLIN, St. Louis University School of Medicine, St. Louis:

Correction of Deformities of Hard and Soft Parts of Face: Exhibit of drawings, photographs, transparencies, plaster of paris impressions, apparatus and the like showing the steps in the various procedures necessary for the repair of defects of the bony skeleton and soft parts of the face.

JAMES L. MUDD, St. Louis University School of Medicine, St. Louis:

Lobectomy for Bronchiectasis: Exhibit of roentgen films of the chest showing preoperative and postoperative bronchography, case histories (on transparencies), photographs and photomicrographs of pathologic specimens.

HILGER PERRY JENKINS, LEO HRDINA and FOREST M. SWISHER, Chicago:

Comparative Study of Catgut and Silk: Exhibit of transparencies of photographs and photomicrographs demonstrating a histologic study of the reaction of the tissues to silk and to different kinds of catgut carried out from specimens removed from patients at operation or obtained at autopsy; specimens obtained from implants of assorted suture material in abdominal muscles of dogs; the rate of healing of wounds sutured with catgut and silk in the presence of contamination; osteogenesis in healed laparotomy incisions of patients.

CLAIRE L. STRAITH and E. HOYT DEKLEINE, Detroit:

Plastic Surgery in Children: Exhibit of enlarged photographs depicting various deformities occurring in children and the results obtained by plastic procedures, with inserts and captions describing the technic used to accomplish the result; demonstration of the great advantage of operating on childhood deformities as early as practicable to minimize or avoid the inferiority complexes which so often develop in these children and sometimes produce marked personality changes.

ROBERT ELMAN, CHARLES L. HOAGLAND, L. H. HEMPLEMANN JR. and WILSON G. BROWN, Washington University School of Medicine, St. Louis:

Acute Pancreatic Disease: Exhibit demonstrating a rapid clinical method for the detection of acute pancreatic disease by measuring the concentration of blood amylase; curves showing the behavior of blood amylase during the course of the disease; plastic models showing the relation of the pancreatic and bile ducts in the human being, illustrating the probable pathogenesis; charts and specimens suggesting the appropriate treatment and the importance of differentiating pancreatic necrosis from transient inflammation.

ALBERT BEHREND, HELENA E. RIGGS, MOSES BEHREND and JEFFERSON H. CLARK, Philadelphia:

Cerebral Complications Following Surgical Operations: Exhibit showing a full length human figure with organs in situ; photomicrographic colored transparencies; legends of explanation printed.

WILLIAM E. HOWES, JOSEPH TENOPYR, W. W. HALA, W. P. CORRIERO and IRVING SILVERMAN, Caledonian Hospital, Brooklyn.

Organization and Development of a Tumor Clinic in a Private Voluntary Hospital (100 Beds): Exhibit of charts showing personnel; records; apparatus, including surgical, laboratory, roentgen therapy and radium therapy requirements; biopsy, with two unique types of biopsy needles developed in the clinic; photomicrographs showing typical sections taken with these needles from breast, liver, lung and in some cases before and after irradiation; mortality statistics, including all cases enrolled in the two and one-half years since organization.

LOUIS H. JORSTAD and BRUCE C. MARTIN, St. Louis:

Tumors of the Head and Neck—Diagnosis and Treatment: Exhibit of moulages in natural colors of actual cases of benign and malignant tumors of the mouth, lip and face, demonstrating methods of treatment by radium and surgery, showing half of the face and corresponding half of the oral cavity sufficient for orientation; cases for surface and interstitial radium; procedures for immediate reconstruction of defects in selected cases; resection of lymph bearing tissue of the neck-draining areas of the head depicted in moulage; roentgenograms of benign and malignant tumors of the bones of the skull; photomicrographs of each type of lesion and a minimum of descriptive material.

W. E. ADAMS, Chicago:

Surgical Treatment of Intrathoracic Tumors: Exhibit of experimental and clinical studies, which include tumors involving most structures of the chest; i. e., chest wall, mediastinum, lung and esophagus.

WILLIAM J. HOFFMAN, New York:

Cancer; Its Treatment by Surgery and Irradiation: Exhibit of transparencies illustrating various types of cancer of the skin, lip, tongue, tonsil, hard palate, cheek, ear, nose, neck, breast, hands, lymph nodes of the neck, axilla and groin, and their treatment by surgery, irradiation and combinations of the two; indications for surgery and for irradiation illustrated and emphasized.

JEROME M. LYNCH and G. JOHNSON HAMILTON, New York:

Carcinoma of the Rectum and Sigmoid: Exhibit of charts, drawings, transparencies and photomicrographs depicting the manner of metastatic spread and the danger of biopsy; an operation is suggested which eradicates these danger points but still has a low mortality, illustrated by animated drawings and photographs of end results; various stages in the development of carcinoma are shown.

V. P. BLAIR, JAMES BARRETT BROWN and LOUIS T. BYARS, Washington University School of Medicine, St. Louis:

Cancer of the Mouth and Face: Exhibit of photographs showing lesions and diagnostic points; plans of treatment of typical instances.

EVARTS A. GRAHAM and BRIAN BLADES, Washington University School of Medicine, St. Louis:

Thoracic Surgery: Exhibit showing new developments in thoracic surgery, illustrated with photographs, charts, etc.

EARL C. PADGETT, Kansas City, Mo.:

The Calibrated Skin Graft; A New Principle and a New Type of Graft: Exhibit of translite films depicting typical operative results; demonstration of a new skin grafting machine; method of cutting skin in one sheet of absolutely uniform thickness from any area of the body in any pattern and of any thickness desired; motion picture demonstration.

IRWIN SCHULZ, W. P. BLOUNT, CHARLES FIDLER, G. WILLIAM FOX, ROBERT MONTGOMERY, ARTHUR A. SCHAEFER, A. C. SCHMIDT, H. C. SCHUMM and STANLEY J. SEEGER, Milwaukee Children's Hospital, Milwaukee:

Fractures in Children; Principles of Treatment: Exhibit of photographs, roentgenograms, diagrams and charts presenting an end result study of fractures of the humerus, elbow, forearm, femur and tibia in children; statistical summaries of the incidence, location and results; roentgenograms of representative cases; photographs of methods and comments regarding principles of treatment. The principles of treatment of fractures in adults cannot be applied to children; open reduction is contraindicated in most types of fracture and is urgently needed in others; adaptive changes which occur with growth must be fully appreciated in treating fractures in children.

BERNHARD STEINBERG, Toledo Hospital, Toledo, Ohio:

Stages in Peritonitis—Based on Defense Mechanism in Relation to Treatment: Exhibit showing that general peritonitis is divided into three stages: the primary stage in which the various defenses, cellular and humoral, are capable of mobilization (preventive treatment designed to mobilize effectively these elements is presented and a procedure outlined for a ready recognition); the second stage, one of bacterial multiplication and toxin production in which the defense mechanism is inhibited or paralyzed and the treatment of this stage is indicated; the third stage, one of irrevocable damage.

HAROLD M. TRUSLER and JAMES F. GLORE, Indiana University Medical Center, Indianapolis:

Treatment of Burns and the Repair of Burn Scar Deformities: Exhibit of charts, illustrations, and photographs concisely and coherently portraying four important phases in the treatment of major burns: (1) treatment of burn shock; (2) initial treatment of burned areas; (3) treatment of granulation tissue in preparation for skin grafting; (4) plastic repair of deformities and contractures due to burn scars, including illustrations of split skin grafting, Z-plasty, pedicle or rolled flap reconstruction and other major reconstructive surgical procedures.

R. H. JACKSON, J. N. SISK and A. S. JACKSON, Jackson Clinic, Madison, Wis.:

Diseases of the Gallbladder Ducts and Liver: Exhibit of models and charts illustrating diseases of the gallbladder and liver and the various steps in cholecystectomy; slides amplifying these conditions and illustrating the pathologic changes; technic of T-tube drainage of the common duct; charts and drawings demonstrating surgical methods used in treating disease of the biliary system; a study of anatomic variations of the cystic artery and a series of cholecystograms.

J. W. THOMPSON, St. Louis:

Experimental and Clinical Study of a New Suture Material: Exhibit of transparencies and drawings of microphotography of healing wounds, comparing the properties of a new suture material of a bovine membrane with catgut, silk and linen; drawings illustrating the technic of performing operations for hernia; photographs and transparencies showing end results in patients with hernia who have been operated on.

N. FREDERICK HICKEN and R. RUSSELL BEST, Omaha Clinic, Omaha:

Discharges from the Nipple: Their Clinical Significance and Diagnosis: Exhibit showing that spontaneous discharges from the nipple, other than during lactation, signify abnormal physiologic and pathologic changes; carcinoma, sarcoma, papilloma, degenerating benign tumors, mazoplasia, trauma, infection and cystic degeneration of the breast may or may not produce a discharge from the nipple; the escaping secretions may consist of blood serum, pus, altered milk and products of degenerating tumor or desquamating epithelial cells from the ducts, depending on the nature of the provocative factor; symptoms and physical changes are correlated by transilluminations, mammographies, roentgenologic and microscopic studies; classification and results of studies are presented by colored translites, drawings and moulages.

D. HENRY POER, Atlanta, Ga.:

Survey of Thyroid Diseases in Georgia: Exhibit of charts, graphs and translite photographs to show types and relative incidence of goiter; studies of hypothyroidism and cretinism; experimental studies in thyroparathyroidectomized animals; results in treatment of tetany with *ditachysterol*; blood iodine studies; statistical and pictorial study of thyroid diseases in a nonendemic area of the United States for comparative purposes.

ROLAND M. KLEMME, St. Louis:

Accurate Differential Section for Treatment of Trigeminal Neuralgia; Athetosis and Its Treatment: Exhibit of moulages and models of heads showing steps of operation and treatment of trigeminal neuralgia; charts of patients before and after operation.

JOSEPH FELSEN and BENJAMIN LEWIS, New York:

Acute Segmental Appendicitis: Experimental and Clinical Studies: Exhibit of gross photographs, photomicrographs, drawings and mounted specimens of rabbit and human appendixes showing acute segmental appendicitis as a pathologic and clinical study in the human being supplemented by the reproduction of characteristic lesions in rabbits by means of vascular occlusion, which may be the result of mechanical factors or the action of toxins or bacteria from a distant focus; the role of the indirect hematogenous excretory mechanism is stressed in intestinal infection; whether mechanical or excretory in origin, thrombosis of the appendical vessel is followed by a sharply segmental area of mucosal necrosis which corresponds to the distribution of the involved vessel; intramural bacterial invasion from the appendical lumen occurs with a tendency to fan-shaped spread toward the serosa.

HAROLD LINCOLN THOMPSON, Los Angeles:

Surgical Treatment of Peptic Ulcer: Exhibit of drawings illustrating the problems encountered in the surgical treatment of gastric and duodenal ulcer.

MANUEL GRODINSKY and EDWARD HOLYOKE, Omaha:

The Anatomic Basis of Deep Abscesses of the Head, Neck and Adjacent Regions: Exhibit of transparencies, made from (1) diagrammatic drawings based on dissections, injections and sections of human material, and (2) tracings on bleached photographs of sections of adult and fetal material; moulages made from transverse sections of adult material; posters explaining the transparencies and moulages, and indicating the clinical implications with special reference to Ludwig's angina, retropharyngeal abscess and other deep abscesses.

MOTION PICTURES

Motion pictures on surgery will be shown continuously in an area adjoining the exhibits by the following:

CONRAD J. BAUMGARTNER, Los Angeles:

JOSEPH F. JAROS, Chicago:

JEROME M. LYNCH, New York:

Section on Obstetrics and Gynecology

The representative to the Scientific Exhibit from the Section on Obstetrics and Gynecology is H. Close Hesseltine, Chicago.

A. LOUIS DIPPEL and WEBSTER H. BROWN, Johns Hopkins Hospital, Baltimore:

Roentgen Visualization of the Placenta in Placenta Praevia and Other Conditions: Exhibit of films showing that by means of soft tissue roentgen technic the placenta as well as the uterine wall may be readily visualized in pregnant women; in cases of suspected placenta praevia this method obviates the necessity of vaginal examination; exhibit based on sixty cases of suspected placenta praevia in which the placenta was localized by this method and placenta praevia either diagnosed or ruled out.

CON FENNING, University of Utah, Salt Lake City:

Indirect External Hysterography; Equipment and Recordings: Exhibit of equipment showing the compact, portable, completely self-contained unit and its individual components; four sets of representative recordings of uterine activity secured from the human being during various periods of pregnancy.

CHARLES EDWIN GALLOWAY and TOM D. PAUL, Evanston, Ill.:

Colored Photography of the Pathologic Cervix: Exhibit of photographs of various pathologic lesions shown as lantern slides in a view box and as colored pictures hung on the wall; projector showing lesions on a screen; camera for clinical photography work.

WYMAN C. C. COLE and DAVID C. KIMBALL, Detroit:

Etiologic Factors in Neonatal Asphyxia: Exhibit of charts, graphs and slide-film projection presenting a statistical and clinical analysis of 5,000 consecutive newborn babies delivered at the Woman's Hospital, Detroit; particular attention to the role of sedatives and anesthetics.
